- *psClusterInstance*: Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initializing individual structure fields.
- *bIsServer*: Type of cluster instance (server or client) to be created:
  - TRUE - server
  - FALSE - client
- *psClusterDefinition*: Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the Pressure Measurement cluster. This parameter can refer to a pre-filled structure called sCLD_``PressureM``easurement which is provided in the **PressureMeasurement.h** file.
- *pvEndPointSharedStructPtr*: Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_``PressureM``easurement, which defines the attributes of Pressure Measurement cluster. The function initializes the attributes with default values.
- *pu8AttributeControlBits*: Pointer to an array of **uint8** values, with one element for each attribute in the cluster (see above). For a cluster client, set this pointer to NULL.

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

Parent topic:*Pressure Measurement Cluster*

Return codes The Pressure Measurement cluster function uses the ZCL return codes defined in Section 7.2.

Parent topic:*Pressure Measurement Cluster*

Enumerations

'Attribute ID' Enumerations The following structure contains the enumerations used to identify the attributes of the Pressure Measurement cluster.

```
typedef enum
{
 E_CLD_PRESSUREMEAS_ATTR_ID_MEASURED_VALUE   = 0x0000,
 E_CLD_PRESSUREMEAS_ATTR_ID_MIN_MEASURED_VALUE,
 E_CLD_PRESSUREMEAS_ATTR_ID_MAX_MEASURED_VALUE,
 E_CLD_PRESSUREMEAS_ATTR_ID_TOLERANCE,
}teCLD_PM_ClusterID;
```

Parent topic: Enumerations

Parent topic:*Pressure Measurement Cluster*

Structures There are no structures specific to the Pressure Measurement cluster.

Parent topic:*Pressure Measurement Cluster*

Compile-time Options This section describes the compile-time options that may be enabled in the **zcl_options.h** file of an application that uses the Pressure Measurement cluster.

To enable the Pressure Measurement cluster in the code to be built, it is necessary to add the following line to the file:

```
#define CLD_PRESSURE_MEASUREMENT
```

In addition, to enable the cluster as a client or server, it is also necessary to add one of the following lines to the same file:

```
#define PRESSURE_MEASUREMENT_SERVER
#define PRESSURE_MEASUREMENT_CLIENT
```

The Pressure Measurement cluster contains macros that may be optionally specified at compile-time by adding one or more of the following lines to the **zcl_options.h** file.

Optional Attributes Add this line to enable the optional Tolerance attribute:

```
#define CLD_PRESSUREMEAS_ATTR_TOLERANCE
```

Global Attributes Add this line to enable the optional Attribute Reporting Status attribute:

```
#define CLD_PRESSUREMEAS_ATTR_ID_ATTRIBUTE_REPORTING_STATUS
```

Add this line to define the value (n) of the Cluster Revision attribute:

```
#define CLD_PRESSUREMEAS_CLUSTER_REVISION <n>
```

The default value is 1, which corresponds to the revision of the cluster in the ZCL r6 specification (see Section 2.4).

Parent topic:*Pressure Measurement Cluster*

Flow Measurement Cluster This chapter outlines the Flow Measurement cluster, which provides an interface for configuring and obtaining flow measurements for a fluid (liquid or gas).

The Flow Measurement cluster has a Cluster ID of 0x0404.

Overview The Flow Measurement cluster provides an interface for configuring and querying devices that perform flow measurements on a fluid (for example, water).

- The server is located on the device which makes the flow measurements
- The client is located on another device and queries the server for measurements

The cluster is enabled by defining CLD_FLOW_MEASUREMENT in the **zcl_options.h** file. Further compile-time options for the Flow Measurement cluster are detailed in Section 27.9.

Parent topic:*Flow Measurement Cluster*

Cluster structure and attributes The structure definition for the Flow Measurement cluster (server) is:

```
typedef struct
{
#ifdef FLOW_MEASUREMENT_SERVER
 zint16  i16MeasuredValue;
 zint16  i16MinMeasuredValue;
 zint16  i16MaxMeasuredValue;
#ifdef CLD_FLOWMEAS_ATTR_TOLERANCE
  zuint16 u16Tolerance;
#endif
#ifdef CLD_FLOWMEAS_ATTR_ATTRIBUTE_REPORTING_STATUS
  zenum8  u8AttributeReportingStatus;
#endif
#endif
 zuint16  u16ClusterRevision;
} tsCLD_FlowMeasurement;
```

where:

'Flow Measurement Information' Attribute Set

- i16MeasuredValue is a mandatory attribute corresponding to 10 times the measured flow, in units of cubic metres per hour (m3/h). The range of possible values is 0x0000 (0 m3/h) to 0xFFFE (representing 6553.4 m3/h). The value 0xFFFF is used to indicate that the measurement was invalid. In practice, the stored value is limited within the range i16MinMeasuredValue to i16MaxMeasuredValue (see below).
- i16MinMeasuredValue is a mandatory attribute representing a lower limit on the value that can be stored in i16MeasuredValue. It is a value in the range 0x0000 to 0x7FFD and, it must be less than the value of the attribute i16MaxMeasuredValue.
- i16MaxMeasuredValue is a mandatory attribute representing an upper limit on the value that can be stored in i16MeasuredValue. It is a value in the range 0x0000 to 0x7FFE, and it must be greater than the value of the attribute i16MinMeasuredValue.
- u16Tolerance is an optional attribute representing the maximum error associated with the measurement stored in i16MeasuredValue. Thus, the true value of the flow is within the range represented by i16MeasuredValue ± u16Tolerance.

Global Attributes

- u8AttributeReportingStatus is an optional attribute that should be enabled when attribute reporting is used for the cluster (see Section 2.3.5). The value of this attribute indicates whether there are attribute reports still pending (0x00) or the attribute reports are complete (0x01) - all other values are reserved. This attribute is also described in Section 2.4.
- u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specification on which this cluster instance is based. The cluster specification in the ZCL r6 corresponds to a cluster revision of 1. The value is incremented by one for each subsequent revision of the cluster specification. This attribute is also described in Section 2.4.

Parent topic:*Flow Measurement Cluster*

Initialization and Operation The Flow Measurement cluster must be initialized on both the cluster server and client. Initialization can be done using the **eCLD_FlowMeasurementCreateFlowMeasurement()** function, which creates an instance of the Flow Measurement cluster on a local endpoint.

Once the cluster has been initialized, the application on the server should maintain the cluster attributes (see Section 27.2) with the flow measurements made by the local device. The application on a client can remotely read these measured values using the ZCL 'Read Attribute' functions, as described in Section 2.3.2.

Parent topic:*Flow Measurement Cluster*

Flow Measurement Events There are no events specific to the Flow Measurement cluster.

Parent topic:*Flow Measurement Cluster*

Functions The following Flow Measurement cluster function is provided:

eCLD_FlowMeasurementCreateFlowMeasurement

eCLD_FlowMeasurementCreateFlowMeasurement

```
teZCL_Status eCLD_FlowMeasurementCreateFlowMeasurement(
    tsZCL_ClusterInstance *psClusterInstance,
    bool_t bIsServer,
    tsZCL_ClusterDefinition *psClusterDefinition,
    void *pvEndPointSharedStructPtr,
    uint8 *pu8AttributeControlBits);
```

Description This function creates an instance of the Flow Measurement cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function creates a Flow Measurement cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions. For more details of creating cluster instances on custom endpoints, refer to *Appendix D.*

Note: This function must not be called for an endpoint on which a standard ZigBee device is used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function from those described in the *ZigBee Devices User Guide (JNUG3131)*.

When used, this function must be called after the stack has been started and after the ZCL has been initialized.

The function requires an array to be declared for internal use, which contains one element (of type **uint8**) for each attribute of the cluster. The array length is automatically adjusted by the compiler using the following declaration:

```
uint8 au8FlowMeasurementAttributeControlBits
    [(sizeof(asCLD_FlowMeasurementClusterAttributeDefinitions) /
    sizeof(tsZCL_AttributeDefinition))];
```

Parameters

- *psClusterInstance*: Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initializing individual structure fields.

- *bIsServer*: Type of cluster instance (server or client) to be created:
  - TRUE - server
  - FALSE - client
- *psClusterDefinition*: Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the Flow Measurement cluster. This parameter can refer to a pre-filled structure called sCLD_``FlowM``easurement which is provided in the **FlowMeasurement.h** file.
- *pvEndPointSharedStructPtr*: Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_``FlowM``easurement, which defines the attributes of Flow Measurement cluster. The function initializes the attributes with default values.
- *pu8AttributeControlBits*: Pointer to an array of **uint8** values, with one element for each attribute in the cluster (see above). For a cluster client, set this pointer to NULL.

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

Parent topic:*Flow Measurement Cluster*

Return codes The Flow Measurement cluster function uses the ZCL return codes defined in Section7.2.

Parent topic:*Flow Measurement Cluster*

Enumerations

'Attribute ID' Enumerations The following structure contains the enumerations used to identify the attributes of the Flow Measurement cluster.

```
typedef enum
{
    E_CLD_FLOWMEAS_ATTR_ID_MEASURED_VALUE  = 0x0000,
    E_CLD_FLOWMEAS_ATTR_ID_MIN_MEASURED_VALUE,
    E_CLD_FLOWMEAS_ATTR_ID_MAX_MEASURED_VALUE,
    E_CLD_FLOWMEAS_ATTR_ID_TOLERANCE,
} teCLD_FlowMeasurement_AttributeID;
```

Parent topic: Enumerations

Parent topic:*Flow Measurement Cluster*

Structures There are no structures specific to the Flow Measurement cluster.

Parent topic:*Flow Measurement Cluster*

Compile-time Options This section describes the compile-time options that may be enabled in the **zcl_options.h** file of an application that uses the Flow Measurement cluster.

To enable the Flow Measurement cluster in the code to be built, it is necessary to add the following line to the file:

```
#define CLD_FLOW_MEASUREMENT
```

In addition, to enable the cluster as a client or server, it is also necessary to add one of the following lines to the same file:

```
#define FLOW_MEASUREMENT_SERVER
#define FLOW_MEASUREMENT_CLIENT
```

The Flow Measurement cluster contains macros that may be optionally specified at compile-time by adding one or more of the following lines to the **zcl_options.h** file.

Optional Attributes Add this line to enable the optional Tolerance attribute:

```
#define CLD_FLOWMEAS_ATTR_TOLERANCE
```

Global Attributes Add this line to enable the optional Attribute Reporting Status attribute:

```
#define CLD_FLOWMEAS_ATTR_ID_ATTRIBUTE_REPORTING_STATUS
```

Add this line to define the value (n) of the Cluster Revision attribute:

```
#define CLD_FLOWMEAS_CLUSTER_REVISION <n>
```

The default value is 1, which corresponds to the revision of the cluster in the ZCL r6 specification (see Section 2.4).

Parent topic:*Flow Measurement Cluster*

Relative Humidity Measurement Cluster This chapter describes the Relative Humidity Measurement cluster which describes how to configure and report relative humidity measurement.

The Relative Humidity Measurement cluster has a Cluster ID of 0x0405.

Overview The Relative Humidity Measurement cluster provides an interface to a humidity measuring device, allowing the configuration of relative humidity measuring and the reporting of measurements.

To use the functionality of this cluster, you must include the file **RelativeHumidityMeasurement.h** in your application and enable the cluster by defining CLD_RELATIVE_HUMIDITY_MEASUREMENT in the **zcl_options.h** file.

A Relative Humidity Measurement cluster instance can act as a client or a server. The inclusion of the client or server software must be pre-defined in the application's compile-time options (in addition, if the cluster is to reside on a custom endpoint then the role of client or server must also be specified when creating the cluster instance).

The compile-time options for the Relative Humidity Measurement cluster are fully detailed in Section 28.6.

Parent topic:*Relative Humidity Measurement Cluster*

RH Measurement Structure and Attributes The structure definition for the Relative Humidity Measurement cluster (server) is:

```
typedef struct
{
    zuint16     u16MeasuredValue;
    zuint16     u16MinMeasuredValue;
    zuint16     u16MaxMeasuredValue;
#ifdef E_CLD_RHMEAS_ATTR_TOLERANCE
    zuint16     u16Tolerance;
#endif
} tsCLD_RelativeHumidityMeasurement;
```

where:

- u1``6MeasuredValue is a mandatory attribute representing the measured relatively humidity as a percentage in steps of 0.01%, as follows:
  - u1``6MeasuredValue = 100 x relative humidity percentage
  - So, for example, 0x197C represents a relative humidity measurement of 65.24%. The possible values are used as follows:
  - 0x0000 to 0x2710 represent relative humidities from 0% to 100%
  - 0x2711 to 0xFFFE are unused values
  - 0xFFFF indicates an invalid measurement
  - This attribute is updated continuously as measurements are made.
- u16MinMeasuredValue is a mandatory attribute specifying the value of the attribute u16MeasuredValue which corresponds to the minimum possible relative humidity that can be measured. Its value must be less than that of the attribute u16MaxMeasuredValue (below). The special value 0xFFFF is used to indicate that the minimum is not defined.
- u16MaxMeasuredValue is a mandatory attribute specifying the value of the attribute u16MeasuredValue which corresponds to the maximum possible relative humidity that can be measured. Its value must be greater than that of the attribute u16MinMeasuredValue (above). The special value 0xFFFF is used to indicate that the maximum is not defined.
- u16Tolerance is an optional attribute which indicates the magnitude of the maximum possible error in the value of the attribute u16MeasuredValue. The true value will be in the range (u16MeasuredValue – u16Tolerance) to (u16MeasuredValue + u16Tolerance).
- u8AttributeReportingStatus is an optional attribute that should be enabled when attribute reporting is used for the cluster (see Section 2.3.5). The value of this attribute indicates whether there are attribute reports still pending (0x00) or the attribute reports are complete (0x01) - all other values are reserved. This attribute is also described in Section 2.4.
- u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specification on which this cluster instance is based. The cluster specification in the ZCL r6 corresponds to a cluster revision of 1. The value is incremented by one for each subsequent revision of the cluster specification. This attribute is also described in Section 2.4.

Parent topic:*Relative Humidity Measurement Cluster*

Attributes for Default Reporting The following attributes of the Relative Humidity Measurement cluster can be selected for default reporting:

```
u16MeasuredValue
u16Tolerance
```

Attribute reporting (including default reporting) is described in *Appendix B.* Enabling reports for these attributes is described in Appendix B.3.6.

Parent topic:*Relative Humidity Measurement Cluster*

Functions The following Relative Humidity Measurement cluster function is provided in the NXP implementation of the ZCL:

- eCLD_RelativeHumidityMeasurementCreateRelativeHumidityMeasurement

eCLD_RelativeHumidityMeasurementCreateRelativeHumidityMeasurement

```
teZCL_Status eCLD_RelativeHumidityMeasurementCreateRelativeHumidityMeasurement(
    tsZCL_ClusterInstance *psClusterInstance,
    bool_t bIsServer,
    tsZCL_ClusterDefinition *psClusterDefinition,
    void *pvEndPointSharedStructPtr,
    uint8 *pu8AttributeControlBits);
```

Description This function creates an instance of the Relative Humidity Measurement cluster on an endpoint. The cluster instance is created on the endpoint associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function creates a Relative Humidity Measurement cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions.

Note: This function must not be called for an endpoint on which a standard ZigBee device is used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function.

When used, this function must be called after the stack has been started and after the ZCL has been initialized.

The function requires an array to be declared for internal use, which contains one element (of type **uint8**) for each attribute of the cluster. The array length is automatically adjusted by the compiler using the following declaration:

```
uint8 au8RelativeHumidityMeasurementAttributeControlBits
  [(sizeof(asCLD_RelativeHumidityMeasurementClusterAttributeDefinitions) /
  sizeof(tsZCL_AttributeDefinition))];
```

Parameters

- *psClusterInstance*: Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initializing individual structure fields.
- *bIsServer*: Type of cluster instance (server or client) to be created:
  - TRUE - server

  - FALSE - client

- *psClusterDefinition*: Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the Relative Humidity Measurement cluster. This parameter can refer to a pre-filled structure called sCLD_RelativeHumidityMeasurement which is provided in the **RelativeHumidityMeasurement.h** file.
- *pvEndPointSharedStructPtr*: Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_RelativeHumidityMeasurement which defines the attributes of Relative Humidity Measurement cluster. The function initializes the attributes with default values.
- *pu8AttributeControlBits*: Pointer to an array of **uint8** values, with one element for each attribute in the cluster (see above). For a cluster client, set this pointer to NULL.

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

Parent topic:*Relative Humidity Measurement Cluster*

Enumerations

teCLD_RHM_ClusterID The following structure contains the enumerations used to identify the attributes of the Relative Humidity Measurement cluster.

```
typedef enum
{
    E_CLD_RHMEAS_ATTR_ID_MEASURED_VALUE = 0x0000,   /* Mandatory */
    E_CLD_RHMEAS_ATTR_ID_MIN_MEASURED_VALUE,     /* Mandatory */
    E_CLD_RHMEAS_ATTR_ID_MAX_MEASURED_VALUE,     /* Mandatory */
    E_CLD_RHMEAS_ATTR_ID_TOLERANCE,
} teCLD_RHM_ClusterID;
```

Parent topic: Enumerations

Parent topic:*Relative Humidity Measurement Cluster*

Compile-time Options To enable the Relative Humidity Measurement cluster in the code to be built, it is necessary to add the following to the **zcl_options.h** file:

```
#define CLD_RELATIVE_HUMIDITY_MEASUREMENT
```

In addition, to include the software for a cluster client or server, it is necessary to add one of the following to the same file:

```
#define RELATIVE_HUMIDITY_MEASUREMENT_CLIENT
#define RELATIVE_HUMIDITY_MEASUREMENT_SERVER
```

Optional Attribute Add this line to enable the optional Tolerance attribute:

```
#define CLD_RHMEAS_ATTR_TOLERANCE
```

Global Attributes Add this line to enable the optional Attribute Reporting Status attribute:

```
#define CLD_RHMEAS_ATTR_ID_ATTRIBUTE_REPORTING_STATUS
```

Add this line to define the value (n) of the Cluster Revision attribute:

```
#define CLD_RHMEAS_CLUSTER_REVISION <n>
```

The default value is 1, which corresponds to the revision of the cluster in the ZCL r6 specification (see Section 2.4).

Parent topic:*Relative Humidity Measurement Cluster*

Occupancy Sensing Cluster This chapter describes the Occupancy Sensing cluster which provides an interface to an occupancy sensor.

The Occupancy Sensing cluster has a Cluster ID of 0x0406.

Overview The Occupancy Sensing cluster provides an interface to an occupany sensor, allowing the configuration of sensing and the reporting of status.

To use the functionality of this cluster, you must include the file **OccupancySensing.h** in your application and enable the cluster by defining CLD_OCCUPANCY_SENSING in the **zcl_options.h** file.

An Occupancy Sensing cluster instance can act as a client or a server. The inclusion of the client or server software must be pre-defined in the application's compile-time options (in addition, if the cluster is to reside on a custom endpoint then the role of client or server must also be specified when creating the cluster instance).

The compile-time options for the Occupancy Sensing cluster are fully detailed in Section 29.6.

The information that can potentially be stored in this cluster is organised into the following attribute sets:

- Occupancy sensor information
- PIR configuration
- Ultrasonic configuration

This cluster has no associated events. The status of an occupancy sensor can be obtained by reading the 'occupancy' attribute (see Section 29.2) which is automatically maintained by the cluster server. The cluster attributes can be accessed using the general attribute read/write functions, as described in Section 2.3.

Parent topic:*Occupancy Sensing Cluster*

Occupancy Sensing Structure and Attributes The structure definition for the Occupancy Sensing cluster is:

```
typedef struct
{
#ifdef OCCUPANCY_SENSING_SERVER
    zbmap8    u8Occupancy;
    zenum8    eOccupancySensorType;
#ifdef CLD_OS_ATTR_PIR_OCCUPIED_TO_UNOCCUPIED_DELAY
    zuint16 u16PIROccupiedToUnoccupiedDelay;
#endif
#ifdef CLD_OS_ATTR_PIR_UNOCCUPIED_TO_OCCUPIED_DELAY
    zuint8  u8PIRUnoccupiedToOccupiedDelay;
#endif
#ifdef CLD_OS_ATTR_PIR_UNOCCUPIED_TO_OCCUPIED_THRESHOLD
    zuint8  u8PIRUnoccupiedToOccupiedThreshold;
#endif
#ifdef CLD_OS_ATTR_ULTRASONIC_OCCUPIED_TO_UNOCCUPIED_DELAY
    zuint16 u16UltrasonicOccupiedToUnoccupiedDelay;
#endif
#ifdef CLD_OS_ATTR_ULTRASONIC_UNOCCUPIED_TO_OCCUPIED_DELAY
    zuint8  u8UltrasonicUnoccupiedToOccupiedDelay;
#endif
#ifdef CLD_OS_ATTR_ULTRASONIC_UNOCCUPIED_TO_OCCUPIED_THRESHOLD
    zuint8      u8UltrasonicUnoccupiedToOccupiedThreshold;
#endif
#ifdef CLD_OS_ATTR_ATTRIBUTE_REPORTING_STATUS
    zenum8  u8AttributeReportingStatus;
#endif
#endif
    zuint16 u16ClusterRevision;
} tsCLD_OccupancySensing;
```

where:

'Occupancy Sensor Information' Attribute Set

- u8Occupancy is a mandatory attribute indicating the sensed occupancy in a bitmap in which bit 0 is used as follows (and all other bits are reserved):
  - bit 0 = 1 : occupied
  - bit 0 = 0 : unoccupied
- eOccupancySensorType is a mandatory attribute indicating the type of occupancy sensor, as follows:
  - 0x00 : PIR
  - 0x01 : Ultrasonic
  - 0x02 : PIR and ultrasonic

'PIR Configuration' Attribute Set

- u16P``IROccupiedToUnoccupiedDelay is an optional attribute for a PIR detector representing the time delay, in seconds, between the last detected movement and the sensor changing its occupancy state from 'occupied' to 'unoccupied'
- u8PIRUnoccupiedToOccupiedDelay is an optional attribute for a PIR detector representing the time delay, in seconds, between the detection of movement and the sensor changing its occupancy state from 'unoccupied' to 'occupied'. The interpretation of this attribute changes when it is used in conjunction with the corresponding threshold attribute (see below)

- u8PIRUnoccupiedToOccupiedThreshold is an optional threshold attribute that can be used in conjunction with the delay attribute u8PIRUnoccupiedToOccupiedDelay to allow for false positive detections. Use of this threshold attribute changes the interpretation of the delay attribute. The threshold represents the minimum number of detections required within the delay-period before the sensor will change its occupancy state from 'unoccupied' to 'occupied'. The minimum valid threshold value is 1

'Ultrasonic Configuration' Attribute Set

- u16U``ltrasonicOccupiedToUnoccupiedDelay is an optional attribute for an Ultrasonic detector representing the time delay, in seconds, between the last detected movement and the sensor changing its occupancy state from 'occupied' to 'unoccupied'
- u8UltrasonicUnoccupiedToOccupiedDelay is an optional attribute representing the time delay, in seconds, between the detection of movement and the sensor changing its occupancy state from 'unoccupied' to 'occupied'. The interpretation of this attribute changes when it is used in conjunction with the corresponding threshold attribute (see below)
- u8UltrasonicUnoccupiedToOccupiedThreshold is an optional threshold attribute that can be used in conjunction with the delay attribute u8UltrasonicUnoccupiedToOccupiedDelay to allow for false positive detections. Use of this threshold attribute changes the interpretation of the delay attribute. The threshold represents the minimum number of detections required within the delay-period before the sensor will change its occupancy state from 'unoccupied' to 'occupied'. The minimum valid threshold value is 1

Note: The 'Occupied To Unoccupied' and 'Unoccupied To Occupied' attributes can be used to reduce sensor 'chatter' when an occupancy sensor is deployed in an area in which the occupation frequently changes

Note: (e.g. in a corridor).

Global Attributes

- u8AttributeReportingStatus is an optional attribute that should be enabled when attribute reporting is used for the cluster (see Section 2.3.5). The value of this attribute indicates whether there are attribute reports still pending (0x00) or the attribute reports are complete (0x01) - all other values are reserved. This attribute is also described in Section 2.4.

u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specification on which this cluster instance is based. The cluster specification in the ZCL r6 corresponds to a cluster revision of 1. The value is incremented by one for each subsequent revision of the cluster specification. This attribute is also described in [Section 2.4](../../ZCL_fundamentals/topics/global_attributes.md#id_8f80e769-8ccd-4b4f-8609-579f4457d527).

Parent topic:*Occupancy Sensing Cluster*

Attributes for Default Reporting The following attribute of the Occupancy Sensing cluster can be selected for default reporting:

u8Occupancy

Attribute reporting (including default reporting) is described in *Appendix B.* Enabling reports for this attribute is described in Appendix B.3.6.

Parent topic:*Occupancy Sensing Cluster*

Functions The following Occupancy Sensing cluster function is provided in the NXP implementation of the ZCL:

- eCLD_OccupancySensingCreateOccupancySensing

The cluster attributes can be accessed using the general attribute read/write functions, as described in Section 2.3. The state of the occupancy sensor can be obtained by reading the u8Occupancy attribute in the tsCLD_OccupancySensing structure on the cluster server (see Section 29.2).

eCLD_OccupancySensingCreateOccupancySensing

```
teZCL_Status eCLD_OccupancySensingCreateOccupancySensing(
    tsZCL_ClusterInstance *psClusterInstance,
    bool_t bIsServer,
    tsZCL_ClusterDefinition *psClusterDefinition,
    void *pvEndPointSharedStructPtr,
    uint8 *pu8AttributeControlBits);
```

Description This function creates an instance of the Occupancy Sensing cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function creates an Occupancy Sensing cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions.

Note: This function must not be called for an endpoint on which a standard ZigBee device is used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function.

When used, this function must be called after the stack has been started and after the ZCL has been initialized.

The function requires an array to be declared for internal use, which contains one element (of type **uint8**) for each attribute of the cluster. The array length should therefore equate to the total number of attributes supported by the Occupancy Sensing cluster. The function initializes the array elements to zero.

Parameters

- *psClusterInstance*: Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initialising individual structure fields.
- *bIsServer* : Type of cluster instance (server or client) to be created:
  - TRUE - server
  - FALSE - client
- *psClusterDefinition*: Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the Occupancy Sensing cluster. This parameter can refer to a pre-filled structure called sCLD_OccupancySensing which is provided in the **OccupancySensing.h** file.
- *pvEndPointSharedStructPtr*: Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_OccupancySensing which

defines the attributes of Occupancy Sensing cluster. The function initializes the attributes with default values.

- *pu8AttributeControlBits*: Pointer to an array of **uint8** values, with one element for each attribute in the cluster (see above).

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

Parent topic:*Occupancy Sensing Cluster*

Enumerations

teCLD_OS_ClusterID The following structure contains the enumeration used to identify the attributes of the Occupancy Sensing cluster.

```
typedef enum
{
  E_CLD_OS_ATTR_ID_OCCUPANCY = 0x0000,  /* Mandatory */
  E_CLD_OS_ATTR_ID_OCCUPANCY_SENSOR_TYPE,  /* Mandatory */
  E_CLD_OS_ATTR_ID_PIR_OCCUPIED_TO_UNOCCUPIED_DELAY = 0x0010,
  E_CLD_OS_ATTR_ID_PIR_UNOCCUPIED_TO_OCCUPIED_DELAY,
  E_CLD_OS_ATTR_ID_PIR_UNOCCUPIED_TO_OCCUPIED_THRESHOLD,
  E_CLD_OS_ATTR_ID_ULTRASONIC_OCCUPIED_TO_UNOCCUPIED_DELAY = 0x0020,
  E_CLD_OS_ATTR_ID_ULTRASONIC_UNOCCUPIED_TO_OCCUPIED_DELAY,
  E_CLD_OS_ATTR_ID_ULTRASONIC_UNOCCUPIED_TO_OCCUPIED_THRESHOLD
} teCLD_OS_ClusterID;
```

Parent topic: Enumerations

Parent topic:*Occupancy Sensing Cluster*

Compile-time options To enable the Occupancy Sensing cluster in the code to be built, it is necessary to add the following to the **zcl_options.h** file:

```
#define CLD_OCCUPANCY_SENSING
```

In addition, to include the software for a cluster client or server or both, it is necessary to add one of the following to the same file:

```
#define OCCUPANCY_SENSING_CLIENT
#define OCCUPANCY_SENSING_SERVER
```

Optional Attributes Add this line to enable the optional PIR Occupied To Unoccupied Delay attribute:

```
#define CLD_OS_ATTR_PIR_OCCUPIED_TO_UNOCCUPIED_DELAY
```

Add this line to enable the optional PIR Unoccupied To Occupied Delay attribute:

```
#define CLD_OS_ATTR_PIR_UNOCCUPIED_TO_OCCUPIED_DELAY
```

Add this line to enable the optional PIR Unoccupied To Occupied Threshold attribute:

```
#define CLD_OS_ATTR_PIR_UNOCCUPIED_TO_OCCUPIED_THRESHOLD
```

Add this line to enable the optional Ultrasonic Occupied To Unoccupied Delay attribute:

```
#define CLD_OS_ATTR_ULTRASONIC_OCCUPIED_TO_UNOCCUPIED_DELAY
```

Add this line to enable the optional Ultrasonic Unoccupied To Occupied Delay attribute:

```
#define CLD_OS_ATTR_ULTRASONIC_UNOCCUPIED_TO_OCCUPIED_DELAY
```

Add this line to enable the Ultrasonic PIR Unoccupied To Occupied Threshold attribute:

```
#define CLD_OS_ATTR_ULTRASONIC_UNOCCUPIED_TO_OCCUPIED_THRESHOLD
```

Global Attributes Add this line to enable the optional Attribute Reporting Status attribute:

```
#define CLD_OS_ATTR_ID_ATTRIBUTE_REPORTING_STATUS
```

Add this line to define the value (n) of the Cluster Revision attribute:

```
#define CLD_OS_CLUSTER_REVISION <n>
```

The default value is 1, which corresponds to the revision of the cluster in the ZCL r6 specification (see Section 2.4).

Parent topic:*Occupancy Sensing Cluster*

Electrical Measurement Cluster This chapter outlines the Electrical Measurement cluster, which provides an interface for obtaining electrical measurements from a device.

The Electrical Measurement cluster has a Cluster ID of 0x0B04.

Overview The Electrical Measurement cluster provides an interface for querying devices for electrical measurements.

- The server is located on the device which makes the electrical measurements
- The client is located on another device and queries the server for measurements

Separate instances of the Electrical Measurement cluster server can be implemented across multiple endpoints within the same physical unit - that is, one server instance per endpoint. An example is a power extension unit containing multiple outlets, where each power outlet allows electrical measurements to be made on the supplied power (e.g. AC RMS voltage and current).

The cluster is enabled by defining CLD_ELECTRICAL_MEASUREMENT in the **zcl_options.h** file. Further compile-time options for the Electrical Measurement cluster are detailed in Section 30.9.

The information that can potentially be stored in this cluster is organised into the following attribute sets:

- Basic Information
- DC Measurement
- DC Formatting
- AC (Non-phase Specific) Measurements
- AC (Non-phase Specific) Formatting
- AC (Single Phase or Phase A) Measurements
- AC Formatting
- DC Manufacturer Threshold Alarms
- AC Manufacturer Threshold Alarms
- AC Phase B Measurements
- AC Phase C Measurements

Note that not all of the above attribute sets are currently implemented in the NXP software and not all attributes within a supported attribute set are implemented (see Section 30.2 for the supported attribute sets and attributes).

Parent topic:*Electrical Measurement Cluster*

Cluster structure and attributes The structure definition for the Electrical Measurement cluster (server) is:

```
typedef struct
{
#ifdef ELECTRICAL_MEASUREMENT_SERVER
zbmap32 u32MeasurementType;
#ifdef CLD_ELECTMEAS_ATTR_AC_FREQUENCY
zuint16 u16ACFrequency;
#endif
#ifdef CLD_ELECTMEAS_ATTR_RMS_VOLTAGE

#ifdef CLD_ELECTMEAS_ATTR_MAN_SPEC_DIVISOR
zuint16 u16ManSpecDivisor;
#endif
#endif
zuint16 u16ClusterRevision;
}tsCLD_ElectricalMeasurement;
```

where:

'Basic Information' Attribute Set u32MeasurementType is a mandatory attribute which is a bitmap indicating the types of electrical measurement that can be performed by the deivice on which the cluster server resides. The bitmap is detailed below(a bit is set to '1' if the corresponding measurement type is supported, or to '0' otherwise):

Bits	Measurement Type
0	Active measurement (AC)
1	Reactive measurement (AC)
2	Apparent measurement (AC)
3	Phase A measurement
4	Phase B measurement
5	Phase C measurement
6	DC measurement
7	Harmonics measurement
8	Power quality measurement
9-31	Reserved

'AC (Non-phase Specific) Measurements' Attribute Set

- u16ACFrequency is an optional attribute containing the most recent measurement of the AC frequency, in Hertz(Hz). The special value 0xFFFF is used to indicate that the frequency cannot be measured.

'AC (Single Phase or Phase A) Measurements' Attribute Set Note that the attributes u16RMSVoltage, u16RMSCurrent and i16ActivePower must be enabled in conjunction with the corresponding multiplier/divisor pair in the 'AC Formatting' attribute set.

- u16RMSVoltage is an optional attribute containing the most recent measurement of the Root Mean Square (RMS) voltage, in Volts. The special value 0xFFFF is used to indicate that the RMS voltage cannot be measured. Note that the 'AC Formatting' attributes u16ACVoltageMultiplier and u16ACVoltageDivisor must be implemented with this attribute.
- u16RMSCurrent is an optional attribute containing the most recent measurement of the Root Mean Square (RMS) current, in Amps. The special value 0xFFFF is used to indicate that the RMS current cannot be measured. Note that the 'AC Formatting' attributes u16ACCurrentMultiplier and u16ACCurrentDivisor must be implemented with this attribute.
- i16ActivePower is an optional attribute containing the present single-phase or Phase-A demand for active power, in Watts (W). A positive value represents active power delivered to the premises and a negative value represents active power received from the premises. Note that the 'AC Formatting' attributes u16ACPowerMultiplier and u16ACPowerDivisor must be implemented with this attribute.
- i16ReactivePower is an optional attribute containing the present single-phase or Phase-A demand for reactive power, in Volts-Amps-reactive (VAr). A positive value represents reactive power delivered to the premises and a negative value represents reactive power received from the premises.
- u16ApparentPower is an optional attribute containing the present single-phase or Phase-A demand for apparent power, in Volts-Amps (VA). This value is the positive square-root of i16ActivePower squared plus i16ReactivePower squared.
- i8PowerFactor is an optional attribute containing the single-phase or Phase-A power factor ratio represented as a multiple of 0.01(e.g. the attribute value 0x0C represents a ratio of 0.12).

'AC Formatting' Attribute Set The following attributes come in multiplier/divisor pairs, where each pair corresponds to an attribute of the 'AC (Single Phase or Phase A) Measurements' attribute set and must only be enabled if the corresponding attribute is enabled.

- u16ACVoltageMultiplier is an optional attribute containing the multiplication factor to be applied to the value of the u16RMSVoltage attribute (above). This multiplication factor must be used in conjunction with the u16ACVoltageDivisor division factor. The value 0x0000 is not valid.
- u16ACVoltageDivisor is an optional attribute containing the division factor to be applied to the value of the u16RMSVoltage attribute (above). This division factor must be used in conjunction with the u16ACVoltageMultiplier multiplication factor. The value 0x0000 is not valid.
- u16ACCurrentMultiplier is an optional attribute containing the multiplication factor to be applied to the value of the u16RMSCurrent attribute (above). This multiplication factor must be used in conjunction with the u16ACCurrentDivisor division factor. The value 0x0000 is not valid.
- u16ACCurrentDivisor is an optional attribute containing the division factor to be applied to the value of the u16RMSCurrent attribute (above). This division factor must be used in conjunction with the u16ACCurrentMultiplier multiplication factor. The value 0x0000 is not valid.
- u16ACPowerMultiplier is an optional attribute containing the multiplication factor to be applied to the value of the i16ActivePower attribute (above). This multiplication factor must be used in conjunction with the u16ACPowerDivisor division factor. The value 0x0000 is not valid.
- u16ACPowerDivisor is an optional attribute containing the division factor to be applied to the value of the i16ActivePower attribute (above). This division factor must be used in conjunction with the u16ACPowerMultiplier multiplication factor. The value 0x0000 is not valid.

Manufacturer-specific Attributes

- u32ManSpecificApparentPower is an optional manufacturer-defined attribute containing the demand for apparent power.
- u32NonActivePower is an optional manufacturer-defined attribute containing the demand for non-active power.
- i32FundamentalReactivePower is an optional manufacturer-defined attribute containing the demand for fundamental reactive power.
- u32FundamentalApparentPower is an optional manufacturer-defined attribute containing the demand for fundamental apparent power.
- u16FundamentalPowerFactor is an optional manufacturer-defined attribute representing the power factor of a fundamental power system u32NonFundamentalApparentPower is an optional manufacturer-defined attribute representing the power factor of a non-fundamental (harmonic) power system.
- u32TotalHarmonicDistortion is an optional manufacturer-defined attribute representing the total harmonic distortion present in the delivered power signal.
- u32VBias is an optional manufacturer-defined attribute representing the bias voltage.
- u16ManSpecDivisor is an optional manufacturer-defined attribute representing a power divisor.

Global Attributes

- u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specification on which this cluster instance is based. The cluster specification in the ZCL r6 corresponds to a cluster revision of 1. The value is incremented by one for each subsequent revision of the cluster specification. This attributeis also described in Section2.4.

Parent topic:*Electrical Measurement Cluster*

Initialisation and Operation The Electrical Measurement cluster must be initialised on both the cluster server and client. This can be done using the function **eCLD_ElectricalMeasurementCreateElectricalMeasurement()**, which creates an instance of the Electrical Measurement cluster on a local endpoint.

Once the cluster has been initialized, the application on the server should maintain the cluster attributes (see Section 30.2) with the electrical measurements made by the local device. The application on a client can remotely read these measured values using the ZCL 'Read Attribute' functions, as described in Section 2.3.2.

Parent topic:*Electrical Measurement Cluster*

Electrical Measurement Events There are no events specific to the Electrical Measurement cluster.

Parent topic:*Electrical Measurement Cluster*

Functions The following Electrical Measurement cluster function is provided:

- **Function Page**
- eCLD_ElectricalMeasurementCreateElectricalMeasurement 618

eCLD_ElectricalMeasurementCreateElectricalMeasurement

```
teZCL_Status eCLD_ElectricalMeasurementCreateElectricalMeasurement(
    tsZCL_ClusterInstance *psClusterInstance,
    bool_t bIsServer,
    tsZCL_ClusterDefinition *psClusterDefinition,
    void *pvEndPointSharedStructPtr,
    uint8 *pu8AttributeControlBits);
```

Description This function creates an instance of the Electrical Measurement cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function will create an Electrical Measurement cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions. For more details of creating cluster instances on custom endpoints, refer to *Appendix D.*

Note: This function must not be called for an endpoint on which a standard ZigBee device is used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function from those described in the *ZigBee Devices User Guide (JNUG3131).*

When used, this function must be called after the stack has been started and after the ZCL has been initialized.

The function requires an array to be declared for internal use, which contains one element (of type **uint8**) for each attribute of the cluster. The array length is automatically adjusted by the compiler using the following declaration:

```
uint8 au8ElectricalMeasurementAttributeControlBits
[(sizeof(asCLD_ElectricalMeasurementClusterAttributeDefinitions) / sizeof(tsZCL_AttributeDefinition))];
```

Parameters

- *psClusterInstance* Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initialising individual structure fields.
- *bIsServer* Type of cluster instance (server or client) to be created:
- TRUE - server
- FALSE - client
- *psClusterDefinition* Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the Electrical Measurement cluster. This parameter can refer to a pre-filled structure called sCLD_``ElectricalMeasurement which is provided in the **ElectricalMeasurement.h** file.
- *pvEndPointSharedStructPtr* Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_``ElectricalMeasurement which defines the attributes of Electrical Measurement cluster. The function initializes the attributes with default values.
- *pu8AttributeControlBits* Pointer to an array of **uint8** values, with one element for each attribute in the cluster (see above). For a cluster client, set this pointer to NULL.

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

Parent topic:*Electrical Measurement Cluster*

Return codes The Electrical Measurement cluster function uses the ZCL return codes, listed in Section 7.2.

Parent topic:*Electrical Measurement Cluster*

Enumerations

'Attribute ID' Enumerations The following structure contains the enumerations used to identify the attributes of the Electrical Measurement cluster.

```
typedef enum
{
    E_CLD_ELECTMEAS_ATTR_ID_MEASUREMENT_TYPE
    E_CLD_ELECTMEAS_ATTR_ID_AC_FREQUENCY
    E_CLD_ELECTMEAS_ATTR_ID_RMS_VOLTAGE                 = 0x0505,
    E_CLD_ELECTMEAS_ATTR_ID_RMS_CURRENT                 = 0x0508,
    E_CLD_ELECTMEAS_ATTR_ID_ACTIVE_POWER                = 0x050B,
    E_CLD_ELECTMEAS_ATTR_ID_REACTIVE_POWER              = 0x050E,
    E_CLD_ELECTMEAS_ATTR_ID_APPARENT_POWER              = 0x050F,
    E_CLD_ELECTMEAS_ATTR_ID_POWER_FACTOR                = 0x0510,
    E_CLD_ELECTMEAS_ATTR_ID_AC_VOLTAGE_MULTIPLIER       = 0x0600,
    E_CLD_ELECTMEAS_ATTR_ID_AC_VOLTAGE_DIVISOR          = 0x0601,
    E_CLD_ELECTMEAS_ATTR_ID_AC_CURRENT_MULTIPLIER       = 0x0602,
```

(continues on next page)

(continued from previous page)

```
    E_CLD_ELECTMEAS_ATTR_ID_AC_CURRENT_DIVISOR          = 0x0603,
    E_CLD_ELECTMEAS_ATTR_ID_AC_POWER_MULTIPLIER         = 0x0604,
    E_CLD_ELECTMEAS_ATTR_ID_AC_POWER_DIVISOR            = 0x0605,
    E_CLD_ELECTMEAS_ATTR_ID_MAN_SPEC_APPARENT_POWER     = 0xFF00,
    E_CLD_ELECTMEAS_ATTR_ID_MAN_SPEC_NON_ACTIVE_POWER,
    E_CLD_ELECTMEAS_ATTR_ID_MAN_SPEC_FNDMTL_REACTIVE_POWER,
    E_CLD_ELECTMEAS_ATTR_ID_MAN_SPEC_FNDMTL_APPARENT_POWER,
    E_CLD_ELECTMEAS_ATTR_ID_MAN_SPEC_FNDMTL_POWER_FACTOR,
    E_CLD_ELECTMEAS_ATTR_ID_MAN_SPEC_NON_FNDMTL_APPARENT_POWER,
    E_CLD_ELECTMEAS_ATTR_ID_MAN_SPEC_TOTAL_HARMONIC_DISTORTION,
    E_CLD_ELECTMEAS_ATTR_ID_MAN_SPEC_VBIAS,
    E_CLD_ELECTMEAS_ATTR_ID_MAN_SPEC_DIVISOR,
} teCLD_ElectricalMeasurement_AttributeID;
```

Parent topic: Enumerations

Parent topic:*Electrical Measurement Cluster*

Structures There are no structures specific to the Electrical Measurement cluster.

Parent topic:*Electrical Measurement Cluster*

Compile-time options This section describes the compile-time options that may be enabled in the **zcl_options.h** file of an application that uses the Electrical Measurement cluster.

To enable the Electrical Measurement cluster in the code to be built, it is necessary to add the following line to the file:

```
#define CLD_ELECTRICAL_MEASUREMENT
```

In addition, to enable the cluster as a client or server, it is also necessary to add one of the following lines to the same file:

```
#define ELECTRICAL_MEASUREMENT_SERVER
#define ELECTRICAL_MEASUREMENT_CLIENT
```

Optional Attributes The optional attributes for the Electrical Measurement cluster (see Section 30.2) are enabled by defining:

- CLD_ELECTMEAS_ATTR_AC_FREQUENCY
- CLD_ELECTMEAS_ATTR_RMS_VOLTAGE
- CLD_ELECTMEAS_ATTR_RMS_CURRENT
- CLD_ELECTMEAS_ATTR_ACTIVE_POWER
- CLD_ELECTMEAS_ATTR_REACTIVE_POWER
- CLD_ELECTMEAS_ATTR_APPARENT_POWER
- CLD_ELECTMEAS_ATTR_POWER_FACTOR
- CLD_ELECTMEAS_ATTR_AC_VOLTAGE_MULTIPLIER
- CLD_ELECTMEAS_ATTR_AC_VOLTAGE_DIVISOR
- CLD_ELECTMEAS_ATTR_AC_CURRENT_MULTIPLIER
- CLD_ELECTMEAS_ATTR_AC_CURRENT_DIVISOR

- CLD_ELECTMEAS_ATTR_AC_POWER_MULTIPLIER
- CLD_ELECTMEAS_ATTR_AC_POWER_DIVISOR
- CLD_ELECTMEAS_ATTR_MAN_SPEC_APPARENT_POWER
- CLD_ELECTMEAS_ATTR_MAN_SPEC_NON_ACTIVE_POWER
- CLD_ELECTMEAS_ATTR_MAN_SPEC_FNDMTL_REACTIVE_POWER
- CLD_ELECTMEAS_ATTR_MAN_SPEC_FNDMTL_APPARENT_POWER
- CLD_ELECTMEAS_ATTR_MAN_SPEC_FNDMTL_POWER_FACTOR
- CLD_ELECTMEAS_ATTR_MAN_SPEC_NON_FNDMTL_APPARENT_POWER
- CLD_ELECTMEAS_ATTR_MAN_SPEC_TOTAL_HARMONIC_DISTORTION
- CLD_ELECTMEAS_ATTR_MAN_SPEC_VBIAS
- CLD_ELECTMEAS_ATTR_MAN_SPEC_DIVISOR

Global Attributes Add this line to define the value (n) of the Cluster Revision attribute:

```
#define CLD_APPLIANCE_STATISTICS_CLUSTER_REVISION <n>
```

The default value is 1, which corresponds to the revision of the cluster in the ZCL r6 specification (see Section 2.4).

Parent topic:*Electrical Measurement Cluster*

Part V: Lighting Clusters

- This part comprises two chapters:
  - *Chapter 31* details the **Colour Control** cluster
  - *Chapter 32* details the **Ballast Configuration** cluster

Colour Control Cluster This chapter describes the Colour Control cluster which is defined in the ZCL.

The Colour Control cluster has a Cluster ID of 0x0300.

Overview The Colour Control cluster is used to control the colour of a light.

Note: Note 1: This cluster should normally be used with the Level Control cluster (see *Chapter 16*) and On/Off cluster (see *Chapter 14*). This is assumed to be the case in this description.

Note: Note 2: This cluster only controls the colour balance and not the overall brightness of a light. The brightness is adjusted using the Level Control cluster.

The Colour Control cluster provides the facility to specify the colour of a light in the colour space defined in the *Commission Internationale de l'Éclairage (CIE) specification (1931)*. Colour control can be performed in terms of any of the following:

- x and y values, as defined in the CIE specification
- hue and saturation
- colour temperature

To use the functionality of this cluster, you must include the file **ColourControl.h** in your application and enable the cluster by defining CLD_COLOUR_CONTROL in the **zcl_options.h** file - see Section 31.9.

It is also necessary to enable the cluster as a server or client, or as both:

- The cluster server is able to receive commands to change the colour on the local light device.
- The cluster client is able to send commands to change the colour on the remote light device.

The inclusion of the client or server software must be pre-defined in the application's compile-time options (in addition, if the cluster is to reside on a custom endpoint then the role of client or server must also be specified when creating the cluster instance).

The compile-time options for the Colour Control cluster are fully detailed in Section31.9.

The information that can potentially be stored in this cluster is organized into the following attribute sets:

- Colour Information
- Defined Primaries Information
- Additional Defined Primaries Information
- Defined Colour Point Settings
- Enhanced Colour Mode

Parent topic:*Colour Control Cluster*

Colour Control Cluster structure and attributes The structure definition for the Colour Control cluster is:

```
typedef struct
{
#ifdef COLOUR_CONTROL_SERVER
    /* Colour information attribute set */
#ifdef CLD_COLOURCONTROL_ATTR_CURRENT_HUE
    zuint8                u8CurrentHue;

where:

'Colour Information' Attribute Set Note that the attributes u8CurrentHue, u8CurrentSaturation, u16CurrentX,``u16CurrentY and u16ColourTemperatureMired are enabled as part of 'Colour Capabilities' groups - see Table 34 on page 704.

- u8CurrentHue is the current hue value of the light in the range 0-254. This value can be converted to hue in degrees using the following formula:

  hue = u8CurrentHue x 360/254. This attribute is only valid when the attributes u8CurrentSaturation and u8ColorMode are also implemented.

- u8CurrentSaturation is the current saturation value of the light in the range 0-254. This value can be converted to saturation as a fraction using the following formula: saturation = u8CurrentSaturation/254. This attribute is only valid when the attributes u8CurrentHue and u8ColorMode are also implemented.

- u16RemainingTime is the time duration, in tenths of a second, before the currently active command completes.

- u16CurrentX is the current value for the chromaticity x, as defined in the CIE xyY colour space, in the range 0-65279. The normal value of x is calculated using the following formula: x = u16CurrentX/65536.

- u16CurrentY is the current value for the chromaticity y, as defined in the CIE xyY colour space, in the range 0-65279. The normal value of y is calculated using the following formula: y = u16CurrentY/65536.

- u8DriftCompensation indicates the mechanism, if any, is being used to compensate for colour/intensity drift over time. One of the following values is specified:

u8DriftCompensation	Drift Compensation Mechanism
0x00	None
0x01	Other or unknown
0x02	Temperature monitoring
0x03	Optical luminance monitoring and feedback
0x04	Optical colour monitoring and feedback
0x05 - 0xFF	Reserved

- The following optional pair of attributes are used to store a textual indication of the drift compensation mechanism used:
  - sCompensationText is a tsZCL_CharacterString structure (see Section 6.1.14) for a character string representing the drift compensation method used

  - au8CompensationText[] is a byte-array which contains the character data bytes representing the drift compensation method used

- u16ColourTemperatureMired is the colour temperature of the light expressed as a micro reciprocal degree (mired) value. It is a scaled reciprocal of the current value of the colour temperature, in the range 1-65279

  (0 is undefined and 65535 indicates an invalid value). The colour temperature, in Kelvin, is calculated using the following formula:

  T = 1000000/u16ColourTemperature``Mired. This attribute is only valid when the attribute u8Colo``u``rMode is also implemented.

- u8ColourMode indicates which method is currently being used to control the colour of the light. One of the following values is specified:

u8ColourMode	Colour Control Method/Attributes
0x00	Hue and saturation

(u8CurrentHue and u8CurrentSaturation)

| |0x01|Chromaticities x and y from CIE xyY colour space

(u16CurrentX and u16CurrentY)

| |0x02|Colour temperature (u16ColourTemperature``Mired)| |0x03 - 0xFF|Reserved|

- u8Options is a bitmap which allows behaviors connected with certain commands to be defined (these behaviors should only be defined during commissioning), as follows:

Bits	Name	Description
0	Change	Defines whether changes to the Colour Control cluster can be made from control clusters (e.g. Level Control) when the bOnOff attribute of the On/Off cluster is zero (off):

  - 1 – Allow changes
  - 0 – Do not allow changes

| |1-7|-|Reserved|

'Defined Primaries Information'

- u8NumberOfPrimaries is the number of colour primaries implemented on the device, in the range 1-6 (0xFF is used if the number of primaries is unknown).
  - For each colour primary, there is a set of three attributes used (see below) - for example, for the first primary this attribute trio comprises u16Primary1X, u16Primary1Y and u8Primary1Intensity. Therefore, the number of primaries specified determines the number of these attribute trios used.

Note: The number of primaries is set using a macro at compile-time (see Section 31.9). This automatically enables the relevant u16PrimaryNX, u16PrimaryNY and u8PrimaryNIntensity (N=1 to 6) attributes.

- The attribute definitions below are valid for colour primary N, where N is 1, 2 or 3.
- u16PrimaryNX is the value for the chromaticity x for colour primary N, as defined in the CIE xyY colour space, in the range 0-65279. The normalized value of x is calculated using the following formula: x = u16PrimaryNX/65536.

- u16PrimaryNY is the value for the chromaticity y for colour primary N, as defined in the CIE xyY colour space, in the range 0-65279. The normalized value of y is calculated using the following formula: y = u16PrimaryNY/65536.
- u8PrimaryNIntensity is a representation of the maximum intensity of colour primary 1, normalized such that the primary with the highest maximum intensity has the value 0xFE.

'Additional Defined Primaries Information' Attribute Set

- The attribute definitions for this set are as for u16PrimaryNX, u16PrimaryNY and u8PrimaryNIntensity above, where N is 4, 5 or 6.
- As indicated in the Note above for the *'Defined Primaries Information' Attribute*Set, these attributes are enabled automatically according to the number of required primaries defined at compile-time (see Section 31.9).

'Defined Colour Points Settings'

- u16WhitePointX is the value for the chromaticity x for the white point of the device, as defined in the CIE xyY colour space, in the range 0-65279. The normalized value of x is calculated using the following formula:

  x = u16WhitePointX/65536.
- u16WhitePointY is the value for the chromaticity y for the white point of the device, as defined in the CIE xyY colour space, in the range 0-65279. The normalized value of y is calculated using the following formula:

  y = u16WhitePointY/65536.
- u16ColourPointRX is the value for the chromaticity x for the red colour point of the device, as defined in the CIE xyY colour space, in the range 0-65279. The normalized value of x is calculated using the following formula:

  x = u16ColourPointRX/65536.
- u16ColourPointRY is the value for the chromaticity y for the red colour point of the device, as defined in the CIE xyY colour space, in the range 0-65279. The normalized value of y is calculated using the following formula:

  y = u16ColourPointRY/65536.
- u8ColourPointRIntensity is a representation of the relative intensity of the red colour point of the device, normalized such that the colour point with the highest relative intensity has the value 0xFE (the value 0xFF indicates an invalid value).
- u16ColourPointGX is the value for the chromaticity x for the green colour point of the device, as defined in the CIE xyY colour space, in the range 0-65279. The normalized value of x is calculated using the following formula:

  x = u16ColourPointGX/65536.
- u16ColourPointGY is the value for the chromaticity y for the green colour point of the device, as defined in the CIE xyY colour space, in the range 0-65279. The normalized value of y is calculated using the following formula:

  y = u16ColourPointGY/65536.
- u8ColourPointGIntensity is a representation of the relative intensity of the green colour point of the device, normalized such that the colour point with the highest relative intensity has the value 0xFE (the value 0xFF indicates an invalid value).
- u16ColourPointBX is the value for the chromaticity x for the blue colour point of the device, as defined in the CIE xyY colour space, in the range 0-65279. The normalized value of x is calculated using the following formula:

x = u16ColourPointBX/65536.

- u16ColourPointBY is the value for the chromaticity y for the blue colour point of the device, as defined in the CIE xyY colour space, in the range 0-65279. The normalized value of y is calculated using the following formula:

  y = u16ColourPointBY/65536.

- u8ColourPointBIntensity is a representation of the relative intensity of the blue colour point of the device, normalized such that the colour point with the highest relative intensity has the value 0xFE (the value 0xFF indicates an invalid value).

Enhanced Colour Mode Attributes These attributes are enabled as part of 'Colour Capabilities' groups - see Table 34 onpage 704.

- u16EnhancedCurrentHue contains the current hue of the light in terms of (unequal) steps around the CIE colour 'triangle':
  - 8 most significant bits represent an index into the XY look-up table that contains the step values, thus indicating the current step used
  - 8 least significant bits represent a linear interpolation value between the current step and next step (up), facilitating a colour zoom
    - The value of the u8CurrentHue attribute is calculated from the above values.
- u8EnhancedColourMode indicates which method is currently being used to control the colour of the light. One of the following values is specified:

u8ColourMode	Colour Control Method/Attributes
0x00	Current hue and current saturation

(u8CurrentHue and u8CurrentSaturation)

| |0x01|Chromaticities x and y from CIE xyY colour space

(u16CurrentX and u16CurrentY)

| |0x02|Colour temperature (u16ColourTemperature``Mired)| |0x03|Enhanced hue and current saturation

(u16EnhancedCurrentHue and u8CurrentSaturation)

| |0x03 - 0xFF|Reserved|

- u8ColourLoopActive indicates whether the colour loop is currently active: 0x01 - active, 0x00 - not active (all other values are reserved). The colour loop follows the hue steps around the CIE colour 'triangle' by incrementing or decrementing the value of u16EnhancedCurrentHue.
- u8ColourLoopDirection indicates the current direction of the colour loop in terms of the direction of change of u16EnhancedCurrentHue:

  0x01 - incrementing, 0x00 - decrementing (all other values are reserved).

- u16ColourLoopTime is the period, in seconds, of a full colour loop - that is, the time to cycle all possible values of u16EnhancedCurrentHue.
- u16ColourLoopStartEnhancedHue indicates the value of u16EnhancedCurrentHue at which the colour loop must be started.
- u16ColourLoopStoredEnhancedHue contains the value of u16EnhancedCurrentHue at which the last colour loop completed (this value is stored on completing a colour loop).
- u16ColourCapabilities is a bitmap indicating the Colour Control cluster features (and attributes) supported by the device, as detailed below (a bit is set to '1' if the feature is supported or '0' otherwise):

Bits	Feature	Attributes
0	Hue/Saturation	“‘
u8CurrentHue		
u8CurrentSaturation		

```
|
|1|Enhanced Hue

 \(Hue/Saturation must also be supported\)

|```
u16EnhancedCurrentHue
```

| |2|Colour Loop

(Enhanced Hue must also be supported)

|“‘ u8ColourLoopActive u8ColourLoopDirection u16ColourLoopTime u16ColourLoopStartEnhancedHue u16ColourLoopStoredEnhancedHue u16ColourCapabilities

```
|
|3|CIE XY Values|```
u16CurrentX
u16CurrentY
```

| |4|Colour Temperature (Mired)|“‘ u16ColourTemperatureMired u16ColourTemperatureMiredPhyMin u16ColourTemperatureMiredPhyMax

```
|
|5-15|Reserved|-|

Macros are provided to select the required Colour Capabilities at compile-time - see [Table 34 on page
↪704](compile-time_options.md#id_d6675cb0-6090-4409-b15f-2c832f964ed4).

-  `u16ColourTemperature``Mired``PhyMin` indicates the minimum value \(supported by the hardware\)
↪of the mired colour temperature attribute.
-  `u16ColourTemperature``Mired``PhyMax` indicates the maximum value \(supported by the hardware\)
↪of the mired colour temperature attribute.
-  `u16CoupleColourTempToLevelMinMired` is an optional attribute that is used when the
↪`u16ColourTemperatureMired` attribute is coupled to the `u8CurrentLevel` attribute of the Level Control
↪cluster \(this is the case when the CoupleColorTempToLevel bit of the `u8Options` attribute of the Level
↪Control cluster is equal to 1\). `u16CoupleColourTempToLevelMinMired` specifies a lower bound on the
↪value of the `u16ColourTemperatureMired` attribute, where this lower bound corresponds to a
↪`u8CurrentLevel` value of 0xFE \(100%\). Note that because the colour temperature is represented as a
↪mired \(reciprocal\) value, a high value of `u8CurrentLevel` corresponds to a low value of
↪`u16ColourTemperatureMired` and the `16CoupleColourTempToLevelMinMired` attribute corresponds to
↪an upper bound on the value of the colour temperature supported by the device. The value of this attribute
↪must be at least equal to the value of `u16ColourTemperatureMiredPhyMin`.
-  `u16StartupColourTemperatureMired` is an optional attribute to define the required start-up colour
↪temperature of a light when it is supplied with power. It determines the initial value of
↪`u16ColourTemperatureMired` on start-up.

## Global Attributes
```

(continues on next page)

(continued from previous page)

```
- `u8AttributeReportingStatus` is an optional attribute that should be enabled when attribute reporting is␣
↪used for the cluster \(see [Section 2.3.5](../../ZCL_fundamentals/topics/attribute_reporting.md#id_
↪d3e2d682-d5e6-4aa5-870f-4d2e0320637e)\). The value of this attribute indicates whether there are attribute␣
↪reports still pending \(0x00\) or the attribute reports are complete \(0x01\) - all other values are reserved.␣
↪This attribute is also described in [Section 2.4](../../ZCL_fundamentals/topics/global_attributes.md#id_
↪8f80e769-8ccd-4b4f-8609-579f4457d527).

u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specification on which␣
↪this cluster instance is based. The cluster specification in the ZCLr6 corresponds to a cluster revision of 1.␣
↪The value is incremented by one for each subsequent revision of the cluster specification. This attribute is␣
↪also described in[Section2.4](../../ZCL_fundamentals/topics/global_attributes.md#id_8f80e769-8ccd-4b4f-
↪8609-579f4457d527).

**Parent topic:**[Colour Control Cluster](../../Colour_Control_cluster/topics/colour_control_cluster.md)
```

Attributes for Default Reporting The following attributes of the Colour Control cluster can be selected for default reporting:

```
u8CurrentHue
u8CurrentSaturation
u16CurrentX
```

- u16CurrentY

Attribute reporting (including default reporting) is described in *Appendix B.* Enabling reports for these attributes is described in Appendix B.3.6.

Parent topic:*Colour Control Cluster*

Initialization The function **eCLD_ColourControlCreateColourControl()** is used to create an instance of the Colour Control cluster. The function is generally called by the initialization function for the host device.

Parent topic:*Colour Control Cluster*

Sending Commands The NXP implementation of the ZCL provides functions for sending commands between a Colour Control cluster client and server. A command is sent from the client to one or more endpoints on the server. Multiple endpoints can usually be targeted using binding or group addressing.

Note: Any 'Move to', 'Move' or 'Step' command that is currently in progress can be stopped at any time by calling the function: **eCLD_ColourControlCommandStopMoveStepCommandSend()**

Controlling Hue Colour can be controlled in terms of hue, which is related to the dominant wavelength (or frequency) of the light emitted by a lighting device. On a device that supports the Colour Control cluster, the hue is controlled by means of the 'current hue' attribute (u8CurrentHue) of the cluster. This attribute can take a value in the range 0-254, which can be converted to hue in degrees using the following formula:

Hue in degrees = u8CurrentHue x 360/254

The 'current hue' attribute can be controlled in a number of ways using commands of the Colour Control cluster. API functions are available to send these commands to endpoints on remote devices.

'Move to Hue' Command The 'Move to Hue' command allows the 'current hue' attribute to be moved (increased or decreased) to a specified target value in a continuous manner over a specified transition time. This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandMoveToHueCommandSend()

Since the possible hues are represented on a closed boundary, the target hue can be reached by moving the attribute value in either direction, up or down (the attribute value wraps around). Options are also provided for taking the 'shortest route' and 'longest route' around the boundary.

'Move Hue' Command The 'Move Hue' command allows the 'current hue' attribute to be moved in a given direction (increased or decreased) at a specified rate indefinitely, until stopped. This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandMoveHueCommandSend()

Since the possible hues are represented on a closed boundary, the movement is cyclic (the attribute value wraps around). The above function can also be used to stop the movement.

'Step Hue' Command The 'Step Hue' command allows the 'current hue' attribute to be moved (increased or decreased) by a specified amount in a continuous manner over a specified transition time. This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandStepHueCommandSend()

Note: Hue can also be moved in conjunction with saturation, as described in Section 31.5.7. The 'enhanced' hue can be moved in similar ways, as described in Section 31.5.5.

Parent topic: Sending Commands

Controlling Saturation Colour can be controlled in terms of saturation, which is related to the spread of wavelengths (or frequencies) in the light emitted by a lighting device. On a device that supports the Colour Control cluster, the saturation is controlled by means of the 'current saturation' attribute (u8CurrentSaturation) of the cluster. This attribute can take a value in the range 0-254, which can be converted to saturation as a fraction using the following formula:

Saturation = u8CurrentSaturation/254

The 'current saturation' attribute can be controlled in a number of ways using commands of the Colour Control cluster. API functions are available to send these commands to endpoints on remote devices.

'Move to Saturation' Command The 'Move to Saturation' command allows the 'current saturation' attribute to be moved (increased or decreased) to a specified target value in a continuous manner over a specified transition time. This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandMoveToSaturationCommandSend()

'Move Saturation' Command The 'Move Saturation' command allows the 'current saturation' attribute to be moved in a given direction (increased or decreased) at a specified rate until stopped or until the current saturation reaches its minimum or maximum value. This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandMoveSaturationCommandSend()

The above function can also be used to stop the movement.

'Step Saturation' Command The 'Step Saturation' command allows the 'current saturation' attribute to be moved (increased or decreased) by a specified amount in a continuous manner over a specified transition time. This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandStepSaturationCommandSend()

Note: Saturation can also be moved in conjunction with hue, as described in Section 31.5.7.

Parent topic: Sending Commands

Controlling Colour (CIE x and y Chromaticities) Colour can be controlled in terms of the x and y chromaticities defined in the CIE xyY colour space. On a device that supports the Colour Control cluster, these values are controlled by means of the 'current x' attribute (u16CurrentX) and 'current y' attribute (u16CurrentY) of the cluster. Each of these attributes can take a value in the range 0-65279. The normalized x and y chromaticities can then be calculated from these values using the following formulae:

x = u16CurrentX/65536

y = u16CurrentY/65536

The x and y chromaticity attributes can be controlled in a number of ways using commands of the Colour Control cluster. API functions are available to send these commands to endpoints on remote devices.

'Move to Colour' Command The 'Move to Colour' command allows the 'current x' and 'current y' attributes to be moved (increased or decreased) to specified target values in a continuous manner over a specified transition time. This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandMoveToColourCommandSend()

'Move Colour' Command The 'Move Colour' command allows the 'current x' and 'current y' attributes to be moved in a given direction (increased or decreased) at specified rates until stopped or until both attributes reach their minimum or maximum value. This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandMoveColourCommandSend()

The above function can also be used to stop the movement.

'Step Colour' Command The 'Step Colour' command allows the 'current x' and 'current y' attributes to be moved (increased or decreased) by specified amounts in a continuous manner over a specified transition time. This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandStepColourCommandSend()

Parent topic: Sending Commands

Controlling Colour Temperature Colour can be controlled in terms of colour temperature, which is the temperature of an ideal black body which radiates light of a similar hue to that of the lighting device. On a device that supports the Colour Control cluster, the colour temperature is controlled by means of the 'mired colour temperature' attribute (u16ColourTemperature``Mired) of the cluster. This attribute stores a micro reciprocal degree (mired) value, which is a scaled reciprocal of the current value of the colour temperature of the light, in the range 1-65279. The colour temperature, in Kelvin, can be calculated from the attribute value using the following formula:

T = 1000000/u16ColourTemperature``Mired

Note: The movement of colour temperature through colour space always follows the 'Black Body Line'.

'Move to Colour Temperature' Command The 'Move to Colour Temperature' command allows the 'mired colour temperature' attribute to be moved (increased or decreased) to a specified target value in a continuous manner over a specified transition time. This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandMoveToColourTemperatureCommandSend()

'Move Colour Temperature' Command The 'Move Colour Temperature' command allows the 'mired colour temperature' attribute to be moved in a given direction (increased or decreased) at a specified rate until stopped. This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandMoveColourTemperatureCommandSend()

The above function can also be used to stop the movement.

Maximum and minimum values for the 'mired colour temperature' attribute during the movement are also specified. If the attribute value reaches the specified maximum or minimum before the required change has been achieved, the movement will automatically stop.

'Step Colour Temperature' Command The 'Step Colour Temperature' command allows the 'mired colour temperature' attribute to be moved (increased or decreased) by a specified amount in a continuous manner over a specified transition time. This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandStepColourTemperatureCommandSend()

Maximum and minimum values for the 'mired colour temperature' attribute during the movement are also specified. If the attribute value reaches the specified maximum or minimum before the required change has been achieved, the movement will automatically stop.

Parent topic: Sending Commands

Controlling 'Enhanced' Hue Colour can be controlled in terms of hue, which is related to the dominant wavelength (or frequency) of the light emitted by a lighting device. The hue can alternatively be controlled by means of the 'enhanced current hue' attribute (u16EnhancedCurrentHue), instead of the 'current hue' attribute (the 'current hue' attribute is automatically adjusted when the 'enhanced current hue' attribute value changes).

The 'enhanced current hue' attribute allows hue to be controlled on a finer scale than the 'current hue' attribute. Hue steps are defined in a look-up table and values between the steps can be achieved through linear interpolation. This 16-bit attribute value therefore comprises two 8-bit components, as described below.

Bits 15-8	Bits 7-0
Index into the look-up table that	

contains the hue step values, thus indicating the current step used

|Linear interpolation value between the

current step and next step (up)

|

Thus, if the current hue step value is *Hi* (where *i* is the relevant table index) and the linear interpolation value is *interp*, the 'enhanced' hue is given by the formula:

Enhanced hue = *Hi* + (*interp*/255) x (*Hi+1* - *Hi*)

To convert this hue to a value in degrees, it is then necessary to multiply by 360/255.

The 'enhanced current hue' attribute can be controlled in a number of ways using commands of the Colour Control cluster. API functions are available to send these commands to endpoints on remote devices.

Note: **Note:**These commands are issued by a cluster client and are performed on a cluster server. The look-up table is user-defined on the server. When this command is received by the server, the user-defined callback function that is invoked must read the entry with the specified index from the look-up table and calculate the corresponding 'enhanced' hue value.

'Enhanced Move to Hue' Command The 'Enhanced Move to Hue' command allows the 'enhanced current hue' attribute to be moved (increased or decreased) to a specified target value in a continuous manner over a specified transition time (the 'current hue' attribute is also moved to a value based on the target 'enhanced current hue' value). This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandEnhancedMoveToHueCommandSend()

Since the possible hues are represented on a closed boundary, the target hue can be reached by moving the attribute value in either direction, up or down (the attribute value wraps around). Options are also provided for taking the 'shortest route' and 'longest route' around the boundary.

'Enhanced Move Hue' Command The 'Enhanced Move Hue' command allows the 'enhanced current hue' attribute to be moved in a given direction (increased or decreased) at a specified rate indefinitely, until stopped (the 'current hue' attribute is also moved through values based on the 'enhanced current hue' value). This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandEnhancedMoveHueCommandSend()

The above function can also be used to stop the movement.

Since the possible hues are represented on a closed boundary, the movement is cyclic (the attribute value wraps around). The above function can also be used to stop the movement.

'Enhanced Step Hue' Command The 'Enhanced Step Hue' command allows the 'enhanced current hue' attribute to be moved (increased or decreased) by a specified amount in a continuous manner over a specified transition time (the 'current hue' attribute is also moved through values based on the 'enhanced current hue' value). This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandEnhancedStepHueCommandSend()

Note: Note 1: 'Enhanced' hue can also be moved in conjunction with saturation, as described in Section31.5.7.

Note: Note 2: The value of the 'enhanced current hue' attribute can be moved around a colour loop, as described in Section 31.5.6.

Parent topic: Sending Commands

Controlling a Colour Loop The colour of a device can be controlled by moving the value of the 'enhanced current hue' attribute around a colour loop corresponding to the CIE colour 'triangle' - refer to Section 31.5.5 for details of the 'enhanced current hue' attribute.

Movement along the colour loop can be controlled using the 'Colour Loop Set' command of the Colour Control cluster. A function is available to send this command to endpoints on remote devices.

'Colour Loop Set' Command The 'Colour Loop Set' command allows movement of the 'enhanced current hue' attribute value around the colour loop to be configured and started. The direction(up or down), start 'enhanced' hue and duration of the movement can be specified. This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandColourLoopSetCommandSend()

The above function can also be used to stop the movement.

Parent topic: Sending Commands

Controlling Hue and Saturation Colour can be completely specified in terms of hue and saturation, which respectively represent the dominant wavelength (or frequency) of the light and the spread of wavelengths (around the former) within the light. Therefore, the Colour Control cluster provides commands to change both the hue and saturation at the same time. In fact, commands are provided to control the values of the:

- 'current hue' and 'current saturation' attributes
- 'enhanced current hue' and 'current saturation' attributes

API functions are available to send these commands to endpoints on remote devices.

'Move to Hue and Saturation' Command The 'Move to Hue and Saturation' command allows the 'current hue' and 'current saturation'attributes to be moved to specified target values in a continuous manner over a specified transition time. This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandMoveToHueCommandSend()

'Enhanced Move to Hue and Saturation' Command The 'Enhanced Move to Hue and Saturation' command allows the 'enhanced current hue' and 'current saturation'attributes to be moved to specified target values in a continuous manner over a specified transition time. This command can be sent to an endpoint on a remote device using the function

eCLD_ColourControlCommandEnhancedMoveToHueAndSaturationCommandSend()

Parent topic: Sending Commands

Parent topic:*Colour Control Cluster*

Functions The following Colour Control cluster functions are provided in the NXP implementation of the ZCL:

- eCLD_ColourControlCreateColourControl
- eCLD_ColourControlCommandMoveToHueCommandSend
- eCLD_ColourControlCommandMoveHueCommandSend
- eCLD_ColourControlCommandStepHueCommandSend
- eCLD_ColourControlCommandMoveToSaturationCommandSend

- eCLD_ColourControlCommandMoveSaturationCommandSend
- eCLD_ColourControlCommandStepSaturationCommandSend
- eCLD_ColourControlCommandMoveToHueAndSaturationCommandSend
- eCLD_ColourControlCommandMoveToColourCommandSend
- eCLD_ColourControlCommandMoveColourCommandSend
- eCLD_ColourControlCommandStepColourCommandSend
- eCLD_ColourControlCommandEnhancedMoveToHueCommandSend
- eCLD_ColourControlCommandEnhancedMoveHueCommandSend
- eCLD_ColourControlCommandEnhancedStepHueCommandSend
- eCLD_ColourControlCommandEnhancedMoveToHueAndSaturationCommandSend
- eCLD_ColourControlCommandColourLoopSetCommandSend
- eCLD_ColourControlCommandStopMoveStepCommandSend
- eCLD_ColourControlCommandMoveToColourTemperatureCommandSend
- eCLD_ColourControlCommandMoveColourTemperatureCommandSend
- eCLD_ColourControlCommandStepColourTemperatureCommandSend
- eCLD_ColourControl_GetRGB

eCLD_ColourControlCreateColourControl

```
teZCL_Status eCLD_ColourControlCreateColourControl(
    tsZCL_ClusterInstance *psClusterInstance,
    bool_t bIsServer,
    tsZCL_ClusterDefinition *psClusterDefinition,
    void *pvEndPointSharedStructPtr,
    uint8 *pu8AttributeControlBits,
    tsCLD_ColourControlCustomDataStructure
    *psCustomDataStructure);
```

Description This function creates an instance of the Colour Control cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function creates a Colour Control cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions.

Note: This function must not be called for an endpoint on which a standard ZigBee device is used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function.

When used, this function must be the first Colour Control cluster function called in the application, and must be called after the stack has been started and after the ZCL has been initialized.

The function requires an array to be declared for internal use, which contains one element (of type **uint8**) for each attribute of the cluster. The array length should therefore equate to the total number of attributes supported by the Colour Control cluster. The function initializes the array elements to zero.

Parameters

- *psClusterInstance*: Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initializing individual structure fields.
- *bIsServer* : Type of cluster instance (server or client) to be created:
- TRUE - server
- FALSE - client
- *psClusterDefinition*: Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the Colour Control cluster. This parameter can refer to a pre-filled structure called sCLD_ColourControl which is provided in the **ColourControl.h** file.
- *pvEndPointSharedStructPtr*: Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_ColourControl which defines the attributes of Colour Control cluster. The function initializes the attributes with default values.
- *pu8AttributeControlBits*: Pointer to an array of **uint8** values, with one element for each attribute in the cluster (see above).
- *psCustomDataStructure*: Pointer to a structure containing the storage for internal functions of the cluster (see Section 31.7.1)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_ColourControlCommandMoveToHueCommandSend

```
teZCL_Status eCLD_ColourControlCommandMoveToHueCommandSend(
        uint8 u8SourceEndPointId,
        uint8 u8DestinationEndPointId,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        tsCLD_ColourControl_MoveToHueCommandPayload
    *psPayload);
```

Description This function sends a Move to Hue command to instruct a device to move its 'current hue' attribute to a target hue value in a continuous manner within a given time. The hue value, direction and transition time are specified in the payload of the command (see Section 31.7.2).

Since the possible hues are represented on a closed boundary, the target hue can be reached by moving the attribute value in either direction, up or down (the attribute value wraps around). Options are also provided for 'shortest route' and 'longest route' around the boundary.

The device receiving this message generates a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that 'hue and saturation' mode is selected by setting the 'colour mode' attribute to 0x00, if required. It can then move the 'current hue' value as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'current hue' attribute is enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *psDestinationAddress*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- **psPayload*: Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

This function invokes the ZigBee PRO stack function to transmit the data. In case an error is returned, call the **eZCL_GetLastZpsError()** function to get the error.

Parent topic: Functions

eCLD_ColourControlCommandMoveHueCommandSend

```
teZCL_Status eCLD_ColourControlCommandMoveHueCommandSend(
uint8 u8SourceEndPointId,
uint8 u8DestinationEndPointId,
tsZCL_Address *psDestinationAddress,
```

(continues on next page)

(continued from previous page)

```
uint8 *pu8TransactionSequenceNumber,
tsCLD_ColourControl_MoveHueCommandPayload
*psPayload);
```

Description This function sends a Move Hue command to instruct a device to move its 'current hue' attribute value in a given direction at a specified rate for an indefinite time. The direction and rate are specified in the payload of the command (see Section 31.7.2).

The command can request that the hue is moved up or down, or that existing movement is stopped. Since the possible hues are represented on a closed boundary, the movement is cyclic (the attribute value wraps around). Once started, the movement will continue until it is stopped.

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that 'hue and saturation' mode is selected by setting the 'colour mode' attribute to 0x00, if required. It can then move the 'current hue' value as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'current hue' attribute is enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- **psPayload*: Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_ColourControlCommandStepHueCommandSend

```
teZCL_Status eCLD_ColourControlCommandStepHueCommandSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ColourControl_StepHueCommandPayload
*psPayload);
```

Description This function sends a Step Hue command to instruct a device to increase or decrease its 'current hue' attribute by a specified 'step' value in a continuous manner within a given time. The step size, direction and transition time are specified in the payload of the command (see Section 31.7.2).

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that 'hue and saturation' mode is selected by setting the 'colour mode' attribute to 0x00, if required. It can then move the 'current hue' value as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'current hue' attribute is enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *psDestinationAddress*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- **psPayload*: Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN

- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ColourControl_MoveToSaturationCommandPayload
*psPayload);
```

Description This function sends a Move to Saturation command to instruct a device to move its 'current saturation' attribute to a target saturation value in a continuous manner within a given time. The saturation value and transition time are specified in the payload of the command (see Section 31.7.2).

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that 'hue and saturation' mode is selected by setting the 'colour mode' attribute to 0x00, if required. It can then move the 'current saturation' value as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'current saturation' attribute is enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP

teZCL_Status eCLD_ColourControlCommandMoveSaturationCommandSend(
uint8 u8SourceEndPointId,
uint8 u8DestinationEndPointId,
tsZCL_Address *psDestinationAddress,
uint8 *pu8TransactionSequenceNumber,
tsCLD_ColourControl_MoveSaturationCommandPayload
*psPayload);
```

Description This function sends a Move Saturation command to instruct a device to move its 'current saturation' attribute value in a given direction at a specified rate for an indefinite time. The direction and rate are specified in the payload of the command (see Section 31.7.2).

The command can request that the saturation is moved up or down, or that existing movement is stopped. Once started, the movement will continue until it is stopped. If the current saturation reaches its minimum or maximum value, the movement will automatically stop.

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that 'hue and saturation' mode is selected by setting the 'colour mode' attribute to 0x00, if required. It can then move the 'current saturation' value as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'current saturation' attribute is enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP

- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *psDestinationAddress*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- **psPayload*: Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL

    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ColourControl_StepSaturationCommandPayload
*psPayload);
```

Description This function sends a Step Saturation command to instruct a device to increase or decrease its ‘current saturation’ attribute by a specified ‘step’ value in a continuous manner within a given time. The step size, direction and transition time are specified in the payload of the command (see Section 31.7.2).

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that ‘hue and saturation’ mode is selected by setting the ‘colour mode’ attribute to 0x00, if required. It can then move the ‘current saturation’ value as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the ‘current saturation’ attribute is enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP

    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ColourControl_MoveToColourCommandPayload
    *psPayload);
```

Description This function sends a Move to Hue and Saturation command to instruct a device to move its 'current hue' and 'current saturation' attributes to target values in a continuous manner within a given time. The hue value, saturation value and transition time are specified in the payload of the command (see Section 31.7.2).

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that 'hue and saturation' mode is selected by setting the 'colour mode' attribute to 0x00, if required. It can then move the 'current hue' and 'current saturation' values as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing

an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'current hue' and 'current saturation' attributes are enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload*: Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_ColourControlCommandMoveToColourCommandSend

```
teZCL_Status eCLD_ColourControlCommandMoveToColourCommandSend(
        uint8 u8SourceEndPointId,
        uint8 u8DestinationEndPointId,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        tsCLD_ColourControl_MoveToColourCommandPayload
    *psPayload);
```

Description This function sends a Move to Colour command to instruct a device to move its 'current x' and 'current y' attributes to target values in a continuous manner within a given time (where x and y are the chromaticities from the CIE xyY colour space). The x-value, y-value and transition time are specified in the payload of the command (see Section 31.7.2).

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that 'chromaticities x and y' mode is selected by setting the 'colour mode' attribute to 0x01, if required. It can then move the 'current x' and 'current y' values as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'current x' and 'current y' attributes are enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *psDestinationAddress*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- **psPayload*: Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_ColourControlCommandMoveColourCommandSend

```
teZCL_Status eCLD_ColourControlCommandMoveColourCommandSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ColourControl_MoveColourCommandPayload
*psPayload);
```

Description This function sends a Move Colour command to instruct a device to move its 'current x' and 'current y' attribute values at a specified rate for each attribute for an indefinite time (where x and y are the chromaticities from the CIE xyY colour space). The rates are specified in the payload of the command (see Section 31.7.2 and each rate can be positive (increase) or negative (decrease).

Once started, the movement will continue until it is stopped. The movement can be stopped by calling this function with both rates set to zero. The movement will be automatically stopped when either of the attributes reaches its minimum of maximum value.

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that 'chromaticities x and y' mode is selected by setting the 'colour mode' attribute to 0x01, if required. It can then move the 'current x' and 'current y' values as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'current x' and 'current y' values attributes are enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *psDestinationAddress*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- **psPayload*: Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_ColourControlCommandStepColourCommandSend

```
teZCL_Status eCLD_ColourControlCommandStepColourCommandSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ColourControl_StepColourCommandPayload
*psPayload);
```

Description This function sends a Step Colour command to instruct a device to change its 'current x' and 'current y' attribute values by a specified 'step' value for each attribute in a continuous manner within a given time (where x and y are the chromaticities from the CIE xyY colour space). The step sizes and transition time are specified in the payload of the command (see Section 31.7.2), and each step size can be positive (increase) or negative (decrease).

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that 'chromaticities x and y' mode is selected by setting the 'colour mode' attribute to 0x01, if required. It can then move the 'current x' and 'current y' values as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'current x' and 'current y' values attributes are enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *psDestinationAddress*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- **psPayload*: Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL

- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_ColourControlCommandEnhancedMoveToHueCommandSend

```
teZCL_Status eCLD_ColourControlCommandEnhancedMoveToHueCommandSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ColourControl_EnhancedMoveToHueCommandPayload
*psPayload);
```

Description This function sends an Enhanced Move to Hue command to instruct a device to move its 'enhanced current hue' attribute to a target hue value in a continuous manner within a given time. The enhanced hue value, direction and transition time are specified in the payload of the command (see Section 31.7.2). The 'current hue' attribute is also moved to a value based on the target 'enhanced current hue' value.

Since the possible hues are represented on a closed boundary, the target hue can be reached by moving the attribute value in either direction, up or down (the attribute value wraps around). Options are also provided for 'shortest route' and 'longest route' around the boundary.

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that 'hue and saturation' mode is selected by setting the 'colour mode' attribute to 0x00 and that 'enhanced hue and saturation' mode is selected by setting the 'enhanced colour mode' attribute to 0x03, if required. It can then move the 'enhanced current hue' value as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'enhanced current hue' attribute is enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload*: Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_ColourControlCommandEnhancedMoveHueCommandSend

```
teZCL_Status eCLD_ColourControlCommandEnhancedMoveHueCommandSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ColourControl_EnhancedMoveHueCommandPayload
*psPayload);
```

Description This function sends an Enhanced Move Hue command to instruct a device to move its 'enhanced current hue' attribute value in a given direction at a specified rate for an indefinite time. The direction and rate are specified in the payload of the command (see Section 31.7.2). The 'current hue' attribute is also moved through values based on the 'enhanced current hue' value.

The command can request that the hue is moved up or down, or that existing movement is stopped. Since the possible hues are represented on a closed boundary, the movement is cyclic (the attribute value wraps around). Once started, the movement will continue until it is stopped.

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that 'hue and saturation' mode is selected by setting the 'colour mode' attribute to 0x00 and that 'enhanced hue and saturation' mode is selected by setting the 'enhanced colour mode' attribute to 0x03, if required. It can then move the 'enhanced current hue' value as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'enhanced current hue' attribute is enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values

- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *psDestinationAddress*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- **psPayload*: Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

eCLD_ColourControlCommandEnhancedStepHueCommandSend

```
teZCL_Status eCLD_ColourControlCommandEnhancedStepHueCommandSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ColourControl_EnhancedStepHueCommandPayload
*psPayload);
```

Description This function sends an Enhanced Step Hue command to instruct a device to increase or decrease its 'enhanced current hue' attribute by a specified 'step' value in a continuous manner within a given time. The step size, direction and transition time are specified in the payload of the command (see Section 31.7.2). The 'current hue' attribute is also moved through values based on the 'enhanced current hue' value.

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that 'hue and saturation' mode is selected by setting the 'colour mode' attribute to 0x00 and that 'enhanced hue and saturation' mode is selected by setting the 'enhanced colour mode' attribute to 0x03, if required. It can then move the 'enhanced current hue' value as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'enhanced current hue' attribute is enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *psDestinationAddress*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- **psPayload*: Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

eCLD_ColourControlCommandEnhancedMoveToHueAndSaturationCommandSend

```
teZCL_Status eCLD_ColourControlCommandEnhancedMoveToHueAndSaturationCommandSend(
        uint8 u8SourceEndPointId,
        uint8 u8DestinationEndPointId,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        tsCLD_ColourControl_EnhancedMoveToHueAndSaturation
    CommandPayload *psPayload);
```

Description This function sends an Enhanced Move to Hue and Saturation command to instruct a device to move its 'enhanced current hue' and 'current saturation' attributes to target values in a continuous manner within a given time. The enhanced hue value, saturation value and transition time are specified in the payload of the command (see Section 31.7.2). The 'current hue' attribute is also moved to a value based on the target 'enhanced current hue' value.

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that 'hue and saturation' mode is selected by setting the 'colour mode' attribute to 0x00 and that 'enhanced hue and saturation' mode is selected by setting the 'enhanced colour mode' attribute to 0x03, if required. It can then move the 'enhanced current hue' and 'current saturation' values as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'enhanced current hue' and 'current saturation' attributes are enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *psDestinationAddress*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- **psPayload*: Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

eCLD_ColourControlCommandColourLoopSetCommandSend

```
teZCL_Status eCLD_ColourControlCommandColourLoopSetCommandSend(
        uint8 u8SourceEndPointId,
        uint8 u8DestinationEndPointId,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        tsCLD_ColourControl_ColourLoopSetCommandPayload
    *psPayload);
```

Description This function sends a Colour Loop Set command to instruct a device to configure the movement of the 'enhanced current hue' attribute value around the colour loop corresponding to the CIE colour 'triangle'. The configured movement can be started in either direction and for a specific duration. The start hue, direction and duration are specified in the payload of the command (see Section 31.7.2). The 'current hue' attribute is also moved through values based on the 'enhanced current hue' value.

The function can also be used to stop existing movement around the colour loop.

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that 'hue and saturation' mode is selected by setting the 'colour mode' attribute to 0x00 and that 'enhanced hue and saturation' mode is selected by setting the 'enhanced colour mode' attribute to 0x03, if required. It can then move the 'enhanced current hue' value as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'enhanced current hue' attribute is enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *psDestinationAddress*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- **psPayload*: Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

eCLD_ColourControlCommandStopMoveStepCommandSend

```
teZCL_Status eCLD_ColourControlCommandStopMoveStepCommandSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ColourControl_StopMoveStepCommandPayload
*psPayload);
```

Description This function sends a Stop Move Step command to instruct a device to stop a 'Move to', 'Move' or 'Step' command that is currently in progress.

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered, and stop the current action.

The 'current hue', 'enhanced current hue' and 'current saturation' attributes will subsequently keep the values they have when the current action is stopped.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'enhanced current hue' attribute is enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload* : Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ColourControl_MoveToColourTemperatureCommandPayload
*psPayload);
```

Description This function sends a Move to Colour Temperature command to instruct a device to move its 'mired colour temperature' attribute to a target value in a continuous manner within a given time. The attribute value is a scaled reciprocal of colour temperature, as indicated in Section 31.5.4. The target attribute value, direction and transition time are specified in the payload of the command (see Section 31.7.2).

The movement through colour space will follow the 'Black Body Line'.

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that 'colour temperature' mode is selected by setting the 'colour mode' attribute to 0x02, if required. It can then move the 'mired colour temperature' value as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'mired colour temperature' attribute is enabled in the Colour Control cluster.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *psDestinationAddress*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- **psPayload*: Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL

- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND

eCLD_ColourControlCommandMoveColourTemperatureCommandSend

```
teZCL_Status eCLD_ColourControlCommandMoveColourTemperatureCommandSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ColourControl_MoveColourTemperatureCommandPayload
*psPayload);
```

Description This function sends a Move Colour Temperature command to instruct a device to move its 'mired colour temperature' attribute value in a given direction at a specified rate. The attribute value is a scaled reciprocal of colour temperature, as indicated in Section 31.5.4. The direction and rate are specified in the payload of the command (see Section 31.7.2). Maximum and minimum attribute values for the movement are also specified in the payload.

The command can request that the attribute value is moved up or down, or that existing movement is stopped. Once started, the movement will automatically stop when the attribute value reaches the specified maximum or minimum.

The movement through colour space will follow the 'Black Body Line'.

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that 'colour temperature' mode is selected by setting the 'colour mode' attribute to 0x02, if required. It can then move the 'mired colour temperature' value as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'mired colour temperature' attribute is enabled in the Colour Control cluster, as well as the 'mired colour temperature maximum' and 'mired colour temperature minimum' attributes.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP

- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- **psPayload*: Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND

eCLD_ColourControlCommandStepColourTemperatureCommandSend

```
teZCL_Status eCLD_ColourControlCommandStepColourTemperatureCommandSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ColourControl_StepColourTemperatureCommandPayload
*psPayload);
```

Description This function sends a Step Colour Temperature command to instruct a device to increase or decrease its ‘mired colour temperature’ attribute by a specified ‘step’ value in a continuous manner within a given time. The attribute value is a scaled reciprocal of colour temperature, as indicated in Section 31.5.4. The step size, direction and transition time are specified in the payload of the command (see Section 31.7.2). Maximum and minimum attribute values for the movement are also specified in the payload.

The command can request that the attribute value is moved up or down. If this value reaches the specified maximum or minimum before the required change has been achieved, the movement will automatically stop.

The movement through colour space will follow the ‘Black Body Line’.

The device receiving this message will generate a callback event on the endpoint on which the Colour Control cluster was registered. The device must first ensure that ‘colour temperature’ mode is selected by setting the ‘colour mode’ attribute to 0x02, if required. It can then move the ‘mired colour temperature’ value as requested.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

This function can only be used when the 'mired colour temperature' attribute is enabled in the Colour Control cluster, as well as the 'mired colour temperature maximum' and 'mired colour temperature minimum' attributes.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *psDestinationAddress*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- **psPayload*: Pointer to a structure containing the payload for this message (see Section 31.7.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND

Structures

Custom Data Structure The Colour Control cluster requires extra storage space to be allocated for use by internal functions. The structure definition for this storage is shown below:

```
typedef struct
{
    teCLD_ColourControl_ColourMode      eColourMode;
    uint16                              u16CurrentHue;
    tsCLD_ColourControl_Transition      sTransition;
    /* Matrices for XYZ <> RGB conversions */
    float                               afXYZ2RGB[3][3];
    float                               afRGB2XYZ[3][3];
    tsZCL_ReceiveEventAddress           sReceiveEventAddress;
    tsZCL_CallBackEvent                 sCustomCallBackEvent;
    tsCLD_ColourControlCallBackMessage sCallBackMessage;
} tsCLD_ColourControlCustomDataStructure;
```

The fields are for internal use and no knowledge of them is required.

Parent topic: Structures

Custom Command Payloads The following structures contain the payloads for the Colour Control cluster custom commands.

Move to Hue Command Payload

```
typedef struct
{
    uint8                           u8Hue;
    teCLD_ColourControl_Direction   eDirection;
    uint16                          u16TransitionTime;
} tsCLD_ColourControl_MoveToHueCommandPayload;
```

where:

- u8Hue is the target hue value.
- eDirection indicates the direction/path of the change in hue:

eDirection	Direction/Path
0x00	Shortest path
0x01	Longest path
0x02	Up
0x03	Down
0x04 – 0xFF	Reserved

- u16TransitionTime is the time period, in tenths of a second, over which the change in hue should be implemented.

Move Hue Command Payload

```
typedef struct
{
    teCLD_ColourControl_MoveMode     eMode;
    uint8                            u8Rate;
    zbmap8                             u8OptionsMask;
    zbmap8                             u8OptionsOverride;
} tsCLD_ColourControl_MoveHueCommandPayload;
```

where:

- eMode indicates the required action and/or direction of the change in hue:

eMode	Action/Direction
0x00	Stop existing movement in hue
0x01	Start increasing hue
0x02	Reserved
0x03	Start decreasing hue
0x04 – 0xFF	Reserved

- u8Rate is the required rate of movement in hue steps per second (a step is one unit of hue for the device).
- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Step Hue Command Payload

```
typedef struct
{
    teCLD_ColourControl_StepMode     eMode;
    uint8                            u8StepSize;
    uint8                            u8TransitionTime;
    zbmap8                             u8OptionsMask;
    zbmap8                             u8OptionsOverride;
} tsCLD_ColourControl_StepHueCommandPayload;
```

where:

- eMode indicates the required direction of the change in hue:

eMode	Action/Direction
0x00	Reserved
0x01	Increase hue
0x02	Reserved
0x03	Decrease hue
0x04 – 0xFF	Reserved

- u8StepSize is the amount by which the hue is to be changed (increased or decreased), in units of hue for the device.
- u8TransitionTime is the time period, in tenths of a second, over which the change in hue should be implemented.
- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Move To Saturation Command Payload

```
typedef struct
{
    uint8                   u8Saturation;
    uint16                  u16TransitionTime;
    zbmap8                  u8OptionsMask;
    zbmap8                  u8OptionsOverride;
} tsCLD_ColourControl_MoveToSaturationCommandPayload;
```

where:

- u8Saturation is the target saturation value.
- u16TransitionTime is the time period, in tenths of a second, over which the change in saturation should be implemented.
- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Move Saturation Command Payload

```
typedef struct
{
    teCLD_ColourControl_MoveMode    eMode;
    uint8                   u8Rate;
    zbmap8                  u8OptionsMask;
    zbmap8                  u8OptionsOverride;
} tsCLD_ColourControl_MoveSaturationCommandPayload;
```

where:

- eMode indicates the required action and/or direction of the change in saturation:

eMode	Action/Direction
0x00	Stop existing movement in hue
0x01	Start increasing saturation
0x02	Reserved
0x03	Start decreasing saturation
0x04 – 0xFF	Reserved

- u8Rate is the required rate of movement in saturation steps per second (a step is one unit of saturation for the device).
- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Step Saturation Command Payload

```
typedef struct
{
    teCLD_ColourControl_StepMode    eMode;
    uint8                           u8StepSize;
    uint8                           u8TransitionTime;
    zbmap8                            u8OptionsMask;
    zbmap8                            u8OptionsOverride;
} tsCLD_ColourControl_StepSaturationCommandPayload;
```

where:

- eMode indicates the required direction of the change in saturation:

eMode	Action/Direction
0x00	Reserved
0x01	Increase saturation
0x02	Reserved
0x03	Decrease saturation
0x04 – 0xFF	Reserved

- u8StepSize is the amount by which the saturation is to be changed (increased or decreased), in units of saturation for the device.
- u8TransitionTime is the time period, in tenths of a second, over which the change in hue should be implemented.
- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Move To Hue And Saturation Command Payload

```
typedef struct
{
    uint8                           u8Hue;
    uint8                           u8Saturation;
    uint16                          u16TransitionTime;
```

(continues on next page)

(continued from previous page)

```
    zbmap8                  u8OptionsMask;
    zbmap8                  u8OptionsOverride;
} tsCLD_ColourControl_MoveToHueAndSaturationCommandPayload;
```

where:

- u8Hue is the target hue value.
- u8Saturation is the target saturation value.
- 16TransitionTime is the time period, in tenths of a second, over which the change in hue and saturation should be implemented.
- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Move To Colour Command Payload

```
typedef struct
{
    uint16                  u16ColourX;
    uint16                  u16ColourY;
    uint16                  u16TransitionTime;
    zbmap8                    u8OptionsMask;
    zbmap8                    u8OptionsOverride;
} tsCLD_ColourControl_MoveToColourCommandPayload;
```

where:

- u16ColourX is the target x-chromaticity in the CIE xyY colour space
- u16ColourY is the target y-chromaticity in the CIE xyY colour space
- u16TransitionTime is the time period, in tenths of a second, over which the colour change should be implemented.
- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Move Colour Command Payload

```
typedef struct
{
    int16                   i16RateX;
    int16                   i16RateY;
    zbmap8                    u8OptionsMask;
    zbmap8                    u8OptionsOverride;
} tsCLD_ColourControl_MoveColourCommandPayload;
```

where:

- i16RateX is the required rate of movement of x-chromaticity in the CIE xyY colour space, in steps per second (a step is one unit of x-chromaticity for the device).

- i16RateY is the required rate of movement of y-chromaticity in the CIE xyY colour space, in steps per second (a step is one unit of y-chromaticity for the device).
- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Step Colour Command Payload

```
typedef struct
{
    int16                   i16StepX;
    int16                   i16StepY;
    uint16                   u16TransitionTime;
    zbmap8                    u8OptionsMask;
    zbmap8                    u8OptionsOverride;
} tsCLD_ColourControl_StepColourCommandPayload;
```

where:

- i16StepX is the amount by which the x-chromaticity in the CIE xyY colour space is to be changed (increased or decreased), in units of x-chromaticity for the device.
- i16StepY is the amount by which the y-chromaticity in the CIE xyY colour space is to be changed (increased or decreased), in units of y-chromaticity for the device.
- u16TransitionTime is the time period, in tenths of a second, over which the colour change should be implemented.
- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Move To Colour Temperature Command Payload

```
typedef struct
{
    uint16                  u16ColourTemperatureMired;
    uint16                  u16TransitionTime;
    zbmap8                    u8OptionsMask;
    zbmap8                    u8OptionsOverride;
} tsCLD_ColourControl_MoveToColourTemperatureCommandPayload;
```

where:

- u16ColourTemperature``Mired is the target value of the mired colour temperature attribute u16ColourTemperature``Mired (this value is a scaled reciprocal of colour temperature - for details, refer to the attribute description in Section 31.2).
- u16TransitionTime is the time period, in tenths of a second, over which the change in colour temperature should be implemented.
- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Move Colour Temperature Command Payload

```
typedef struct
{
    teCLD_ColourControl_MoveMode      eMode;
    uint16                            u16Rate;
    uint16                            u16ColourTemperatureMiredMin;
    uint16                            u16ColourTemperatureMiredMax;
    zbmap8                              u8OptionsMask;
    zbmap8                              u8OptionsOverride;
} tsCLD_ColourControl_MoveColourTemperatureCommandPayload;
```

where:

- eMode indicates the required action and/or direction of the change in the mired colour temperature attribute value:

eMode	Action/Direction
0x00	Stop existing movement in colour temperature
0x01	Start increasing mired colour temperature attribute value
0x02	Reserved
0x03	Start decreasing mired colour temperature attribute value
0x04 – 0xFF	Reserved

- u16Rate is the required rate of movement in mired colour temperature steps per second (a step is one unit of the mired colour temperature attribute).
- u16ColourTemperature``Mired``Min is the lower limit for the mired colour temperature attribute during the operation resulting from this command.
- u16ColourTemperature``Mired``Max is the upper limit for the mired colour temperature attribute during the operation resulting from this command.
- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Step Colour Temperature Command Payload

```
typedef struct
{
    teCLD_ColourControl_StepMode      eMode;
    uint16                            u16StepSize;
    uint16                            u16TransitionTime;
    uint16                            u16ColourTemperatureMiredMin;
    uint16                            u16ColourTemperatureMiredMax;
    zbmap8                              u8OptionsMask;
    zbmap8                              u8OptionsOverride;
} tsCLD_ColourControl_StepColourTemperatureCommandPayload;
```

where:

- eMode indicates the required direction of the change in the mired colour temperature attribute value:

eMode	Action/Direction
0x00	Reserved
0x01	Increase mired colour temperature attribute value
0x02	Reserved
0x03	Decrease mired colour temperature attribute value
0x04 – 0xFF	Reserved

- u16StepSize is the amount by which the mired colour temperature attribute is to be changed (increased or decreased).
- u16TransitionTime is the time period, in tenths of a second, over which the change in the mired colour temperature attribute should be implemented.
- u16ColourTemperature``Mired``Min is the lower limit for the mired colour temperature attribute during the operation resulting from this command.
- u16ColourTemperature``Mired``Max is the upper limit for the mired colour temperature attribute during the operation resulting from this command.
- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Enhanced Move To Hue Command Payload

```
typedef struct
{
    uint16                          u16EnhancedHue;
    teCLD_ColourControl_Direction       eDirection;
    uint16                          u16TransitionTime;
    zbmap8                            u8OptionsMask;
    zbmap8                            u8OptionsOverride;
} tsCLD_ColourControl_EnhancedMoveToHueCommandPayload;
```

where:

- u16EnhancedHue is the target 'enhanced' hue value in terms of a step around the CIE colour 'triangle' - for the format, refer to the description of the attribute u16EnhancedCurrentHue in Section 31.2.
- eDirection indicates the direction/path of the change in hue:

eDirection	Direction/Path
0x00	Shortest path
0x01	Longest path
0x02	Up
0x03	Down
0x04 – 0xFF	Reserved

- u16TransitionTime is the time period, in tenths of a second, over which the change in hue should be implemented.
- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Enhanced Move Hue Command Payload

```
typedef struct
{
    teCLD_ColourControl_MoveMode        eMode;
    uint16                              u16Rate;
    zbmap8                              u8OptionsMask;
    zbmap8                              u8OptionsOverride;
} tsCLD_ColourControl_EnhancedMoveHueCommandPayload;
```

where:

- eMode indicates the required action and/or direction of the change in hue:

eMode	Action/Direction
0x00	Stop existing movement in hue
0x01	Start increase in hue
0x02	Reserved
0x03	Start decrease in hue
0x04 – 0xFF	Reserved

- u16Rate is the required rate of movement in 'enhanced' hue steps per second (a step is one unit of hue for the device).
- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Enhanced Step Hue Command Payload

```
typedef struct
{
    teCLD_ColourControl_StepMode        eMode;
    uint16                              u16StepSize;
    uint16                              u16TransitionTime;
    zbmap8                              u8OptionsMask;
    zbmap8                              u8OptionsOverride;
} tsCLD_ColourControl_EnhancedStepHueCommandPayload;
```

where:

- eMode indicates the required direction of the change in hue:

eMode	Action/Direction
0x00	Reserved
0x01	Increase in hue
0x02	Reserved
0x03	Decrease in hue
0x04 – 0xFF	Reserved

- u16StepSize is the amount by which the 'enhanced' hue is to be changed (increased or decreased) - for the format, refer to the description of the attribute u16EnhancedCurrentHue in Section 31.2.
- u8TransitionTime is the time period, in tenths of a second, over which the change in hue should be implemented.

- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Enhanced Move To Hue And Saturation Command Payload

```
typedef struct
{
    uint16                          u16EnhancedHue;
    uint8                           u8Saturation;
    uint16                          u16TransitionTime;
    zbmap8                          u8OptionsMask;
    zbmap8                          u8OptionsOverride;
} tsCLD_ColourControl_EnhancedMoveToHueAndSaturationCommandPayload;
```

where:

- u16EnhancedHue is the target 'enhanced' hue value in terms of a step around the CIE colour 'triangle' - for the format, refer to the description of the attribute u16EnhancedCurrentHue in Section 31.2.
- u8Saturation is the target saturation value.
- 16TransitionTime is the time period, in tenths of a second, over which the change in hue and saturation should be implemented.
- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Colour Loop Set Command Payload

```
typedef struct
{
    uint8                           u8UpdateFlags;
    teCLD_ColourControl_LoopAction      eAction;
    teCLD_ColourControl_LoopDirection   eDirection;
    uint16                          u16Time;
    uint16                          u16StartHue;
    zbmap8                          u8OptionsMask;
    zbmap8                          u8OptionsOverride;
} tsCLD_ColourControl_ColourLoopSetCommandPayload;
```

where:

- u8UpdateFlags is a bitmap indicating which of the other fields of the structure must be set (a bit must be set to '1' to enable the corresponding field, and '0' otherwise):

Bits	Field
0	"'
eAction	

```
|
|1|```
eDirection
```

| |2|“‘ u16Time

```
|
|3|```
u16StartHue
```

| |4–7|Reserved|

- eAction indicates the colour loop action to be taken (if enabled through u8UpdateFlags), as one of:

Enumeration	Value	Action
E_CLD_COLOURCONTROL_COLOURLOOP_ACTION_		

DEACTIVATE

|0x00|Deactivate colour loop| |E_CLD_COLOURCONTROL_COLOURLOOP_ACTION_

ACTIVATE_FROM_START

|0x01|Activate colour loop from specified start (enhanced) hue value| |E_CLD_COLOURCONTROL_COLOURLOOP_ACTION_

ACTIVATE_FROM_CURRENT

|0x02|Activate colour from current (enhanced) hue value|

- eDirection indicates the direction to be taken around the colour loop (if enabled through u8UpdateFlags) in terms of the direction of change of u16EnhancedCurrentHue:

Enumeration	Value	Direction
E_CLD_COLOURCONTROL_COLOURLOOP_		

DIRECTION_DECREMENT

|0x00|Decrement current (enhanced) hue value| |E_CLD_COLOURCONTROL_COLOURLOOP_

DIRECTION_INCREMENT

|0x01|Increment current (enhanced) hue value|

- u16Time is the period, in seconds, of a full colour loop - that is, the time to cycle all possible values of u16EnhancedCurrentHue.
- u16StartHue is the value of u16EnhancedCurrentHue at which the colour loop is to be started (if enabled through u8UpdateFlags).
- OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Stop Move Step Command Payload

```
typedef struct
{
    zbmap8              u8OptionsMask;
    zbmap8              u8OptionsOverride;
} tsCLD_ColourControl_StopMoveStepCommandPayload;
```

where OptionsMask and OptionsOverride must be either both present or both not present. These fields are used in creating a temporary Options bitmap from the u8Options attribute. Each bit of the u8Options attribute is carried across to the temporary Options bitmap unless the corresponding bit of OptionsMask is set (to 1). In this case, the corresponding bit of OptionsOverride is used in the temporary Options bitmap instead.

Enumerations

teCLD_ColourControl_ClusterID The following structure contains the enumerations used to identify the attributes of the Colour Control cluster.

```
typedef enum
{
    E_CLD_COLOURCONTROL_ATTR_CURRENT_HUE                = 0x0000,
    E_CLD_COLOURCONTROL_ATTR_CURRENT_SATURATION,
    E_CLD_COLOURCONTROL_ATTR_REMAINING_TIME,
    E_CLD_COLOURCONTROL_ATTR_CURRENT_X,
    E_CLD_COLOURCONTROL_ATTR_CURRENT_Y,
    E_CLD_COLOURCONTROL_ATTR_DRIFT_COMPENSATION,
    E_CLD_COLOURCONTROL_ATTR_COMPENSATION_TEXT,
    E_CLD_COLOURCONTROL_ATTR_COLOUR_TEMPERATURE_MIRED,
    E_CLD_COLOURCONTROL_ATTR_COLOUR_MODE,
    E_CLD_COLOURCONTROL_ATTR_OPTIONS        = 0x000F,
    E_CLD_COLOURCONTROL_ATTR_NUMBER_OF_PRIMARIES    = 0x0010,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_1_X,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_1_Y,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_1_INTENSITY,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_2_X            = 0x0015,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_2_Y,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_2_INTENSITY,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_3_X            = 0x0019,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_3_Y,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_3_INTENSITY,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_4_X            = 0x0020,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_4_Y,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_4_INTENSITY,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_5_X            = 0x0024,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_5_Y,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_5_INTENSITY,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_6_X            = 0x0028,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_6_Y,
    E_CLD_COLOURCONTROL_ATTR_PRIMARY_6_INTENSITY,
    E_CLD_COLOURCONTROL_ATTR_WHITE_POINT_X          = 0x0030,
    E_CLD_COLOURCONTROL_ATTR_WHITE_POINT_Y,
    E_CLD_COLOURCONTROL_ATTR_COLOUR_POINT_R_X,
    E_CLD_COLOURCONTROL_ATTR_COLOUR_POINT_R_Y,
    E_CLD_COLOURCONTROL_ATTR_COLOUR_POINT_R_INTENSITY,
    E_CLD_COLOURCONTROL_ATTR_COLOUR_POINT_G_X        = 0x0036,
```

(continues on next page)

(continued from previous page)

    E_CLD_COLOURCONTROL_ATTR_COUPLE_COLOUR_TEMPERATURE_TO_LEVEL_MIN_
↪MIRED,
    E_CLD_COLOURCONTROL_ATTR_STARTUP_COLOUR_TEMPERATURE_MIRED = 0x4010,
} teCLD_ColourControl_ClusterID;
```

Parent topic: Enumerations

Parent topic:*Colour Control Cluster*

Compile-time Options To enable the Colour Control cluster in the code to be built, it is necessary to add the following to the **zcl_options.h** file:

```
#define CLD_COLOUR_CONTROL
```

In addition, to include the software for a cluster client or server or both, it is necessary to add one or both of the following to the same file:

```
#define COLOUR_CONTROL_CLIENT
#define COLOUR_CONTROL_SERVER
```

The Colour Cluster cluster attributes reside on the server only. Therefore, attributes should not be enabled in the **zcl_options.h** file for the cluster client.

Optional Attributes The optional attributes of the Colour Control cluster are enabled/disabled by defining the following in the **zcl_options.h** file:

- For optional attributes from the 'Colour Information' attribute set:
  - CLD_COLOURCONTROL_ATTR_REMAINING_TIME
  - CLD_COLOURCONTROL_ATTR_DRIFT_COMPENSATION
  - CLD_COLOURCONTROL_ATTR_COMPENSATION_TEXT
  - CLD_COLOURCONTROL_ATTR_COLOUR_MODE
    - Certain attributes from this attribute set are enabled through a '*Colour*Capabilities' Definition (see below) - these are u8CurrentHue, u8CurrentSaturation and u16ColourTemperatureMired.
- For optional attributes from the 'Defined Primaries Information' and 'Additional Defined Primaries Information' attribute sets, the macro
  - CLD_COLOURCONTROL_ATTR_NUMBER_OF_PRIMARIES

    * is used to define the required number of colour primaries, N, in the range 1 to 6 (0xFF can also be specified if the number of primaries is not known). This macro is used to automatically enable the required attributes from these attribute sets - for example, if N is set to 4 then the following attributes are enabled:
    * u16Primary1X, u16Primary1Y, u8Primary1Intensity, u16Primary2X, u16Primary2Y, u8Primary2Intensity, u16Primary3X, u16Primary3Y, u8Primary3Intensity, u16Primary4X, u16Primary4Y, u8Primary4Intensity.

- For optional attributes from the 'Defined Colour Points Settings' attribute set:
  - CLD_COLOURCONTROL_ATTR_WHITE_POINT_X
  - CLD_COLOURCONTROL_ATTR_WHITE_POINT_Y
  - CLD_COLOURCONTROL_ATTR_COLOUR_POINT_R_X
  - CLD_COLOURCONTROL_ATTR_COLOUR_POINT_R_Y
  - CLD_COLOURCONTROL_ATTR_COLOUR_POINT_R_INTENSITY
  - CLD_COLOURCONTROL_ATTR_COLOUR_POINT_G_X
  - CLD_COLOURCONTROL_ATTR_COLOUR_POINT_G_Y
  - CLD_COLOURCONTROL_ATTR_COLOUR_POINT_G_INTENSITY
  - CLD_COLOURCONTROL_ATTR_COLOUR_POINT_B_X
  - CLD_COLOURCONTROL_ATTR_COLOUR_POINT_B_Y
  - CLD_COLOURCONTROL_ATTR_COLOUR_POINT_B_INTENSITY
- For optional attributes from the 'Enhanced Colour Mode' attributes, the following must be defined:
  - CLD_COLOURCONTROL_ATTR_ENHANCED_COLOUR_MODE
  - CLD_COLOURCONTROL_ATTR_COLOUR_CAPABILITIES
    * The required 'Enhanced Colour Mode' attributes for a device must then be enabled through a *'Colour Capabilities' Definition* (see below).

Global Attributes Add this line to enable the optional Attribute Reporting Status attribute:

```
#define CLD_COLOURCONTROL_ATTR_ID_ATTRIBUTE_REPORTING_STATUS
```

Add this line to define the value (n) of the Cluster Revision attribute:

```
#define CLD_COLOURCONTROL_CLUSTER_REVISION <n>
```

The default value is 1, which corresponds to the revision of the cluster in the ZCL r6 specification (see Section 2.4).

'Colour Capabilities' Definition If required, certain 'Colour Information' attributes and all 'Enhanced Colour Mode' attributes must be enabled through a 'Colour Capabilities' definition. Attributes are enabled as a group according to the required capability/functionality. The capabilities are detailed in the table below, with their corresponding attributes and macros.

The above macros automatically invoke the macros for the individual attributes in the capability group. For example, E_CLD_COLOURCONTROL_ATTR_CURRENT_HUE is invoked for the attribute u8CurrentHue.

The enabled Colour Capabilities are reflected in the 'Enhanced Colour Mode' attribute (bitmap) u16ColourCapabilities.

Example Colour Capabilities definitions are provided below for different devices.

ZLO Extended Colour Light:

```
#define CLD_COLOURCONTROL_COLOUR_CAPABILITIES
        (COLOUR_CAPABILITY_HUE_SATURATION_SUPPORTED | \\
       COLOUR_CAPABILITY_ENHANCE_HUE_SUPPORTED  | \\
       COLOUR_CAPABILITY_COLOUR_LOOP_SUPPORTED | \\
       COLOUR_CAPABILITY_XY_SUPPORTED | \\
       COLOUR_CAPABILITY_COLOUR_TEMPERATURE_SUPPORTED)
```

ZLO Colour Light:

```
#define CLD_COLOURCONTROL_COLOUR_CAPABILITIES
           (COLOUR_CAPABILITY_HUE_SATURATION_SUPPORTED | \\
           COLOUR_CAPABILITY_ENHANCE_HUE_SUPPORTED    | \\
           COLOUR_CAPABILITY_COLOUR_LOOP_SUPPORTED    | \\
           COLOUR_CAPABILITY_XY_SUPPORTED)
```

ZLO Colour Temperature Light:

```
#define CLD_COLOURCONTROL_COLOUR_CAPABILITIES
      (COLOUR_CAPABILITY_COLOUR_TEMPERATURE_SUPPORTED)
```

Parent topic:*Colour Control Cluster*

Ballast Configuration Cluster This chapter describes the Ballast Configuration cluster, which is concerned with a configuring a lighting ballast that restricts the amount of light emitted by a set of lamps connected to the ballast.

The Ballast Configuration cluster has a Cluster ID of 0x0301.

- **Overview**
- **Cluster structure and attributes**
- **Functions**
- **Enumerations**
- **Compile-time options**

Part VI: HVAC Clusters This part comprises three chapters:

- *Chapter 33* details the **Thermostat** cluster
- *Chapter 34* details the **Fan Control** cluster
- *Chapter 35* details the **Thermostat UI Configuration** cluster

Thermostat Cluster This chapter outlines the Thermostat cluster, which provides an interface for configuring and controlling the functionality of a thermostat.

The Thermostat cluster has a Cluster ID of 0x0201.

Overview The Thermostat cluster is required in ZigBee devices as indicated in the table below.

	Server-side	Client-side
Mandatory in...	Thermostat	
Optional in...		Remote Control

The Thermostat cluster is enabled by defining CLD_THERMOSTAT in the **zcl_options.h** file.

The inclusion of the client or server software must be pre-defined in the application's compile-time options (in addition, if the cluster is to reside on a custom endpoint then the role of client or server must also be specified when creating the cluster instance).

The compile-time options for the Thermostat cluster are fully detailed in Section33.10.

The information that can potentially be stored in this cluster is organised into the following attribute sets:

- Thermostat Information
- Thermostat Settings

The attributes are listed and described next, in Section 33.2.

Parent topic:*Thermostat Cluster*

Thermostat Cluster structure and attributes The Thermostat cluster is contained in the following tsCLD_Thermostat structure:

```
typedef struct
{
#ifdef THERMOSTAT_SERVER
    zint16              i16LocalTemperature;
#ifdef CLD_THERMOSTAT_ATTR_OUTDOOR_TEMPERATURE

#endif
    zuint16                 u16ClusterRevision;
} tsCLD_Thermostat;
```

where:

'Thermostat Information' Attribute Set

- i16LocalTemperature is a mandatory attribute representing the measured temperature in degrees Celsius, as follows:
  - i16LocalTemperature = 100 x temperature in degrees Celsius
  - The possible values are used as follows:
  - 0x0000 to 0x7FFF represent positive temperatures from 0°C to 327.67ºC
  - 0x8000 indicates that the temperature measurement is invalid
  - 0x8001 to 0x954C are unused values
  - 0x954D to 0xFFFF represent negative temperatures from -273.15°C to
  - -1°C (in two's complement form)
- i16OutdoorTemperature is an optional attribute representing the outside temperature in degrees Celsius. This temperature is represented as described above for i16LocalTemperature.

- u8Occupancy is an optional attribute indicating whether the heated/cooled space has been detected as occupied. Bit 0 is used as a flag as follows (all other bits are reserved):
  - 1 = occupied
  - 0 = not occupied
- i16AbsMinHeatSetpointLimit is an optional attribute specifying the absolute minimum possible temperature of the heating setpoint (as determined by the manufacturer). This temperature is represented as described above for i16LocalTemperature.
- i16AbsMaxHeatSetpointLimit is an optional attribute specifying the absolute maximum possible temperature of the heating setpoint (as determined by the manufacturer). This temperature is represented as described above for i16LocalTemperature.
- i16AbsMinCoolSetpointLimit is an optional attribute specifying the absolute minimum possible temperature of the cooling setpoint (as determined by the manufacturer). This temperature is represented as described above for i16LocalTemperature.
- i16AbsMaxCoolSetpointLimit is an optional attribute specifying the absolute maximum possible temperature of the cooling setpoint (as determined by the manufacturer). This temperature is represented as described above for i16LocalTemperature.

'Thermostat Settings' Attribute Set

- u8PICoolingDemand is an optional attribute indicating the level of cooling required by the PI (Proportional Integral) control loop, if any, used by the thermostat. It is a percentage value and takes the value 0 when the thermostat is 'off' or in 'heating' mode.
- u8PIHeatingDemand is an optional attribute indicating the level of heating required by the PI (Proportional Integral) control loop, if any, used by the thermostat. It is a percentage value and takes the value 0 when the thermostat is 'off' or in 'cooling' mode.
- i8LocalTemperatureCalibration is an optional attribute representing a temperature offset (in the range -2.5°C to 2.5°C) that can be added to or subtracted from the displayed temperature:
  - i8LocalTemperatureCalibration = 100 x offset in degrees Celsius
  - The possible values are used as follows:
  - 0x00 to 0x19 represent positive offsets from 0°C to 2.5°C
  - 0x20 to 0xE6 are unused values
  - 0xE7 to 0xFF represent negative offets from -2.5°C to -1°C (in two's complement form)
- i16OccupiedCoolingSetpoint is an optional attribute specifying the cooling setpoint (target temperature) when the cooling space is occupied. The value is calculated as described above for the i16LocalTemperature attribute and must take a value in the range defined by the attributes i16MinCoolSetpointLimit and i16MaxCoolSetpointLimit. If it is not known whether the space is occupied, this attribute will be used as the cooling setpoint (rather than i16UnoccupiedCoolingSetpoint).
- i16OccupiedHeatingSetpoint is an optional attribute specifying the heating setpoint (target temperature) when the heating space is occupied. The value is calculated as described above for the i16LocalTemperature attribute and must take a value in the range defined by the attributes i16MinHeatSetpointLimit and i16MaxHeatSetpointLimit. If it is not known whether the space is occupied, this attribute will be used as the heating setpoint (rather than i16UnoccupiedHeatingSetpoint).

Note: i16OccupiedCoolingSetpoint must always be greater in value than i16OccupiedHeatingSetpoint by an amount at least equal to the value of i8MinSetpointDeadBand (below). An attempt to violate this condition will result in a default response with the status INVALID_VALUE.

- i16UnoccupiedCoolingSetpoint is an optional attribute specifying the cooling setpoint (target temperature) when the cooling space is unoccupied. The value is calculated as described

above for the i16LocalTemperature attribute and must take a value in the range defined by the attributes i16AbsMinCoolSetpointLimit and i16MaxCoolSetpointLimit. If it is not known whether the space is occupied, this attribute will not be used (i16OccupiedCoolingSetpoint will be used instead).

- i16``UnoccupiedHeatingSetpoint is an optional attribute specifying the heating setpoint (target temperature) when the heating space is unoccupied. The value is calculated as described above for the i16LocalTemperature attribute and must take a value in the range defined by the attributes i16Min``HeatS``etpointLimit and i16MaxHeatSetpointLimit. If it is not known whether the space is occupied, this attribute will not be used (i16Occupied``Heati``ngSetpoint will be used instead).

Note: i16UnoccupiedCoolingSetpoint must always be greater in value than i16``Unoc``cupiedHeatingSetpoint by an amount at least equal to the value of i8MinSetpointDeadBand (below). An attempt to violate this condition will result in a default response with the status INVALID_VALUE.

- i16MinHeatSetpointLimit is an optional attribute specifying the minimum possible temperature of the heating setpoint. This temperature is represented as described above for i16LocalTemperature. The value set must be greater than or equal to the value of i16AbsMinHeatSetpointLimit, which is also the default value for this attribute.
- i16MaxHeatSetpointLimit is an optional attribute specifying the maximum possible temperature of the heating setpoint. This temperature is represented as described above for i16LocalTemperature. The value set must be less than or equal to the value of i16AbsMaxHeatSetpointLimit, which is also the default value for this attribute.
- i16MinCoolSetpointLimit is an optional attribute specifying the minimum possible temperature of the cooling setpoint. This temperature is represented as described above for i16LocalTemperature. The value set must be greater than or equal to the value of i16AbsMinCoolSetpointLimit, which is also the default value for this attribute.
- i16MaxCoolSetpointLimit is an optional attribute specifying the maximum possible temperature of the cooling setpoint. This temperature is represented as described above for i16LocalTemperature. The value set must be less than or equal to the value of i16AbsMaxCoolSetpointLimit, which is also the default value for this attribute.

Note: The above four 'Limit' attributes can be set in the compile-time options using macros, as described in Section 33.10.

- i8MinSetpointDeadBand is an optional attribute specifying the minimum difference between the heating setpoint and cooling setpoint, in steps of 0.1°C. The attribute can take a value in the range 0x0A to 0x19, representing 1°C to 2.5°C. All other values are unused.
- u8RemoteSensing is an optional attribute comprising an 8-bit bitmap which indicates whether remote (networked) or internal sensors are being used to measure/detect the local temperature, outside temperature and occupancy. The bitmap is detailed in the table below.

Bit	Description
0	**Local temperature**

1 - Remote sensor

0 - Internal sensor

| |1|**Outside temperature**

1 - Remote sensor

0 - Internal sensor

| |2|**Occupancy**

1 - Remote sensor

0 - Internal sensor

| |3-7|Reserved|

- eControlSequenceOfOperation is an optional attribute representing the operational capabilities/environment of the thermostat. The possible values are indicated in the table below:

Value	Capabilities	Notes (seeeSystemMode)
0x00	Cooling only	Heat and Emergency Heating are not possible
0x01	Cooling with Reheat	Heat and Emergency Heating are not possible
0x02	Heating only	Cool and Pre-cooling are not possible
0x03	Heating with Reheat	Cool and Pre-cooling are not possible
0x04	Cooling and Heating	

4-pipes

|All modes are possible| |0x05|Cooling and Heating

4-pipes with Reheat

|All modes are possible| |0x06 – 0xFE|Reserved|-|

- eSystemMode is an optional attribute specifying the current operating mode of the thermostat. The possible modes/values are indicated in the table below:

Value	Description
0x00	Off
0x01	Auto
0x02	Reserved
0x03	Cool
0x04	Heat
0x05	Emergency Heating
0x06	Pre-cooling
0x07	Fan only
0x08 – 0xFE	Reserved

- u8AlarmMask is an optional attribute containing a 3-bit bitmap specifying which alarms are enabled from those listed in the table below (use of the Alarms cluster is also required):

Bit	Description
0	**Initialisation failure** (device failed to complete initialization at power-up)

1 - Alarm enabled

0 - Alarm disabled

| |1|**Hardware failure**

1 - Alarm enabled

0 - Alarm disabled

| |2|**Self-calibration failure**

1 - Alarm enabled

0 - Alarm disabled

| |3-7|Reserved|

Global Attributes

- u8AttributeReportingStatus is an optional attribute that should be enabled when attribute reporting is used for the cluster (see Section 2.3.5). The value of this attribute indicates whether there are attribute reports still pending (0x00) or the attribute reports are complete (0x01) - all other values are reserved. This attribute is also described in Section 2.4.
- u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specification on which this cluster instance is based. The cluster specification in the ZCL r6 corresponds to a cluster revision of 1. The value is incremented by one for each subsequent revision of the cluster specification. This attribute is also described in Section 2.4.

Parent topic:*Thermostat Cluster*

Attributes for Default Reporting The following attributes of the Thermostat cluster can be selected for default reporting:

```
i16LocalTemperature
u8PICoolingDemand
```

- u8PIHeatingDemand

Attribute reporting (including default reporting) is described in *Appendix B.* Enabling reports for these attributes is described in Appendix B.3.6.

Parent topic:*Thermostat Cluster*

Thermostat Operations The Thermostat cluster server is mandatory for some HVAC devices, such as the Thermostat device, while the cluster client can be used on a controlling device, such as the Remote Control device.

The sections below describe common operations using the Thermostat cluster.

Initialisation The function **eCLD_ThermostatCreateThermostat()** is used to create an instance of the Thermostat cluster. The function is generally called by the initialization function for the host device.

Parent topic: Thermostat Operations

Recording and Reporting the Local Temperature A record of the local temperature is kept in the mandatory attribute i16LocalTemperature on the cluster server - this attribute is fully detailed in Section 33.2. The value of this attribute can be updated by the server application using the function **eCLD_ThermostatSetAttribute()** - for example, as the result of a local temperature measurement.

The value of the attribute i16LocalTemperature can be regularly reported to a cluster client - for example, to allow the local temperature to be displayed to the user. This automated reporting can be configured and started on the server using the function **eCLD_ThermostatStartReportingLocalTemperature()**. Reports is sent regularly, but not periodically - maximum and minimum time-intervals between consecutive reports can be specified.

Parent topic: Thermostat Operations

Configuring Heating and Cooling Setpoints Functions are provided to update the following two optional attributes that are used to specify setpoints (target temperatures) for heating and cooling:

```
i16OccupiedHeatingSetpoint
i16OccupiedCoolingSetpoint
```

If both of these setpoints are used, the cooling setpoint value must be greater than the heating setpoint value. These attributes are fully detailed in Section 33.2.

These server attributes can be controlled remotely from a client using the function **eCLD_ThermostatCommandSetpointRaiseOrLowerSend()**, usually as the result of user input on a controlling device. This function is used on the client to send a SetpointRaiseOrLower command to the server to increase or decrease the value of one or both of these setpoint attributes by a specified amount. On receipt of this command, an E_CLD_THERMOSTAT_CMD_SETPOINT_RAISE_LOWER event is generated on the server to notify the server application.

The server application can modify the values of these attributes using the function **eCLD_ThermostatSetAttribute()**.

Note: These and other attributes of the Thermostat cluster can also be written and read using the general attribute access functions, as described in Section 2.3.

Parent topic: Thermostat Operations

Parent topic:*Thermostat Cluster*

Thermostat Events The Thermostat cluster has its own events that are handled through the callback mechanism outlined in *Chapter 3*. If a device uses the Thermostat cluster then Thermostat event handling must be included in the callback function for the associated endpoint, where this callback function is registered through the relevant endpoint registration function (for example, through **eHA_RegisterThermostatEndPoint()** for a Thermostat device). The relevant callback function will then be invoked when a Thermostat event occurs.

For a Thermostat event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsCLD_ThermostatCallBackMessage structure:

```
typedef struct
{
   uint8                    u8CommandId;
   union
   {
     tsCLD_Thermostat_SetpointRaiseOrLowerPayload
                          *psSetpointRaiseOrLowerPayload;
   } uMessage;
} tsCLD_ThermostatCallBackMessage;
```

The u8CommandId field of the above structure specifies the type of command that has been received - only one command type is possible and is described below.

E_CLD_THERMOSTAT_CMD_SETPOINT_RAISE_LOWER In the tsCLD_ThermostatCallBackMessage structure, the u8CommandId is set to E_CLD_THERMOSTAT_CMD_SETPOINT_RAISE_LOWER on the Thermostat cluster server when a SetpointRaiseOrLower command has been received. On receipt of this command, the Thermostat command handler will be invoked.

Parent topic:*Thermostat Cluster*

Functions The following Thermostat cluster functions are provided:

- **Function Page**
- eCLD_ThermostatCreateThermostat 733
- eCLD_ThermostatSetAttribute 735
- eCLD_ThermostatStartReportingLocalTemperature 736
- eCLD_ThermostatCommandSetpointRaiseOrLowerSend 737

eCLD_ThermostatCreateThermostat

```
teZCL_Status eCLD_ThermostatCreateThermostat(
    tsZCL_ClusterInstance *psClusterInstance,
    bool_t bIsServer,
    sZCL_ClusterDefinition *psClusterDefinition,
    void *pvEndPointSharedStructPtr,
    uint8 *pu8AttributeControlBits,
    tsCLD_ThermostatCustomDataStructure
    psCustomDataStructure);
```

Description This function creates an instance of the Thermostat cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function will create a Thermostat cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions.

Note: This function must not be called for an endpoint on which a standard ZigBee device (e.g. the Thermostat device) will be used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function.

When used, this function must be the first Thermostat cluster function called in the application, and must be called after the stack has been started and after the ZCL has been initialized.

The function requires an array to be declared for internal use, which contains one element (of type **uint8**) for each attribute of the cluster. The array length should therefore equate to the total number of attributes supported by the Thermostat cluster.

The function initializes the array elements to zero.

Parameters

- *psClusterInstance* Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initialising individual structure fields.
- *bIsServer* Type of cluster instance (server or client) to be created:
- TRUE - server
- FALSE - client
- *psClusterDefinition* Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the Thermostat cluster. This parameter can refer to a pre-filled structure called sCLD_``Thermostat which is provided in the **Thermostat.h** file.

- *pvEndPointSharedStructPtr* Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_``Thermostat which defines the attributes of Thermostat cluster. The function initializes the attributes with default values.
- *pu8AttributeControlBits* Pointer to an array of **uint8** values, with one element for each attribute in the cluster (see above).

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_ThermostatSetAttribute

```
teZCL_Status eCLD_ThermostatSetAttribute(
    uint8 u8SourceEndPointId,
    uint8 u8AttributeId,
    int16 i16AttributeValue);
```

Description This function can be used on a Thermostat cluster server to update the Thermostat attributes - specifically to write a value to one of the following attributes:

```
i16LocalTemperature
i16OccupiedCoolingSetpoint
i16OccupiedHeatingSetpoint
```

The function first checks whether the value to be written falls within the valid range for the relevant attribute. If not, it returns with status E_ZCL_ERR_INVALID_VALUE. If the server attempts to write to an attribute other than those specified above, the function returns with status E_ZCL_DENY_ATTRIBUTE_ACCESS. If the cluster does not exist, it returns with status E_ZCL_ERR_CLUSTER_NOT_FOUND.

Parameters

- *u8SourceEndPointId* Number of the endpoint on which the Thermostat cluster resides
- *u8AttributeId* Identifier of attribute to be updated, one of:
- E_CLD_THERMOSTAT_ATTR_ID_LOCAL_TEMPERATURE
- E_CLD_THERMOSTAT_ATTR_ID_OCCUPIED_COOLING_SETPOINT
- E_CLD_THERMOSTAT_ATTR_ID_OCCUPIED_HEATING_SETPOINT
- *i16AttributeValue* Value to be written to attribute

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_INVALID_VALUE

- E_ZCL_DENY_ATTRIBUTE_ACCESS
- E_ZCL_ERR_CLUSTER_NOT_FOUND

Parent topic: Functions

eCLD_ThermostatStartReportingLocalTemperature

```
teZCL_Status eCLD_ThermostatStartReportingLocalTemperature(
    uint8 u8SourceEndPointId,
    uint8 u8DstEndPointId,
    uint64 u64DstAddr,
    uint16 u16MinReportInterval,
    uint16 u16MaxReportInterval,
    int16 i16ReportableChange);
```

Description This function can be used on a Thermostat cluster server to start automatic reporting of the measured local temperature to a cluster client. The change to be reported can be configured through this function. Reports is sent regularly (but not periodically), within the specified maximum and minimum time-intervals between consecutive reports.

Parameters

- *u8SourceEndPointId* Number of the local endpoint on which the Thermostat cluster server resides
- *u8DstEndPointId* Number of the endpoint to which reports are to be sent on the destination node
- *u64DstAddr* IEEE/MAC address of destination node
- *u16MinReportInterval* Minimum time-interval, in seconds, between reports
- *u16MaxReportInterval* Maximum time-interval, in seconds, between reports
- *i16ReportableChange* Specifies the change to be reported

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_CLUSTER_NOT_FOUND

Parent topic: Functions

eCLD_ThermostatCommandSetpointRaiseOrLowerSend

```
teZCL_Status eCLD_ThermostatCommandSetpointRaiseOrLowerSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_Thermostat_SetpointRaiseOrLowerPayload
*psPayload);
```

Description This function can be used on a Thermostat cluster client to send a 'Setpoint Raise Or Lower' command to the cluster server. This command is used to increase or decrease the heating setpoint and/or cooling setpoint by requesting a change to the values of the attribute i16OccupiedHeatingSetpoint and/or the attribute i16OccupiedCoolingSetpoint. The relevant setpoint(s) and the required temperature change are specified in the command payload structure tsCLD_Thermostat_SetpointRaiseOrLowerPayload (see Section 33.9.3).

A pointer must be specified to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which the request is sent
- *u8DestinationEndPointId* Number of the remote endpoint to which the request is sent
- *psDestinationAddress* Pointer to a structure containing the address of the remote node to which the request is sent
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the request
- *psPayload* Pointer to the command payload (see Section33.9.3)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

Parent topic: Functions

Parent topic:*Thermostat Cluster*

Return codes The Thermostat cluster functions use the ZCL return codes defined in Section 7.2.

Parent topic:*Thermostat Cluster*

Enumerations

'Attribute ID' Enumerations The following structure contains the enumerations used to identify the attributes of the Thermostat cluster.

```
typedef enum
{
    E_CLD_THERMOSTAT_ATTR_ID_LOCAL_TEMPERATURE = 0x0000,
    E_CLD_THERMOSTAT_ATTR_ID_OUTDOOR_TEMPERATURE,
    E_CLD_THERMOSTAT_ATTR_ID_OCCUPANCY,
    E_CLD_THERMOSTAT_ATTR_ID_ABS_MIN_HEAT_SETPOINT_LIMIT,
    E_CLD_THERMOSTAT_ATTR_ID_ABS_MAX_HEAT_SETPOINT_LIMIT,
    E_CLD_THERMOSTAT_ATTR_ID_ABS_MIN_COOL_SETPOINT_LIMIT,
    E_CLD_THERMOSTAT_ATTR_ID_ABS_MAX_COOL_SETPOINT_LIMIT,
    E_CLD_THERMOSTAT_ATTR_ID_PI_COOLING_DEMAND,
    E_CLD_THERMOSTAT_ATTR_ID_PI_HEATING_DEMAND,
    E_CLD_THERMOSTAT_ATTR_ID_LOCAL_TEMPERATURE_CALIBRATION = 0x0010,
    E_CLD_THERMOSTAT_ATTR_ID_OCCUPIED_COOLING_SETPOINT,
    E_CLD_THERMOSTAT_ATTR_ID_OCCUPIED_HEATING_SETPOINT,
    E_CLD_THERMOSTAT_ATTR_ID_UNOCCUPIED_COOLING_SETPOINT,
    E_CLD_THERMOSTAT_ATTR_ID_UNOCCUPIED_HEATING_SETPOINT,
    E_CLD_THERMOSTAT_ATTR_ID_MIN_HEAT_SETPOINT_LIMIT,
    E_CLD_THERMOSTAT_ATTR_ID_MAX_HEAT_SETPOINT_LIMIT,
    E_CLD_THERMOSTAT_ATTR_ID_MIN_COOL_SETPOINT_LIMIT,
    E_CLD_THERMOSTAT_ATTR_ID_MAX_COOL_SETPOINT_LIMIT,
    E_CLD_THERMOSTAT_ATTR_ID_MIN_SETPOINT_DEAD_BAND,
    E_CLD_THERMOSTAT_ATTR_ID_REMOTE_SENSING,
    E_CLD_THERMOSTAT_ATTR_ID_CONTROL_SEQUENCE_OF_OPERATION,
    E_CLD_THERMOSTAT_ATTR_ID_SYSTEM_MODE,
    E_CLD_THERMOSTAT_ATTR_ID_ALARM_MASK
} teCLD_Thermostat_AttributeID;
```

Parent topic: Enumerations

'Operating Capabilities' Enumerations The following enumerations are used to set the optional attribute eControlSequenceOfOperation in the Thermostat cluster structure tsCLD_Thermostat.

```
typedef enum
{
    E_CLD_THERMOSTAT_CSOO_COOLING_ONLY = 0x00,
    E_CLD_THERMOSTAT_CSOO_COOLING_WITH_REHEAT,
    E_CLD_THERMOSTAT_CSOO_HEATING_ONLY,
    E_CLD_THERMOSTAT_CSOO_HEATING_WITH_REHEAT,
    E_CLD_THERMOSTAT_CSOO_COOLING_AND_HEATING_4_PIPES,
    E_CLD_THERMOSTAT_CSOO_COOLING_AND_HEATING_4_PIPES_WITH_REHEAT,
}teCLD_Thermostat_ControlSequenceOfOperation;
```

The above enumerations are described in the table below.

Enumeration	Description
E_CLD_THERMOSTAT_CSOO_COOLING_ONLY	Heat and Emergency Heating are not

possible

| |E_CLD_THERMOSTAT_CSOO_COOLING_WITH_REHEAT|Heat and Emergency Heating are not

possible

| |E_CLD_THERMOSTAT_CSOO_HEATING_ONLY|Cool and Pre-cooling are not possible| |E_CLD_THERMOSTAT_CSOO_HEATING_WITH_REHEAT|Cool and Pre-cooling are not possible| |E_CLD_THERMOSTAT_CSOO_COOLING_AND_HEATING_

4_PIPES

|All modes are possible| |E_CLD_THERMOSTAT_CSOO_COOLING_AND_HEATING_

4_PIPES_WITH_REHEAT

|All modes are possible|

Parent topic: Enumerations

'Command ID' Enumerations The following enumeration is used to specify the type of command sent to a Thermostat cluster server.

```
typedef enum
{
  E_CLD_THERMOSTAT_CMD_SETPOINT_RAISE_LOWER = 0x00,
} teCLD_Thermostat_Command;
```

The above enumerations are described in the table below.

Enumeration	Command
E_CLD_THERMOSTAT_CMD_SETPOINT_RAISE_LOWER	Setpoint Raise Or Lower

Parent topic: Enumerations

'Setpoint Raise Or Lower' Enumerations The following enumerations are used to specify an operating mode (heating, cooling or both) or the Thermostat.

```
{
   E_CLD_THERMOSTAT_SRLM_HEAT = 0x00,
   E_CLD_THERMOSTAT_SRLM_COOL,
   E_CLD_THERMOSTAT_SRLM_BOTH
}teCLD_Thermostat_SetpointRaiseOrLowerMode;
```

The above enumerations are described in the table below.

Enumeration	Description
E_CLD_THERMOSTAT_SRLM_HEAT	Heating mode
E_CLD_THERMOSTAT_SRLM_COOL	Cooling mode
E_CLD_THERMOSTAT_SRLM_BOTH	Heating and Cooling modes

Parent topic: Enumerations

Parent topic:*Thermostat Cluster*

Structures

Custom Data Structure The Thermostat cluster requires extra storage space to be allocated for use by internal functions. The structure definition for this storage is shown below:

```
typedef struct
{
   tsZCL_ReceiveEventAddress          sReceiveEventAddress;
   tsZCL_CallBackEvent                sCustomCallBackEvent;
   tsCLD_ThermostatCallBackMessage    sCallBackMessage;
```

(continues on next page)

(continued from previous page)

```
} tsCLD_ThermostatCustomDataStructure;
```

The fields are for internal use and no knowledge of them is required.

Parent topic: Structures

tsCLD_ThermostatCallBackMessage For a Thermostat cluster event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsCLD_ThermostatCallBackMessage structure:

```
typedef struct
{
    uint8                                   u8CommandId;
    union
    {
      tsCLD_Thermostat_SetpointRaiseOrLowerPayload *psSetpointRaiseOrLowerPayload;
    } uMessage;
} tsCLD_ThermostatCallBackMessage;
```

where:

- u``8CommandId indicates the type of Thermostat cluster command that has been received - there is only one possibility: E_CLD_THERMOSTAT_CMD_SETPOINT_RAISE_LOWER
- u``Message is a union containing the command payload in the following form: psSetpointRaiseOrLowerPayload is a pointer to a structure containing the payload of a 'Setpoint Raise Or Lower' command - see Section 33.9.3.

Parent topic: Structures

tsCLD_Thermostat_SetpointRaiseOrLowerPayload This stucture contains the payload of a 'Setpoint Raise Or Lower' command (from the cluster client) which requests a change the value of the attribute i16OccupiedHeatingSetpoint and/or the attribute i16OccupiedCoolingSetpoint.

```
typedef struct
{
    zenum8                eMode;
    zint8                 i8Amount;
}tsCLD_Thermostat_SetpointRaiseOrLowerPayload;
```

where:

- eMode indicates the Thermostat operating mode to which the command relates, one of:
  - E_CLD_THERMOSTAT_SRLM_HEAT (Heating)
  - E_CLD_THERMOSTAT_SRLM_COOL (Cooling)
  - E_CLD_THERMOSTAT_SRLM_BOTH (Heating and Cooling)
- i8Amount represents the value (in two's complement form) by which the setpoint corresponding to the specified operating mode is to be changed

Parent topic: Structures

Parent topic:*Thermostat Cluster*

Compile-time options To enable the Thermostat cluster in the code to be built, it is necessary to add the following to the **zcl_options.h** file:

```
#define CLD_THERMOSTAT
```

In addition, to include the software for a cluster client or server or both, it is necessary to add one or both of the following to the same file:

```
#define THERMOSTAT_SERVER
#define THERMOSTAT_CLIENT
```

Optional Attributes The optional attributes for the Thermostat cluster (see Section 33.2) are enabled by defining:

- CLD_THERMOSTAT_ATTR_ID_LOCAL_TEMPERATURE
- CLD_THERMOSTAT_ATTR_ID_OUTDOOR_TEMPERATURE
- CLD_THERMOSTAT_ATTR_ID_OCCUPANCY
- CLD_THERMOSTAT_ATTR_ID_ABS_MIN_HEAT_SETPOINT_LIMIT
- CLD_THERMOSTAT_ATTR_ID_ABS_MAX_HEAT_SETPOINT_LIMIT
- CLD_THERMOSTAT_ATTR_ID_ABS_MIN_COOL_SETPOINT_LIMIT
- CLD_THERMOSTAT_ATTR_ID_ABS_MAX_COOL_SETPOINT_LIMIT
- CLD_THERMOSTAT_ATTR_ID_PI_COOLING_DEMAND
- CLD_THERMOSTAT_ATTR_ID_PI_HEATING_DEMAND
- CLD_THERMOSTAT_ATTR_ID_LOCAL_TEMPERATURE_CALIBRATION
- CLD_THERMOSTAT_ATTR_ID_OCCUPIED_COOLING_SETPOINT
- CLD_THERMOSTAT_ATTR_ID_OCCUPIED_HEATING_SETPOINT
- CLD_THERMOSTAT_ATTR_ID_UNOCCUPIED_COOLING_SETPOINT
- CLD_THERMOSTAT_ATTR_ID_UNOCCUPIED_HEATING_SETPOINT
- CLD_THERMOSTAT_ATTR_ID_MIN_HEAT_SETPOINT_LIMIT
- CLD_THERMOSTAT_ATTR_ID_MAX_HEAT_SETPOINT_LIMIT
- CLD_THERMOSTAT_ATTR_ID_MIN_COOL_SETPOINT_LIMIT
- CLD_THERMOSTAT_ATTR_ID_MAX_COOL_SETPOINT_LIMIT
- CLD_THERMOSTAT_ATTR_ID_MIN_SETPOINT_DEAD_BAND
- CLD_THERMOSTAT_ATTR_ID_REMOTE_SENSING
- CLD_THERMOSTAT_ATTR_ID_CONTROL_SEQUENCE_OF_OPERATION
- CLD_THERMOSTAT_ATTR_ID_SYSTEM_MODE
- CLD_THERMOSTAT_ATTR_ID_ALARM_MASK

Global Attributes Add this line to enable the optional Attribute Reporting Status attribute:

```
#define CLD_THERMOSTAT_ATTR_ID_ATTRIBUTE_REPORTING_STATUS
```

Add this line to define the value (n) of the Cluster Revision attribute:

```
#define CLD_THERMOSTAT_CLUSTER_REVISION <n>
```

The default value is 1, which corresponds to the revision of the cluster in the ZCL r6 specification (see Section 2.4).

Minimum Cooling Setpoint The value of the attribute i16MinCoolSetpointLimit can be set as follows:

```
#define CLD_THERMOSTAT_MIN_COOLING_SETPOINT        n
```

where n is the value to be set (in two's complement form). The default value is 0x954D.

Maximum Cooling Setpoint The value of the attribute i16MaxCoolSetpointLimit can be set as follows:

```
#define CLD_THERMOSTAT_MAX_COOLING_SETPOINT n
```

where n is the value to be set (in two's complement form). The default value is 0x7FFF.

Minimum Heating Setpoint The value of the attribute i16MinHeatSetpointLimit can be set as follows:

```
#define CLD_THERMOSTAT_MIN_HEATING_SETPOINT n
```

where n is the value to be set (in two's complement form). The default value is 0x954D.

Maximum Heating Setpoint The value of the attribute i16MaxHeatSetpointLimit can be set as follows:

```
#define CLD_THERMOSTAT_MAX_HEATING_SETPOINT n
```

where n is the value to be set (in two's complement form). The default value is 0x7FFF.

Parent topic:*Thermostat Cluster*

Fan Control Cluster This chapter describes the Fan Control cluster which is defined in the ZCL.

The Fan Control cluster has a Cluster ID of 0x0202.

Overview The Fan Control cluster is used to control the speed of a fan which may be part of a heating or cooling system. It allows the speed or state of the fan to be set, as well as the possible speeds/states that a thermostat can set.

To use the functionality of this cluster, you must include the file **FanControl.h** in your application and enable the cluster by defining CLD_FAN_CONTROL in the **zcl_options.h** file.

A Fan Control cluster instance can act as a client or a server. The inclusion of the client or server software must be pre-defined in the application's compile-time options (in addition, if the cluster is to reside on a custom endpoint then the role of client or server must also be specified when creating the cluster instance).

The compile-time options for the Fan Control cluster are fully detailed in Section 34.6.

Parent topic:*Fan Control Cluster*

Fan Control Structure and Attributes The structure definition for the Fan Control cluster is shown below.

```
typedef struct
{
    #ifdef FAN_CONTROL_SERVER
        zenum8  e8FanMode;
        zenum8  e8FanModeSequence;
    #endif
    zuint16 u16ClusterRevision;
} tsCLD_FanControl;
```

where:

- e8FanMode is a server attribute that represents the current speed/state of the fan. The attribute can be set to one of the enumerated values listed in Section34.5.2, representing off, low, medium, high, on, auto or smart.
- e8FanModeSequence is a server attribute that specifies the possible fan speeds/states that a thermostat can set. The attribute can be set to one of the enumerated values listed in Section 34.5.3, each representing a set of possible fan speeds/states.
- u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specification on which this cluster instance is based. The cluster specification in the ZCL r6 corresponds to a cluster revision of 1. The value is incremented by one for each subsequent revision of the cluster specification. For cluster specifications that pre-date the ZCL r6, this attribute is set to 0.

Parent topic:*Fan Control Cluster*

Initialisation The function **eCLD_CreateFanControl()** is used to create an instance of the Fan Control cluster. The function is generally called by the initialisation function for the host device.

Parent topic:*Fan Control Cluster*

Functions The following Fan Control cluster function is provided in the NXP implementation of the ZCL:

- **Function Page**
- eCLD_CreateFanControl 747

eCLD_CreateFanControl

```
teZCL_Status eCLD_CreateFanControl(
    tsZCL_ClusterInstance *psClusterInstance,
    bool_t bIsServer,
    tsZCL_ClusterDefinition *psClusterDefinition,
    void *pvEndPointSharedStructPtr,
    uint8 *pu8AttributeControlBits);
```

Description This function creates an instance of the Fan Control cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function will create a Fan Control cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions.

Note: This function must not be called for an endpoint on which a standard ZigBee device is used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function.

When used, this function must be called after the stack has been started and after the application profile has been initialized.

Parameters

- *psClusterInstance* Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initialising individual structure fields.
- *bIsServer* Type of cluster instance (server or client) to be created:
- TRUE - server
- FALSE - client
- *psClusterDefinition* Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the Fan Control cluster. This parameter can refer to a pre-filled structure called tsCLD_FanControl which is provided in the **FanControl.h** file.
- *pvEndPointSharedStructPtr* Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_FanControl which defines the attributes of the Fan Control cluster. The function initializes the attributes with default values.
- *pu8AttributeControlBits* Pointer to an array of **uint8** values, with one element for each attribute in the cluster (see above).

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL

Parent topic: Functions

Parent topic:*Fan Control Cluster*

Enumerations

teCLD_FanControl_AttributeID The following structure contains the enumerations used to identify the server attributes of the Fan Control cluster.

```
typedef enum
{
    E_CLD_FAN_CONTROL_ATTR_ID_FAN_MODE              = 0x0000,
    E_CLD_FAN_CONTROL_ATTR_ID_FAN_MODE_SEQUENCE,
```

(continues on next page)

(continued from previous page)

```
} teCLD_FanControl_AttributeID;
```

Parent topic: Enumerations

teCLD_FC_FanMode The following structure contains the enumerations used to set the value of the e8FanMode attribute in the tsCLD_FanControl structure (see Section 34.2).

```
typedef enum
{
    E_CLD_FC_FAN_MODE_OFF       = 0x00,
    E_CLD_FC_FAN_MODE_LOW,      //0x01
    E_CLD_FC_FAN_MODE_MEDIUM,   //0x02
    E_CLD_FC_FAN_MODE_HIGH,     //0x03
    E_CLD_FC_FAN_MODE_ON,       //0x04
    E_CLD_FC_FAN_MODE_AUTO,     //0x05
    E_CLD_FC_FAN_MODE_SMART,    //0x06
} teCLD_FC_FanMode;
```

The above enumerations are described in the table below.

Enumeration	Description (Fan State/Speed)
E_CLD_FC_FAN_MODE_OFF	Off
E_CLD_FC_FAN_MODE_LOW	Low
E_CLD_FC_FAN_MODE_MEDIUM	Medium
E_CLD_FC_FAN_MODE_HIGH	High
E_CLD_FC_FAN_MODE_ON	On
E_CLD_FC_FAN_MODE_AUTO	Auto (fan speed is self-regulated)
E_CLD_FC_FAN_MODE_SMART	Smart (when the space is occupied, the fan is always on)

Parent topic: Enumerations

teCLD_FC_FanModeSequence The following structure contains the enumerations used to set the value of the e8FanModeSequence attribute in the tsCLD_FanControl structure (see Section34.2).

```
typedef enum
{
    E_CLD_FC_FAN_MODE_SEQUENCE_LOW_MED_HIGH         = 0x00,
    E_CLD_FC_FAN_MODE_SEQUENCE_LOW_HIGH,            //0x01
    E_CLD_FC_FAN_MODE_SEQUENCE_LOW_MED_HIGH_AUTO,   //0x02
    E_CLD_FC_FAN_MODE_SEQUENCE_LOW_HIGH_AUTO,       //0x03
    E_CLD_FC_FAN_MODE_SEQUENCE_ON_AUTO,             //0x04
} teCLD_FC_FanModeSequence;
```

The above enumerations are described in the table below (the fan speeds/states refer to those listed in Section 34.5.2).

Enumeration	Description (Set of Fan Speeds/States)
E_CLD_FC_FAN_MODE_SEQUENCE_LOW_MED_HIGH	Low/Med/High
E_CLD_FC_FAN_MODE_SEQUENCE_LOW_HIGH	Low/High
E_CLD_FC_FAN_MODE_SEQUENCE_LOW_MED_HIGH_A	Low/Med/High/Auto
E_CLD_FC_FAN_MODE_SEQUENCE_LOW_HIGH_AUTO	Low/High/Auto
E_CLD_FC_FAN_MODE_SEQUENCE_ON_AUTO	On/Auto

Parent topic:*Fan Control Cluster*

Compile-time options To enable the Fan Control cluster in the code to be built, it is necessary to add the following to the **zcl_options.h** file:

```
#define CLD_FAN_CONTROL
```

In addition, to include the software for a cluster client or server or both, it is necessary to add one or both of the following to the same file:

```
#define FAN_CONTROL_CLIENT
#define FAN_CONTROL_SERVER
```

Parent topic:*Fan Control Cluster*

Thermostat UI Configuration Cluster This chapter outlines the Thermostat User Interface (UI) Configuration cluster which is defined in the ZCL and provides an interface for configuring the user interface (keypad and/or LCD screen) of a thermostat - this interface may be located on a controlling device which is remote from the thermostat.

The Thermostat UI Configuration cluster has a Cluster ID of 0x0204.

Overview The Thermostat UI Configuration cluster is required in ZigBee devices as indicated in the table below.

	Server-side	Client-side
Mandatory in...		
Optional in...	Thermostat	Configuration Tool

Combined Interface

|

The Thermostat UI Configuration cluster is enabled by defining CLD_THERMOSTAT_UI_CONFIG in the **zcl_options.h** file.

The inclusion of the client or server software must be pre-defined in the application's compile-time options (in addition, if the cluster is to reside on a custom endpoint then the role of client or server must also be specified when creating the cluster instance).

The compile-time options for the Thermostat UI Configuration cluster are fully detailed in Section 35.7.

Parent topic:*Thermostat UI Configuration Cluster*

Cluster structure and attributes The Thermostat UI Configuration cluster is contained in the following tsCLD_ThermostatUIConfig structure:

```
typedef struct
{
#ifdef THERMOSTAT_UI_CONFIG_SERVER
    zenum8          eTemperatureDisplayMode;
    zenum8          eKeypadLockout;
#endif
    zuint16         u16ClusterRevision;
} tsCLD_ThermostatUIConfig;;
```

where:

- eTemperatureDisplayMode specifies the units (Celsius or Fahrenheit) used to display temperature on the screen of the user interface. Enumerations are provided:
  - E_CLD_THERMOSTAT_UI_CONFIG_TEMPERATURE_DISPLAY_MODE_CELSIUS
  - E_CLD_THERMOSTAT_UI_CONFIG_TEMPERATURE_DISPLAY_MODE_FAHRENHEIT
- eKeypadLockout specifies the level of functionality that is available via the keypad of the user interface. Enumerations are provided:
  - E_CLD_THERMOSTAT_UI_CONFIG_KEYPAD_LOCKOUT_NO_LOCKOUT
  - E_CLD_THERMOSTAT_UI_CONFIG_KEYPAD_LOCKOUT_LEVEL_1_LOCKOUT
  - E_CLD_THERMOSTAT_UI_CONFIG_KEYPAD_LOCKOUT_LEVEL_2_LOCKOUT
  - E_CLD_THERMOSTAT_UI_CONFIG_KEYPAD_LOCKOUT_LEVEL_3_LOCKOUT
  - E_CLD_THERMOSTAT_UI_CONFIG_KEYPAD_LOCKOUT_LEVEL_4_LOCKOUT
  - E_CLD_THERMOSTAT_UI_CONFIG_KEYPAD_LOCKOUT_LEVEL_5_LOCKOUT
    - The functionality of each level is manufacturer-defined but level 5 represents the minimum functionality.
- u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specification on which this cluster instance is based. The cluster specification in the ZCL r6 corresponds to a cluster revision of 1. The value is incremented by one for each subsequent revision of the cluster specification. This attribute is also described in Section 2.4.

Parent topic:*Thermostat UI Configuration Cluster*

Initialization The function **eCLD_ThermostatUIConfigCreateThermostatUIConfig()** is used to create an instance of the Thermostat UI Configuration cluster. The function is generally called by the initialization function for the host device.

Parent topic:*Thermostat UI Configuration Cluster*

Functions The following Thermostat UI Configuration cluster functions are provided:

- **Function Page**
- eCLD_ThermostatUIConfigCreateThermostatUIConfig 754
- eCLD_ThermostatUIConfigConvertTemp 756

eCLD_ThermostatUIConfigCreateThermostatUIConfig

```
teZCL_Status eCLD_ThermostatUIConfigCreateThermostatUIConfig(
    tsZCL_ClusterInstance *psClusterInstance,
    bool_t bIsServer,
    sZCL_ClusterDefinition *psClusterDefinition,
    void *pvEndPointSharedStructPtr,
    uint8 *pu8AttributeControlBits);
```

Description This function creates an instance of the Thermostat UI Configuration cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function will create a Thermostat UI Configuration cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions.

Note: This function must not be called for an endpoint on which a standard ZigBee device (for example, the Thermostat device) is used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function.

When used, this function must be the first Thermostat UI Configuration cluster function called in the application, and must be called after the stack has been started and after the ZCL has been initialized.

The function requires an array to be declared for internal use, which contains one element (of type uint8) for each attribute of the cluster. The array length should therefore equate to the total number of attributes supported by the Thermostat UI Configuration cluster.

The function initializes the array elements to zero.

Parameters

- *psClusterInstance*: Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initializing individual structure fields.
- *bIsServer* : Type of cluster instance (server or client) to be created:
- TRUE - server
- FALSE - client
- *psClusterDefinition*: Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the Thermostat UI Configuration cluster. This parameter can refer to a pre-filled structure called sCLD_``Thermostat``UIConfig which is provided in the **ThermostatUIConfig.h** file.
- *pvEndPointSharedStructPtr*: Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_``Thermostat``UIConfig which defines the attributes of Thermostat UI Configuration cluster. The function initializes the attributes with default values.
- *pu8AttributeControlBits*: Pointer to an array of **uint8** values, with one element for each attribute in the cluster (see above).

Returns

- E_ZCL_SUCCESS

- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_ThermostatUIConfigConvertTemp

```
teZCL_Status eCLD_ThermostatUIConfigConvertTemp(
    uint8 u8SourceEndPointId,
    bool bConvertCToF,
    int16 *pi16Temperature);
```

Description This function can be used on a Thermostat UI Configuration cluster server to convert a temperature from units of Celsius to Fahrenheit or vice-versa (the direction must be specified). The temperature value to be converted is provided to the function as a pointer to a memory location where the input value is stored. This stored value is replaced with the converted temperature value by the function (over-writing the input value).

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the Thermostat UI Configuration cluster resides
- *bConvertCToF*: Direction of temperature conversion:
- TRUE - Celsius to Fahrenheit
- FALSE - Fahrenheit to Celsius
- *pi16Temperature*: Pointer to location containing the temperature value to be converted. The converted temperature value is also output to this location by the function

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_INVALID_VALUE
- E_ZCL_DENY_ATTRIBUTE_ACCESS
- E_ZCL_ERR_CLUSTER_NOT_FOUND

Parent topic: Functions

Parent topic:*Thermostat UI Configuration Cluster*

Return codes The Thermostat UI Configuration cluster functions use the ZCL return codes defined in Section 7.2.

Parent topic:*Thermostat UI Configuration Cluster*

Enumerations

'Attribute ID' Enumerations The following structure contains the enumerations used to identify the attributes of the Thermostat UI Configuration cluster.

```
typedef enum
{
  E_CLD_THERMOSTAT_UI_CONFIG_ATTR_ID_TEMPERATURE_DISPLAY_MODE = 0x0000
  E_CLD_THERMOSTAT_UI_CONFIG_ATTR_ID_KEYPAD_LOCKOUT
} teCLD_ThermostatUIConfig_AttributeID;
```

Parent topic: Enumerations

'Temperature Display Mode' Enumerations The following enumerations are used to set the optional attribute eTemperatureDisplayMode in the Thermostat UI Configuration cluster structure tsCLD_ThermostatUIConfig.

```
typedef enum
{
  E_CLD_THERMOSTAT_UI_CONFIG_TEMPERATURE_DISPLAY_MODE_CELSIUS = 0x00,
  E_CLD_THERMOSTAT_UI_CONFIG_TEMPERATURE_DISPLAY_MODE_FAHRENHEIT
} teCLD_ThermostatUIConfig_TemperatureDisplay;
```

The above enumerations represent the units of temperature available to display temperature on the screen of the user interface and are described in the table below.

Enumeration	Description
E_CLD_THERMOSTAT_UI_CONFIG_TEMPERATURE_DISPLAY_MO	Display temperature in Celsius
E_CLD_THERMOSTAT_UI_CONFIG_TEMPERATURE_DISPLAY_MO	Display temperature in Fahrenheit

Parent topic: Enumerations

'Keypad Functionality' Enumerations The following enumeration is used to set the optional attribute eKeypadLockout in the Thermostat UI Configuration cluster structure tsCLD_ThermostatUIConfig.

```
typedef enum
{
    E_CLD_THERMOSTAT_UI_CONFIG_KEYPAD_LOCKOUT_NO_LOCKOUT = 0x00,
    E_CLD_THERMOSTAT_UI_CONFIG_KEYPAD_LOCKOUT_LEVEL_1_LOCKOUT,
    E_CLD_THERMOSTAT_UI_CONFIG_KEYPAD_LOCKOUT_LEVEL_2_LOCKOUT,
    E_CLD_THERMOSTAT_UI_CONFIG_KEYPAD_LOCKOUT_LEVEL_3_LOCKOUT,
    E_CLD_THERMOSTAT_UI_CONFIG_KEYPAD_LOCKOUT_LEVEL_4_LOCKOUT,
    E_CLD_THERMOSTAT_UI_CONFIG_KEYPAD_LOCKOUT_LEVEL_5_LOCKOUT
} teCLD_ThermostatUIConfig_KeyPadLockout;
```

The above enumerations represent levels of functionality available via the keypad of the user interface. The functionality of each level is manufacturer-defined but level 5 represents the minimum functionality.

Parent topic: Enumerations

Parent topic:*Thermostat UI Configuration Cluster*

Compile-time Options To enable the Thermostat UI Configuration cluster in the code to be built, it is necessary to add the following to the **zcl_options.h** file:

```
#define CLD_THERMOSTAT_UI_CONFIG
```

In addition, to include the software for a cluster client or server or both, it is necessary to add one or both of the following to the same file:

```
#define THERMOSTAT_UI_CONFIG_SERVER
#define THERMOSTAT_UI_CONFIG_CLIENT
```

Add this line to define the value (n) of the Cluster Revision attribute:

```
#define CLD_THERMOSTAT_UI_CONFIG_CLUSTER_REVISION <n>
```

The default value is 1, which corresponds to the revision of the cluster in the ZCL r6 specification (see Section 2.4).

Parent topic:*Thermostat UI Configuration Cluster*

Part VII: Closure Clusters This part comprises one chapter:

- *Chapter 36* details the **Door Lock** cluster

Door Lock Cluster This chapter outlines the Door Lock cluster, which provides an interface to a set values representing the state of a door lock and (optionally) the door.

The Door Lock cluster has a Cluster ID of 0x0101.

Overview The Door Lock cluster is required in ZigBee devices as indicated in the table below.

	Server-side	Client-side
Mandatory in...	Door Lock	Door Lock Controller
Optional in...		Remote Control

The Door Lock cluster is enabled by defining CLD_DOOR_LOCK in the **zcl_options.h** file.

The inclusion of the client or server software must be pre-defined in the application's compile-time options (in addition, if the cluster is to reside on a custom endpoint then the role of client or server must also be specified when creating the cluster instance).

The compile-time options for the Door Lock cluster are fully detailed in Section 36.9.

Parent topic:*Door Lock Cluster*

Door Lock Cluster structure and attributes The Door Lock cluster is contained in the following ts``CLD_DoorLock structure:

```
typedef struct
{
#ifdef DOOR_LOCK_SERVER
    zenum8                  eLockState;
```

(continues on next page)

(continued from previous page)

```
    zenum8                  eLockType;
    zbool                   bActuatorEnabled;
#ifdef CLD_DOOR_LOCK_ATTR_DOOR_STATE
    zenum8                  eDoorState;
#endif
#ifdef CLD_DOOR_LOCK_ATTR_NUMBER_OF_DOOR_OPEN_EVENTS
    zuint32                 u32NumberOfDoorOpenEvent;
#endif
#ifdef CLD_DOOR_LOCK_ATTR_NUMBER_OF_DOOR_CLOSED_EVENTS
    zuint32                 u32NumberOfDoorClosedEvent;
#endif
#ifdef CLD_DOOR_LOCK_ATTR_NUMBER_OF_MINUTES_DOOR_OPENED
    zuint16                 u16NumberOfMinutesDoorOpened;
#endif
#ifdef CLD_DOOR_LOCK_ZIGBEE_SECUTRITY_LEVEL
    zuint8                  u8ZigbeeSecurityLevel;
#endif
#ifdef CLD_DOOR_LOCK_ATTRIBUTE_REPORTING_STATUS
    zuint8                  u8AttributeReportingStatus;
#endif
#endif
    zuint16                 u16ClusterRevision;
} tsCLD_DoorLock;
```

where:

- eLockState is a mandatory attribute indicating the state of the lock, one of:
  - E_CLD_DOORLOCK_LOCK_STATE_NOT_FULLY_LOCKED
  - E_CLD_DOORLOCK_LOCK_STATE_LOCK
  - E_CLD_DOORLOCK_LOCK_STATE_UNLOCK
- eLockType is a mandatory attribute representing the type of door lock, one of:
  - E_CLD_DOORLOCK_LOCK_TYPE_DEAD_BOLT
  - E_CLD_DOORLOCK_LOCK_TYPE_MAGNETIC
  - E_CLD_DOORLOCK_LOCK_TYPE_OTHER
  - E_CLD_DOORLOCK_LOCK_TYPE_MORTISE
  - E_CLD_DOORLOCK_LOCK_TYPE_RIM
  - E_CLD_DOORLOCK_LOCK_TYPE_LATCH_BOLT
  - E_CLD_DOORLOCK_LOCK_TYPE_CYLINDRICAL_LOCK
  - E_CLD_DOORLOCK_LOCK_TYPE_TUBULAR_LOCK
  - E_CLD_DOORLOCK_LOCK_TYPE_INTERCONNECTED_LOCK
  - E_CLD_DOORLOCK_LOCK_TYPE_DEAD_LATCH
  - E_CLD_DOORLOCK_LOCK_TYPE_DOOR_FURNITURE
- bActuatorEnabled is a mandatory attribute indicating whether the actuator for the door lock is enabled:
  - TRUE - enabled
  - FALSE - disabled
- eDoorState is an optional attribute indicating the current state of the door, one of:
  - E_CLD_DOORLOCK_DOOR_STATE_OPEN

  - E_CLD_DOORLOCK_DOOR_STATE_CLOSED
  - E_CLD_DOORLOCK_DOOR_STATE_ERROR_JAMMED
  - E_CLD_DOORLOCK_DOOR_STATE_ERROR_FORCED_OPEN
  - E_CLD_DOORLOCK_DOOR_STATE_ERROR_UNSPECIFIED
- u32NumberOfDoorOpenEvent is an optional attribute representing the number of 'door open' events that have occurred
- u32NumberOfDoorClosedEvent is an optional attribute representing the number of 'door close' events that have occurred
- u16NumberOfMinutesDoorOpened is an optional attribute representing the length of time, in minutes, that the door has been open since the last 'door open' event
- u8ZigbeeSecurityLevel is an optional attribute representing the ZigBee PRO security level that should be applied to communications between a cluster server and client:
  - 0: Network-level security only
  - 1 or higher: Application-level security (in addition to Network-level security)
    * Application-level security is an enhancement to the Door Lock cluster and is currently not certifiable.

Note: The application must not write directly to the u8ZigbeeSecurityLevel attribute. If required, Application-level security should be enabled only using the function **eCLD_DoorLockSetSecurityLevel()**. For more information, refer to the description of this function on page 771.

u8AttributeReportingStatus is an optional attribute that should be enabled when attribute reporting is used for the cluster (see [Section 2.3.5](../../ZCL_fundamentals/topics/attribute_reporting.md#id_d3e2d682-d5e6-4aa5-870f-4d2e0320637e)). The value of this attribute indicates whether there are attribute reports still pending (0x00) or the attribute reports are complete (0x01) - all other values are reserved. This attribute is also described in [Section 2.4](../../ZCL_fundamentals/topics/global_attributes.md#id_8f80e769-8ccd-4b4f-8609-579f4457d527).
u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specification on which this cluster instance is based. The cluster specification in the ZCL r6 corresponds to a cluster revision of 1. The value is incremented by one for each subsequent revision of the cluster specification. This attribute is also described in [Section 2.4](../../ZCL_fundamentals/topics/global_attributes.md#id_8f80e769-8ccd-4b4f-8609-579f4457d527).

Parent topic:*Door Lock Cluster*

Attributes for Default Reporting The following attributes of the Door Lock cluster can be selected for default reporting:

eLockState
eDoorState

Attribute reporting (including default reporting) is described in *Appendix B.* Enabling reports for these attributes is described in Appendix B.3.6.

Parent topic:*Door Lock Cluster*

Door Lock Events The Door Lock cluster has its own events that are handled through the callback mechanism outlined in *Chapter 3*. If a device uses the Door Lock cluster then Door Lock event handling must be included in the callback function for the associated endpoint, where this

callback function is registered through the relevant endpoint registration function (for example, through **eHA_RegisterDoorLockEndPoint()** for a Door Lock device). The relevant callback function will then be invoked when a Door Lock event occurs.

For a Door Lock event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsCLD_DoorLockCallBackMessage structure:

```
typedef struct
{
    uint8    u8CommandId;
    union
    {
      tsCLD_DoorLock_LockUnlockResponsePayload *psLockUnlockResponsePayload;
    }uMessage;
 }tsCLD_DoorLockCallBackMessage;
```

When a Door Lock event occurs, one of two command types could have been received. The relevant command type is specified through the u8CommandId field of the tsCLD_DoorLockCallBackMessage structure. The possible command types are detailed below.

u8CommandId Enumeration	Description
E_CLD_DOOR_LOCK_CMD_LOCK	A lock request command has been received by the clus-ter server
E_CLD_DOOR_LOCK_CMD_UNLC	An unlock request command has been received by the clus-ter server

Parent topic:*Door Lock Cluster*

Functions The following Door Lock cluster functions are provided:

- **Function Page**
- eCLD_DoorLockCreateDoorLock 766
- eCLD_DoorLockSetLockState 768
- eCLD_DoorLockGetLockState 769
- eCLD_DoorLockCommandLockUnlockRequestSend 770
- eCLD_DoorLockSetSecurityLevel 771

eCLD_DoorLockCreateDoorLock

```
teZCL_Status eCLD_DoorLockCreateDoorLock(
    tsZCL_ClusterInstance *psClusterInstance,
    bool_t bIsServer,
    tsZCL_ClusterDefinition *psClusterDefinition,
    void *pvEndPointSharedStructPtr,
    uint8 *pu8AttributeControlBits);
```

Description This function creates an instance of the Door Lock cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function will create a Door Lock cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions.

Note: This function must not be called for an endpoint on which a standard ZigBee device (e.g. the Door Lock device) will be used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function.

When used, this function must be the first Door Lock cluster function called in the application, and must be called after the stack has been started and after the ZCL has been initialized.

The function requires an array to be declared for internal use, which contains one element (of type uint8) for each attribute of the cluster. The array length should therefore equate to the total number of attributes supported by the Door Lock cluster.

The function initializes the array elements to zero.

Parameters

- **psClusterInstance*: Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initialising individual structure fields.
- *bIsServer*: Type of cluster instance (server or client) to be created:
- TRUE - server
- FALSE - client
- **psClusterDefinition*: Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the Door Lock cluster. This parameter can refer to a pre-filled structure called sCLD_DoorLock which is provided in the **DoorLock.h** file.
- **pvEndPointSharedStructPtr*: Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_DoorLock which defines the attributes of Door Lock cluster. The function initializes the attributes with default values.
- **pu8AttributeControlBits* : Pointer to an array of **uint8** values, with one element for each attribute in the cluster (see above).

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_DoorLockSetLockState

```
teZCL_Status eCLD_DoorLockSetLockState(
    uint8 u8SourceEndPointId,
    teCLD_DoorLock_LockState eLock);
```

Description This function can be used on a Door Lock cluster server to set the value of the eLockState attribute which represents the current state of the door lock (locked, unlocked or not fully locked).

Depending on the specified value of *eLock*, the attribute will be set to one of the following:

- E_CLD_DOORLOCK_LOCK_STATE_NOT_FULLY_LOCKED
- E_CLD_DOORLOCK_LOCK_STATE_LOCK
- E_CLD_DOORLOCK_LOCK_STATE_UNLOCK

This function generates an update event to inform the application when the change has been made.

Parameters

- *u8SourceEndPointId* Number of the endpoint on which the Door Lock cluster resides
- *eLock* State in which to put the door lock, one of:
- E_CLD_DOORLOCK_LOCK_STATE_NOT_FULLY_LOCKED
- E_CLD_DOORLOCK_LOCK_STATE_LOCK
- E_CLD_DOORLOCK_LOCK_STATE_UNLOCK

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Functions

eCLD_DoorLockGetLockState

```
teZCL_Status eCLD_DoorLockGetLockState(
    uint8 u8SourceEndPointId,
    teCLD_DoorLock_LockState *peLock);
```

Description This function can be used on a Door Lock cluster server to obtain the value of the eLockState attribute which represents the current state of the door lock (locked, unlocked or not fully locked).

The value of the attribute is returned through the location pointed to by peLock and can be any one of the following:

- E_CLD_DOORLOCK_LOCK_STATE_NOT_FULLY_LOCKED
- E_CLD_DOORLOCK_LOCK_STATE_LOCK
- E_CLD_DOORLOCK_LOCK_STATE_UNLOCK

Parameters

- *u8SourceEndPointId* Number of the endpoint on which the Door Lock cluster resides
- *peLock* Pointer to location to receive the obtained state of the door lock, which will be one of:
- E_CLD_DOORLOCK_LOCK_STATE_NOT_FULLY_LOCKED

- E_CLD_DOORLOCK_LOCK_STATE_LOCK
- E_CLD_DOORLOCK_LOCK_STATE_UNLOCK

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Functions

eCLD_DoorLockCommandLockUnlockRequestSend

```
teZCL_Status eCLD_DoorLockCommandLockUnlockRequestSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    teCLD_DoorLock_CommandID eCommand);
```

Description This function can be used on a Door Lock cluster client to send a lock or unlock command to the Door Lock cluster server.

A pointer must be specified to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which the request is sent
- *u8DestinationEndPointId* Number of the remote endpoint to which the request is sent
- *psDestinationAddress* Pointer to a structure containing the address of the remote node to which the request is sent
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the request
- *eCommand* The command to be sent, one of:
- E_CLD_DOOR_LOCK_CMD_LOCK
- E_CLD_DOOR_LOCK_CMD_UNLOCK

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

Parent topic: Functions

eCLD_DoorLockSetSecurityLevel

```
teZCL_Status eCLD_DoorLockSetSecurityLevel(
    uint8 u8SourceEndPointId,
    bool bServer,
    uint8 u8SecurityLevel);
```

Description This function can be used to set the level of security to be used by the Door Lock cluster: Network-level security or Application-level security. By default, only Network-level security is implemented, but this function can be used to enable Application-level security (in addition to Network-level security). For more information on ZigBee security, refer to the *ZigBee 3.0 Stack User Guide (JNUG3130)*.

Application-level security is an enhancement to the Door Lock cluster and is currently not certifiable. It is enabled through an optional attribute of the cluster, but the application must not write directly to this attribute - if required, Application-level security should be enabled only using this function.

To use Application-level security, it is necessary to call this function on the Door Lock cluster server and client nodes. If an application link key is to be used which is not the default one, the new link key must be subsequently specified on both nodes using the ZigBee PRO function **ZPS_eAplZdoAddReplaceLinkKey()**.

Parameters

- *u8SourceEndPointId* Number of the local endpoint on which the Door Lock cluster resides
- *bIsServer* Type of local cluster instance (server or client):
- TRUE - server
- FALSE - client
- *u8SecurityLevel* The security level to be set:
- 0: Network-level security only
- 1 or higher: Application-level security

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Return codes The Door Lock cluster functions use the ZCL return codes defined in Section 7.2.

Parent topic:*Door Lock Cluster*

Enumerations

'Attribute ID' Enumerations The following structure contains the enumerations used to identify the attributes of the Door Lock cluster.

```
typedef enum
{
    E_CLD_DOOR_LOCK_ATTR_ID_LOCK_STATE = 0x0000,
    E_CLD_DOOR_LOCK_ATTR_ID_LOCK_TYPE,
    E_CLD_DOOR_LOCK_ATTR_ID_ACTUATOR_ENABLED,
    E_CLD_DOOR_LOCK_ATTR_ID_DOOR_STATE,
    E_CLD_DOOR_LOCK_ATTR_ID_NUMBER_OF_DOOR_OPEN_EVENTS,
    E_CLD_DOOR_LOCK_ATTR_ID_NUMBER_OF_DOOR_CLOSED_EVENTS,
    E_CLD_DOOR_LOCK_ATTR_ID_NUMBER_OF_MINUTES_DOOR_OPENED,
    E_CLD_DOOR_LOCK_ATTR_ID_ZIGBEE_SECURITY_LEVEL = 0x0034
} teCLD_DoorLock_Cluster_AttrID;
```

Parent topic: Enumerations

'Lock State' Enumerations The following enumerations are used to set the eLockState element in the Door Lock cluster structure tsCLD_DoorLock.

```
typedef enum
{
    E_CLD_DOORLOCK_LOCK_STATE_NOT_FULLY_LOCKED  = 0x00,
    E_CLD_DOORLOCK_LOCK_STATE_LOCKED,
    E_CLD_DOORLOCK_LOCK_STATE_UNLOCKED,
    E_CLD_DOORLOCK_LOCK_STATE_UNDEFINED         = 0xFF
} teCLD_DoorLock_LockState;
```

The above enumerations are described in the table below.

Enumeration	Description
E_CLD_DOORLOCK_LOCK_STATE_NOT_FULLY_LOCKED	Not fully locked
E_CLD_DOORLOCK_LOCK_STATE_LOCK	Locked
E_CLD_DOORLOCK_LOCK_STATE_UNLOCK	Unlocked

Parent topic: Enumerations

'Lock Type' Enumerations The following enumerations are used to set the eLockType element in the Door Lock cluster structure tsCLD_DoorLock.

```
typedef enum
{
    E_CLD_DOORLOCK_LOCK_TYPE_DEAD_BOLT  = 0x00,
    E_CLD_DOORLOCK_LOCK_TYPE_MAGNETIC,
    E_CLD_DOORLOCK_LOCK_TYPE_OTHER,
    E_CLD_DOORLOCK_LOCK_TYPE_MORTISE,
    E_CLD_DOORLOCK_LOCK_TYPE_RIM,
    E_CLD_DOORLOCK_LOCK_TYPE_LATCH_BOLT,
    E_CLD_DOORLOCK_LOCK_TYPE_CYLINDRICAL_LOCK,
    E_CLD_DOORLOCK_LOCK_TYPE_TUBULAR_LOCK,
    E_CLD_DOORLOCK_LOCK_TYPE_INTERCONNECTED_LOCK,
    E_CLD_DOORLOCK_LOCK_TYPE_DEAD_LATCH,
    E_CLD_DOORLOCK_LOCK_TYPE_DOOR_FURNITURE
} teCLD_DoorLock_LockType;
```

The above enumerations are described in the table below.

Enumeration	Description
E_CLD_DOORLOCK_LOCK_TYPE_DEAD_BOLT	Dead bold lock
E_CLD_DOORLOCK_LOCK_TYPE_MAGNETIC	Magnetic lock
E_CLD_DOORLOCK_LOCK_TYPE_OTHER	Other type of lock
E_CLD_DOORLOCK_LOCK_TYPE_MORTISE	Mortise lock
E_CLD_DOORLOCK_LOCK_TYPE_RIM	Rim lock
E_CLD_DOORLOCK_LOCK_TYPE_LATCH_BOLT	Latch bolt
E_CLD_DOORLOCK_LOCK_TYPE_CYLINDRICAL_LOCK	Cylindrical lock
E_CLD_DOORLOCK_LOCK_TYPE_TUBULAR_LOCK	Tubular lock
E_CLD_DOORLOCK_LOCK_TYPE_INTERCONNECTED_LOCK	Interconnected lock
E_CLD_DOORLOCK_LOCK_TYPE_DEAD_LATCH	Dead latch
E_CLD_DOORLOCK_LOCK_TYPE_DOOR_FURNITURE	Door furniture lock

Parent topic: Enumerations

'Door State' Enumerations The following enumerations are used to set the optional eDoorState element in the Door Lock cluster structure tsCLD_DoorLock.

```
typedef enum
{
    E_CLD_DOORLOCK_DOOR_STATE_OPEN  = 0x00,
    E_CLD_DOORLOCK_DOOR_STATE_CLOSED,
    E_CLD_DOORLOCK_DOOR_STATE_ERROR_JAMMED,
    E_CLD_DOORLOCK_DOOR_STATE_ERROR_FORCED_OPEN,
    E_CLD_DOORLOCK_DOOR_STATE_ERROR_UNSPECIFIED,
    E_CLD_DOORLOCK_DOOR_STATE_UNDEFINED = 0xFF
} teCLD_DoorLock_DoorState;;
```

The above enumerations are described in the table below.

Enumeration	Description
E_CLD_DOORLOCK_DOOR_STATE_OPEN	Door is open
E_CLD_DOORLOCK_DOOR_STATE_CLOSED	Door is closed
E_CLD_DOORLOCK_DOOR_STATE_ERROR_JAMMED	Door is jammed
E_CLD_DOORLOCK_DOOR_STATE_ERROR_FORCED_OPEN	Door has been forced open
E_CLD_DOORLOCK_DOOR_STATE_ERROR_UNSPECIFIED	Door is in an unknown state

Parent topic: Enumerations

'Command ID' Enumerations The following enumerations are used to set specify the type of command (lock or unlock) sent to a Door Lock cluster server.

```
typedef enum
{
    E_CLD_DOOR_LOCK_CMD_LOCK
    E_CLD_DOOR_LOCK_CMD_UNLOCK
} teCLD_DoorLock_CommandID;
```

The above enumerations are described in the table below.

Enumeration	Description
E_CLD_DOOR_LOCK_CMD_LOCK	A lock command
E_CLD_DOOR_LOCK_CMD_UNLOCK	An unlock command

Parent topic: Enumerations

Parent topic:*Door Lock Cluster*

Structures

tsCLD_DoorLockCallBackMessage For a Door Lock event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsCLD_DoorLockCallBackMessage structure:

```
typedef struct
{
    uint8 u8CommandId;
    union
    {
      tsCLD_DoorLock_LockUnlockResponsePayload *psLockUnlockResponsePayload;
    }uMessage;
 }tsCLD_DoorLockCallBackMessage;
```

where:

- u``8CommandId indicates the type of Door Lock command (lock or unlock) that has been received, one of:
  - E_CLD_DOOR_LOCK_CMD_LOCK
  - E_CLD_DOOR_LOCK_CMD_UNLOCK
- uMessage is a union containing the command payload in the following form:
  - psLockUnlockResponsePayload is a pointer to a structure containing the response payload of the received command - see Section 36.8.2

Parent topic: Structures

tsCLD_DoorLock_LockUnlockResponsePayload This stucture contains the payload of a lock/unlock command response (from the cluster server).

```
typedef struct
{
    zenum8      eStatus;
}tsCLD_DoorLock_LockUnlockResponsePayload;
```

where e``Status indicates whether the command was received:

0x00 - SUCCESS, 0x01 - FAILURE (all other values are reserved).

Parent topic: Structures

Parent topic:*Door Lock Cluster*

Compile-time options To enable the Door Lock cluster in the code to be built, it is necessary to add the following to the **zcl_options.h** file:

```
#define CLD_DOOR_LOCK
```

In addition, to include the software for a cluster client or server or both, it is necessary to add one or both of the following to the same file:

```
#define CLD_DOOR_LOCK_SERVER
#define CLD_DOOR_LOCK_CLIENT
```

Optional Attributes Add this line to enable the optional Door State attribute:

```
#define CLD_DOOR_LOCK_ATTR_DOOR_STATE
```

Add this line to enable the optional Number Of Door Open Events attribute:

```
#define CLD_DOOR_LOCK_ATTR_NUMBER_OF_DOOR_OPEN_EVENTS
```

Add this line to enable the optional Number Of Door Closed Events attribute:

```
#define CLD_DOOR_LOCK_ATTR_NUMBER_OF_DOOR_CLOSED_EVENTS
```

Add this line to enable the optional Number Of Minutes Door Opened attribute:

```
#define CLD_DOOR_LOCK_ATTR_NUMBER_OF_MINUTES_DOOR_OPENED
```

Add this line to enable the optional ZigBee Security Level attribute:

```
#define CLD_DOOR_LOCK_ZIGBEE_SECURITY_LEVEL
```

Add this line to enable the optional Attribute Reporting Status attribute:

```
#define CLD_DOOR_LOCK_ATTR_ID_ATTRIBUTE_REPORTING_STATUS
```

Global Attributes Add this line to define the value (n) of the Cluster Revision attribute:

```
#define CLD_DOOR_LOCK_CLUSTER_REVISION <n>
```

The default value is 1, which corresponds to the revision of the cluster in the ZCL r6 specification (see Section 2.4).

Parent topic:*Door Lock Cluster*

Part VIII: Security and Safety Clusters This part comprises three chapters:

- *Chapter 37* details the **IAS Zone** cluster
- *Chapter 38* details the **IAS ACE (Ancillary Control Equipment)** cluster
- *Chapter 39* details the **IAS WD (Warning Device)** cluster

IAS Zone Cluster This chapter describes the IAS Zone cluster which provides an interface to an IAS Zone device in an IAS (Intruder Alarm System).

The IAS Zone cluster has a Cluster ID of 0x0500.

Overview The IAS Zone cluster provides an interface to an IAS Zone device, which provides security alarm triggers for a zone or region of a building (e.g. fire detection). The cluster allows an IAS Zone device to be configured/controlled from a CIE (Control and Indicating Equipment) device. The server side of the cluster is implemented on the IAS Zone device and the client side is implemented on the CIE device. The IAS Zone device is detailed in the *ZigBee Devices User Guide (JNUG3131)*.

The cluster supports the following functionality:

- Up to two alarm types per zone, Alarm1 and Alarm2
- 'Low battery' reports
- Supervision of the IAS network

To use the functionality of this cluster, you must include the file **IASZone.h** in your application and enable the cluster by defining CLD_IASZONE in the **zcl_options.h** file.

The inclusion of the client or server software must be pre-defined in the application's compile-time options (in addition, if the cluster is to reside on a custom endpoint then the role of client or server must also be specified when creating the cluster instance).

The compile-time options for the IAS Zone cluster are fully detailed in Section 37.7.

The information that can potentially be stored in this cluster is organised into the following attribute sets:

- Zone information
- Zone settings

Parent topic:*IAS Zone Cluster*

IAS Zone Structure and Attributes The structure definition for the IAS Zone cluster is:

```
typedef struct
{
#ifdef IASZONE_SERVER
    zenum8      e8ZoneState;
    zenum16     e16ZoneType;
    zbmap16     b16ZoneStatus;
    zuint64     u64IASCIEAddress;
    zuint8      u8ZoneId;
#ifdef CLD_IASZONE_ATTR_ID_NUMBER_OF_ZONE_SENSITIVITY_LEVELS
    zuint8      u8NumberOfZoneSensitivityLevels;
#endif
#ifdef CLD_IASZONE_ATTR_ID_CURRENT_ZONE_SENSITIVITY_LEVEL
    zuint8      u8CurrentZoneSensitivityLevel;
#endif
#endif
    zuint16     u16ClusterRevision;
} tsCLD_IASZone;
```

where:

'Zone Information' Attribute Set

- e8ZoneState is a mandatory attribute which indicates the membership status of the device in an IAS system (enrolled or not enrolled) - one of:
  - E_CLD_IASZONE_STATE_NOT_ENROLLED (0x00)
  - E_CLD_IASZONE_STATE_ENROLLED (0x01)
    - 'Enrolled' means that the cluster client will react to Zone State Change Notification commands from the cluster server.
- e16ZoneType is a mandatory attribute which indicates the zone type and the types of security detectors that can trigger the alarms, Alarm1 and Alarm2:

Enumeration	Value	Type	Alarm1	Alarm2
E_CLD_IASZONE_TYPE_STANDARI	0x00(	Standard CIE	System alarm	-
E_CLD_IASZONE_TYPE_MOTION _ SENSOR	0x00(	Motion sensor	Intrusion indication	Presence indica- tion
E_CLD_IASZONE_TYPE_CONTACT _ SWITCH	0x001	Contact switch	First portal open close	Second portal open-close
E_CLD_IASZONE_TYPE_FIRE_SENS	0x002	Fire sensor	Fire indication	-
E_CLD_IASZONE_TYPE_WATER_SE	0x002	Water sensor	Water overflow indication	-
E_CLD_IASZONE_TYPE_GAS_SENS	0x002	Gas sensor	Carbon monoxide indication	Cooking indica- tion
E_CLD_IASZONE_TYPE_PERSONAI _ EMERGENCY_DEVICE	0x002	Personal emergency device	Fall/concussion	Emergency but- ton
E_CLD_IASZONE_TYPE_VIBRATIOI _ MOVEMENT_SENSOR	0x002	Vibration movement sensor	Movement indication	Vibration
E_CLD_IASZONE_TYPE_REMOTE _ CONTROL	0x01(	Remote control	Panic	Emergency
E_CLD_IASZONE_TYPE_KEY_FOB	0x011	Key fob	Panic	Emergency
E_CLD_IASZONE_TYPE_KEYPAD	0x021	Keypad	Panic	Emergency
E_CLD_IASZONE_TYPE_STANDARI _ WARNING_DEVICE	0x022	Standard warning device	-	-
E_CLD_IASZONE_TYPE_INVALID_2	0xFFI	Invalid zone type	-	-

- b``16ZoneStatus is a mandatory attribute which is a 16-bit bitmap indicating the status of each of the possible notification triggers from the device:

Bit	Description
0	Alarm1:1 - Opened or alarmed0 - Closed or not alarned
1	Alarm2:1 - Opened or alarmed0 - Closed or not alarned
2	Tamper:1 - Tampered with0 - Not tampered with
3	Battery:1 - Low0 - OK
4	Supervision reports: 1 - Reports0 - No reports (See the note below)
5	Restore reports: 1 - Reports0 - No reports (See the note below)
6	Trouble:1 - Trouble/failure0 - OK
7	AC (mains): 1 - Fault0 - OK
8	Test mode:1 - Sensor in test mode0 - Sensor in operational mode
9	Battery defect: 1 - Defective battery detected0 - Battery OK
10-15	Reserved

- Bit 4 indicates whether the Zone device issues periodic Zone Status Change Notification commands that may be used by the CIE device as evidence that the Zone device is operational.

- Bit 5 indicates whether the Zone device issues a Zone Status Change Notification command to notify when an alarm is no longer present (some Zone devices do not have the ability to detect when the alarm condition has disappeared).

'Zone Settings' Attribute Set

- u64IASCIEAddress is a mandatory attribute containing the 64-bit IEEE/MAC address of the CIE device to which the cluster server must send commands/ notifications
- u8ZoneId is a mandatory attribute containing the 8-bit identifier for the zone allocated by the CIE device at the time of enrollment
- u8NumberOfZoneSensitivityLevels is an optional attribute containing the number of sensitivity levels (for the detectable quantity) for the zone - for devices that have only one sensitivity level, this attribute need not be enabled or can be set to 0x00 or 0x01

  Note: The definition of a sensitivity level is manufacturer-specific but detector 'sensitivity' should increase with higher values of this attribute.
- u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specification on which this cluster instance is based. The cluster specification in the ZCL r6 corresponds to a cluster revision of 1. The value is incremented by one for each subsequent revision of the cluster specification. This attribute is also described in Section 2.4

Parent topic:*IAS Zone Cluster*

Enrollment An IAS Zone device hosting the IAS Zone cluster server must be paired with a CIE device hosting the cluster client. This pairing is implemented by the process of 'enrollment' which, for extra security, provides a layer of pairing in addition to ZigBee PRO binding - if required, binding is implemented as part of the enrollment process.

During enrollment, the CIE device sends its IEEE/MAC address to the Zone device as well as a Zone ID, which is a unique 8-bit identifier that the CIE device assigns to the Zone device. These values are stored in the u64IASCIEAddress and u8ZoneId attributes on the Zone device (cluster server) - see Section 37.2. In addition, once enrollment has completed, the e8ZoneState attribute is set to 'enrolled'. Subsequently, the Zone device will only communicate with the paired CIE device.

Enrollment begins just after the Zone device joins the network. This device must then periodically poll for data (from the CIE device), ideally once every 2 seconds (or faster) but no slower than once every 7 seconds. This polling must continue until the e8ZoneState attribute has been updated to 'enrolled'. However, if the IAS Zone device supports the Poll Control cluster, polling at the above rate should continue until the Poll Control cluster configuration is changed.

Three methods of enrollment are available:

- Trip-to-Pair, described in Section 37.3.1
- Auto-Enroll-Response, described in Section 37.3.2
- Auto-Enroll-Request, described in Section 37.3.3

A cluster server and client can each implement both Trip-to-Pair and Auto-Enroll-Response or just Auto-Enroll-Request.

Trip-to-Pair The Trip-to-Pair method of enrollment is described below:

1. After the IAS Zone device joins the network, the CIE device performs a service discovery.
2. If the CIE device determines that it wants to enroll the Zone device, it sends a Write Attribute command to the Zone device in order to write its IEEE/MAC address to the relevant attribute.

3. The Zone device may optionally create a binding table entry for the CIE device and store the CIE device's IEEE/MAC address there.
4. The Zone device waits for the authorization of the enrollment via a user input (for example, a button-press) and, on this input, sends a Zone Enroll Request command to the CIE device.
5. The CIE device assigns a Zone ID to the Zone device and sends a Zone Enroll Response command to it.
6. The Zone device updates its attributes to stored the assigned Zone ID and update its zone state to 'enrolled'.

Parent topic: Enrollment

Auto-Enroll-Response The Auto-Enroll-Response method of enrollment is described below:

1. After the IAS Zone device joins the network, the CIE device performs a service discovery.
2. If the CIE device determines that it wants to enroll the Zone device, it sends a Write Attribute command to the Zone device in order to write its IEEE/MAC address to the relevant attribute.
3. The Zone device may optionally create a binding table entry for the CIE device and store the CIE device's IEEE/MAC address there.
4. The CIE device assigns a Zone ID to the Zone device and sends a Zone Enroll Response command to it.
5. The Zone device updates its attributes to stored the assigned Zone ID and update its zone state to 'enrolled'.

Note: The above Auto-Enroll-Response process is similar to the Trip-to-Pair process (described in *Section 37.3.2*) except user authorization for the enrollment of the Zone device is not required and no Zone Enroll Request command needs to be sent to the CIE device.

Parent topic: Enrollment

Auto-Enroll-Request The Auto-Enroll-Request method of enrollment is described below:

1. After the IAS Zone device joins the network, the CIE device performs a service discovery.
2. If the CIE device determines that it wants to enroll the Zone device, it sends a Write Attribute command to the Zone device in order to write its IEEE/MAC address to the relevant attribute.
3. The Zone device may optionally create a binding table entry for the CIE device and store the CIE device's IEEE/MAC address there.
4. The Zone device sends a Zone Enroll Request command to the CIE device.
5. The CIE device assigns a Zone ID to the Zone device and sends a Zone Enroll Response command to it.
6. The Zone device updates its attributes to stored the assigned Zone ID and update its zone state to 'enrolled'.

Note: The above Auto-Enroll-Request process is similar to the Trip-to-Pair process (described in Section 37.3.2) except that user authorization for the enrollment of the Zone device is not required.

Parent topic: Enrollment

Parent topic:*IAS Zone Cluster*

IAS Zone Events The IAS Zone cluster has its own events that are handled through the callback mechanism outlined in *Chapter 3*. If a device uses the IAS Zone cluster then IAS Zone event handling must be included in the callback function for the associated endpoint, where this callback function is registered through the relevant endpoint registration function (for example, through **eHA_RegisterIASZoneEndPoint()** for a Zone device). The relevant callback function is then invoked when an IAS Zone event occurs.

For an IAS Zone event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsCLD_IASZoneCallBackMessage structure:

```
typedef struct
{
uint8 u8CommandId;
union
    {
     tsCLD_IASZone_TestModeUpdate                *psTestModeUpdate; /* Internal */
     tsCLD_IASZone_EnrollRequestCallBackPayload   sZoneEnrollRequestCallbackPayload;
     tsCLD_IASZone_EnrollResponsePayload          *psZoneEnrollResponsePayload;
     tsCLD_IASZone_StatusChangeNotificationPayload  *psZoneStatusNotificationPayload;
     tsCLD_IASZone_InitiateTestModeRequestPayload   *psZoneInitiateTestModeRequestPayload;
    } uMessage;
} tsCLD_IASZoneCallBackMessage;
```

When an IAS Zone event occurs, one of several command types could have been received. The relevant command type is specified through the u8CommandId field of the tsSM_CallBackMessage structure. The possible command/event types are detailed in the table below (note that psTestModeUpdate is for internal use only).

u8CommandId Enumeration	Description
E_CLD_IASZONE_CMD_ZONE_ENI	An IAS Zone Enroll Response has been received by the cluster server
E_CLD_IASZONE_CMD_ZONE_STA	An IAS Zone Status Change Notification has been received by the cluster client
E_CLD_IASZONE_CMD_ZONE_ENI	An IAS Zone Enroll Request has been received by the cluster client
E_CLD_IASZONE_CMD_INITIATE_	An IAS Zone Normal Operation Mode Initiation Request command has been received by the cluster server
E_CLD_IASZONE_CMD_INITIATE_	An IAS Zone Initiate Test Mode Request has been received by the cluster server

Parent topic:*IAS Zone Cluster*

Functions The following IAS Zone cluster functions are provided in the NXP implementation of the ZCL:

1. eCLD_IASZoneCreateIASZone
2. eCLD_IASZoneUpdateZoneStatus
3. eCLD_IASZoneUpdateZoneState
4. eCLD_IASZoneUpdateZoneType
5. eCLD_IASZoneUpdateZoneID
6. eCLD_IASZoneUpdateCIEAddress
7. eCLD_IASZoneEnrollReqSend
8. eCLD_IASZoneEnrollRespSend

9. eCLD_IASZoneStatusChangeNotificationSend
10. eCLD_IASZoneNormalOperationModeReqSend
11. eCLD_IASZoneTestModeReqSend

eCLD_IASZoneCreateIASZone

```
teZCL_Status eCLD_IASZoneCreateIASZone(
    tsZCL_ClusterInstance *psClusterInstance,
    bool_t bIsServer,
    tsZCL_ClusterDefinition *psClusterDefinition,
    void *pvEndPointSharedStructPtr,
    uint8 *pu8AttributeControlBits,
    tsCLD_IASZone_CustomDataStructure *psCustomDataStructure);
```

Description This function creates an instance of the IAS Zone cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function will create an IAS Zone cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions.

Note: This function must not be called for an endpoint on which a standard ZigBee device is used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function.

When used, this function must be called after the stack has been started and after the ZCL has been initialized.

Parameters

- *psClusterInstance*: Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initializing individual structure fields.
- *bIsServer* : Type of cluster instance (server or client) to be created: *TRUE - server FALSE - client*
- *psClusterDefinition*: Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the IAS Zone cluster. This parameter can refer to a pre-filled structure called sCLD_``IASZone which is provided in the **IASZone.h** file.
- *pvEndPointSharedStructPtr*: Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_IASZone which defines the attributes of IAS Zone cluster. The function initializes the attributes with default values.
- *pu8AttributeControlBits*: Pointer to an array of **uint8** values, with one element for each attribute in the cluster.
- *psCustomDataStructure*: Pointer to a structure containing the storage for internal functions of the cluster (see Section 37.6.1)

Returns

- E_ZCL_SUCCESS

- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_IASZoneUpdateZoneStatus

```
teZCL_Status eCLD_IASZoneUpdateZoneStatus(
    uint8 u8SourceEndPoint,
    uint16 u16StatusBitMask,
    bool_t bStatusState);
```

Description This function can be used on an IAS Zone cluster server to update the zone status bitmap stored in the b16ZoneStatus attribute, described in Section 37.2.

In one call to this function, one or more selected bits in the b16ZoneStatus attribute bitmap can be to set to '1' or '0'. The affected bits must themselves be specified in a bitmap and the value to be set must also be specified.

If the server is enrolled with a client on a CIE device, the function sends a notification of this update to the client, in a Zone Status Change Notification. Before sending the notification and returning, the function invokes a user-defined callback function to allow the application to validate the status change.

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the IAS Zone cluster resides
- *u16StatusBitMask*: 16-bit bitmap indicating the bits of the zb16ZoneStatus bitmap to be updated. There is a one-to-one correspondence between the bits of the two bitmaps and a bit should be set to '1' if the corresponding attribute bit is to be updated. Enumerations are provided (which can be logical-ORed):

Bits	Enumeration
0	CLD_IASZONE_STATUS_MASK_ALARM1
1	CLD_IASZONE_STATUS_MASK_ALARM2
2	CLD_IASZONE_STATUS_MASK_TAMPER
3	CLD_IASZONE_STATUS_MASK_BATTERY
4	CLD_IASZONE_STATUS_MASK_SUPERVISION_REPORTS
5	CLD_IASZONE_STATUS_MASK_RESTORE_REPORTS
6	CLD_IASZONE_STATUS_MASK_TROUBLE
7	CLD_IASZONE_STATUS_MASK_AC_MAINS
8	CLD_IASZONE_STATUS_MASK_TEST
9	CLD_IASZONE_STATUS_MASK_BATTERY_DEFECT
10-15	Reserved

- *bStatusState*: Boolean indicating the value to which the attribute bits to be updated must be set - enumerations are provided:
  - CLD_IASZONE_STATUS_MASK_SET (1)
  - CLD_IASZONE_STATUS_MASK_RESET (0)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Functions

eCLD_IASZoneUpdateZoneState

```
teZCL_Status eCLD_IASZoneUpdateZoneState(
    uint8 u8SourceEndPoint,
    teCLD_IASZoneState eZoneState);
```

Description This function can be used on an IAS Zone cluster server to update the zone state value stored in the e8ZoneState attribute, described in Section 37.2. This attribute indicates whether or not the server is enrolled with a client on a CIE device. The function checks that the specified state is valid.

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the IAS Zone cluster resides
- *eZoneState*: Zone state value to be written to the attribute, one of:
  - E_CLD_IASZONE_STATE_NOT_ENROLLED (0x00)
  - E_CLD_IASZONE_STATE_ENROLLED (0x01)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Functions

eCLD_IASZoneUpdateZoneType

```
teZCL_Status eCLD_IASZoneUpdateZoneType(
    uint8 u8SourceEndPoint,
    teCLD_IASZoneType eIASZoneType);
```

Description This function can be used on an IAS Zone cluster server to update the zone type value stored in the e16ZoneType attribute. The possible values are listed in Section 37.2 and the function checks that the specified type is one of these values.

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the IAS Zone cluster resides *eIAS-ZoneType*: Zone type value to be written to the attribute (for the possible values, refer to Section 37.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Functions

eCLD_IASZoneUpdateZoneID

```
teZCL_Status eCLD_IASZoneUpdateZoneID(
    uint8 u8SourceEndPoint,
    uint8 u8IASZoneId);
```

Description This function can be used on an IAS Zone cluster server to update the zone ID value stored in the u8ZoneId attribute. This is an 8-bit user-defined identifier.

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the IAS Zone cluster resides
- *u8IASZoneId*: Zone ID value to be written to the attribute

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Functions

eCLD_IASZoneUpdateCIEAddress

```
teZCL_Status eCLD_IASZoneUpdateCIEAddress(
    uint8 u8SourceEndPoint,
    u64IEEEAddress u64CIEAddress);
```

Description This function can be used on an IAS Zone cluster server to update the 64-bit IEEE/MAC address stored in the u64IASCIEAddress attribute. This is the address of the CIE device to which the local device should send commands and notifications.

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the IAS Zone cluster resides
- *u64CIEAddress*: IEEE/MAC address to be written to the attribute

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Functions

eCLD_IASZoneEnrollReqSend

```
teZCL_Status eCLD_IASZoneEnrollReqSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_IASZone_EnrollRequestPayload *psPayload);
```

Description This function can be used on an IAS Zone cluster server to send an IAS Zone Enroll Request to an IAS Zone client.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: : Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload*: Pointer to a structure containing the payload for the command (see Section 37.6.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_IASZoneEnrollRespSend

```
teZCL_Status eCLD_IASZoneEnrollRespSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_IASZone_EnrollResponsePayload *psPayload);
```

Description This function can be used on an IAS Zone cluster client to send an IAS Zone Enroll Response to the IAS Zone server.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId* Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress* Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber* Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload* Pointer to a structure containing the payload for the command (see Section 37.6.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_IASZoneStatusChangeNotificationSend

```
teZCL_Status eCLD_IASZoneStatusChangeNotificationSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
```

(continues on next page)

(continued from previous page)

```
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_IASZone_StatusChangeNotificationPayload
    *psPayload);
```

Description This function can be used on IAS Zone cluster server to send a Zone Status Change Notification to the IAS Zone client.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload*: Pointer to a structure containing the payload for the command (see Section 37.6.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_IASZoneNormalOperationModeReqSend

```
teZCL_Status eCLD_IASZoneNormalOperationModeReqSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used on IAS Zone cluster client to send a request the IAS Zone server to initiate normal operation mode. If required, this command must be enabled in the compile-time options, as described in Section 37.7.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_IASZoneTestModeReqSend

```
teZCL_Status eCLD_IASZoneTestModeReqSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_IASZone_InitiateTestModeRequestPayload
    *psPayload);
```

Description This function can be used on IAS Zone cluster client to send a request to the IAS Zone server to initiate test mode and operate in this mode for a specified time. If required, this command must be enabled in the compile-time options, as described in Section 37.7.

Test mode allows the target device to be temporarily isolated from the IAS to allow configuration/adjustment of the device. Alternatively, the whole IAS can be put into test mode for maintenance, but the command issued by this function only affects the individual target IAS Zone cluster server(s).

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload*: Pointer to a structure containing the payload for the command (see Section 37.6.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic:*IAS Zone Cluster*

Structures

Custom Data Structure The IAS Zone cluster requires extra storage space to be allocated to be used by internal functions. The structure definition for this storage is shown below:

```
typedef struct
{
    tsCLD_IASZone_InitiateTestModeRequestPayload sTestMode;
    tsZCL_ReceiveEventAddress      sReceiveEventAddress;
    tsZCL_CallBackEvent            sCustomCallBackEvent;
```

(continues on next page)

(continued from previous page)

```
    tsCLD_IASZoneCallBackMessage  sCallBackMessage;
} tsCLD_IASZone_CustomDataStructure;
```

The fields are for internal use and no knowledge of them is required.

Parent topic: Structures

Custom Command Payloads The following structures contain the payloads for the IAS Zone cluster custom commands.

'Enroll Request' Payload The following structure contains the payload of an Enroll Request command.

```
typedef struct
{
    zenum16     e16ZoneType;
    uint16      u16ManufacturerCode;
}tsCLD_IASZone_EnrollRequestPayload;
```

where:

- e16ZoneType is the zone type of the local (sending) node, as specified in the e``16ZoneType attribute (see Section 37.2)
- u16ManufacturerCode is the manufacturer ID code that is held in the Node Descriptor of the local (sending) node

'Enroll Response' Payload The following structure contains the payload of an Enroll Response command.

```
typedef struct
{
   teCLD_IASZoneZoneEnrollRspCode    e8EnrollResponseCode;
   uint8                             u8ZoneID;
}tsCLD_IASZone_EnrollResponsePayload;
```

where:

- e8EnrollResponseCode is a code indicating the outcome of the corresponding Enroll Request, one of:

Enumeration	Description
E_CLD_IASZONE_ENROLL_RESP_SUCCE	Requested enrollment successful
E_CLD_IASZONE_ENROLL_RESP_NOT_S	Zone type of requesting device is not known/supported by the CIE device
E_CLD_IASZONE_ENROLL_RESP_NO_EN	CIE device is not allowing new zones to be enrolled at the present time
E_CLD_IASZONE_ENROLL_RESP_TOO_M	CIE device has reached its limit for the number of zones that it can enroll

- u8ZoneID is the index of the entry for the enrollment which has been added to the Zone table on the CIE device (only valid for a successful enrollment)

'Zone Status Change Notification' Payload The following structure contains the payload of a Zone Status Change Notification command.

```
typedef struct
{
  zbmap16    b16ZoneStatus;
  zbmap8     b8ExtendedStatus;
  zuint8     u8ZoneId;
  zuint16    u16Delay;
}tsCLD_IASZone_StatusChangeNotificationPayload;
```

where:

- b16ZoneStatus contains the new/current status of the (sending) zone device, as indicated in the e``8ZoneState attribute - one of:
  - E_CLD_IASZONE_STATE_NOT_ENROLLED (0x01)
  - E_CLD_IASZONE_STATE_ENROLLED (0x02)
- b8ExtendedStatus can be optionally used to indicate further status information, but otherwise should be set to zero
- u8ZoneId is the index of the entry for the (sending) device in the Zone table on the CIE device
- u16Delay is is the time-delay, in quarter-seconds, between the status change taking place in the e``8ZoneState attribute and the successful transmission of the Zone Status Change Notification (this value can be used in assessing network traffic congestion)

'Initiate Test Mode Request' Payload The following structure contains the payload of an Initiate Test Mode Request command.

```
typedef struct
{
   uint8    u8TestModeDuration;
   uint8    u8CurrentZoneSensitivityLevel;
}tsCLD_IASZone_InitiateTestModeRequestPayload;
```

where:

- u8TestModeDuration is the duration, in seconds, for which the device should remain in test mode
- u8CurrentZoneSensitivityLevel is the current sensitivity level for the zone, as indicated in the u8CurrentZoneSensitivityLevel attribute (see Section 37.2)

Parent topic: Structures

Parent topic:*IAS Zone Cluster*

Compile-time options To enable the IAS Zone cluster in the code to be built, it is necessary to add the following to the **zcl_options.h** file:

```
#define CLD_IASZONE
```

In addition, to include the software for a cluster client or server or both, it is necessary to add one of the following to the same file:

```
#define IASZONE_SERVER
#define IASZONE_CLIENT
```

Optional Attributes Add this line to enable the optional Number Of Zone Sensitivity Levels attribute:

```
#define CLD_IASZONE_ATTR_ID_NUMBER_OF_ZONE_SENSITIVITY_LEVELS
```

Add this line to enable the optional Current Zone Sensitivity Level attribute:

```
#define CLD_IASZONE_ATTR_ID_CURRENT_ZONE_SENSITIVITY_LEVEL
```

Global Attributes Add this line to define the value (n) of the Cluster Revision attribute:

```
#define CLD_IASZONE_CLUSTER_REVISION <n>
```

The default value is 1, which corresponds to the revision of the cluster in the ZCL r6 specification (see Section 2.4).

Optional Commands Add this line to enable the optional Initiate Normal Operation Mode command:

```
#define CLD_IASZONE_CMD_INITIATE_NORMAL_OPERATION_MODE
```

Add this line to enable the optional Initiate Test Mode command:

```
#define CLD_IASZONE_CMD_INITIATE_TEST_MODE
```

Disable APS Acknowledgements for Bound Transmissions APS acknowledgements for bound transmissions from this cluster can be disabled by defining:

```
#define CLD_IASZONE_BOUND_TX_WITH_APS_ACK_DISABLED
```

Parent topic:*IAS Zone Cluster*

IAS Ancillary Control Equipment Cluster This chapter describes the IAS Ancillary Control Equipment (ACE) cluster, which provides a control interface to a CIE (Control and Indicating Equipment) device in an IAS (Intruder Alarm System).

The IAS ACE cluster has a Cluster ID of 0x0501.

Overview The IAS ACE cluster provides a control interface to a CIE (Control and Indicating Equipment) device in an IAS (Intruder Alarm System). For example, it allows a remote control unit to be used to configure the IAS via a CIE device. The server side of the cluster is implemented on the CIE device and the client side is implemented on the remote device.

To use the functionality of this cluster, you must include the file **IASACE.h** in your application and enable the cluster by defining CLD_IASACE in the **zcl_options.h** file.

The inclusion of the client or server software must be pre-defined in the application's compile-time options (in addition, if the cluster is to reside on a custom endpoint then the role of client or server must also be specified when creating the cluster instance).

The compile-time options for the IAS ACE cluster are fully detailed in Section 38.9.

Parent topic:*IAS Ancillary Control Equipment Cluster*

IAS ACE Structure and Attributes The structure definition for the IAS ACE cluster is shown below.

```
typedef struct
{
  zuint16     u16ClusterRevision;
}   tsCLD_IASACE;
```

where u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specification on which this cluster instance is based. The cluster specification in the ZCL r6 corresponds to a cluster revision of 1. The value is incremented by one for each subsequent revision of the cluster specification. This attribute is also described in Section 2.4.

Parent topic:*IAS Ancillary Control Equipment Cluster*

Table and Parameters The IAS ACE cluster server hosts the following table and sets of parameters:

- **Zone table:** The Zone table contains an entry for each enrolled zone. Each entry stores the identifier and type of the zone, as well as the IEEE/MAC address of the device which hosts the zone (see Section 38.7.2).
- **Zone parameters:** This set of parameters contains certain zone properties including the zone status, the zone name/label and the zone arm/disarm code (see Section 38.7.3)
- **Panel parameters:** This set of parameters contains certain status information about the display panel and alarm (see Section 38.7.4).

Parent topic:*IAS Ancillary Control Equipment Cluster*

Command Summary The IAS ACE cluster includes a number of commands that can be sent by the application on the client or server. These commands are summarised below.

- *Table 50* lists the commands that can be issued on the client.
- *Table 51* lists the commands that can be issued on the server.

Functions are provided to send these commands - these functions are indicated in the descriptions below and detailed in Section 38.6.

IAS ACE Cluster Commands from Client to Server

Command	Description and Function
Arm	Instructs the server to put all or certain enrolled zones into the 'armed' state or put all of them into the 'disarmed' state.eCLD_IASACE_ArmSend()
Bypass	Instructs the server to take one or more specified zones out of the system for the current activation (these zones are reinstated the next time the system is dis-armed and to exclude them again the next time the system is armed, the Bypass command must be re-sent before sending the Arm command).eCLD_IASACE_BypassSend()
Emergency	Instructs the server to put the alarm in the 'Emergency' state.eCLD_IASACE_EmergencySend()
Fire	Instructs the server to put the alarm in the 'Fire' state.eCLD_IASACE_FireSend()
Panic	Instructs the server to put the alarm in the 'Panic' state.eCLD_IASACE_PanicSend()
Get Zone ID Map	Requests the Zone IDs that have been allocated to zones.eCLD_IASACE_GetZoneIDMapSend()
Get Zone Information	Requests information on a specified zone.eCLD_IASACE_GetZoneInfoSend()
Get Panel Status	Requests the current status of the (display) panel.eCLD_IASACE_GetPanelStatusSend()
Get Bypassed Zone List	Requests a list of the currently bypassed zones. eCLD_IASACE_GetBypassedZoneListSend()
Get Zone Status	Requests a list of either all zones with their status or those zones with a particular status (that is, all zones with the b16ZoneStatus attribute of the IAS Zone cluster having a certain value). eCLD_IASACE_GetZoneStatusSend()

IAS ACE Cluster Commands from Server to Client

Command	Description and Function
Set Bypassed Zone List	Informs the client which zones are currently bypassed and can be sent in response to a Bypassed Zone List command, Get eCLD_IASACE_SetBypassedZoneListSend()
Zone Status Changed	Informs the client that the status (value of the b16ZoneStatus attribute of the IAS Zone cluster) of a particular zone has changed.eCLD_IASACE_ZoneStatusChangedSend()
Panel Status Changed	Informs the client that the status of the (display) panel has changed. eCLD_IASACE_PanelStatusChanged()

Parent topic:*IAS Ancillary Control Equipment Cluster*

IAS ACE Events The IAS ACE cluster has its own events that are handled through the callback mechanism outlined in *Chapter 3*. If a device uses the IAS ACE cluster then IAS ACE event handling must be included in the callback function for the associated endpoint, where this callback function is registered through the relevant endpoint registration function (for example, through

eHA_RegisterIASCIEEndPoint() for a CIE device). The relevant callback function will then be invoked when an IAS ACE event occurs.

For an IAS ACE event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsCLD_IASACECallBackMessage structure:

```
typedef struct
{
uint8    u8CommandId;
  union
  {
  tsCLD_IASACE_ArmPayload  *psArmPayload;
  tsCLD_IASACE_BypassPayload     *psBypassPayload;
  tsCLD_IASACE_GetZoneInfoPayload   *psGetZoneInfoPayload;
  tsCLD_IASACE_GetZoneStatusPayload   *psGetZoneStatusPayload;
  tsCLD_IASACE_ArmRespPayload      *psArmRespPayload;
  tsCLD_IASACE_GetZoneIDMapRespPayload   *psGetZoneIDMapRespPayload;
  tsCLD_IASACE_GetZoneInfoRespPayload   *psGetZoneInfoRespPayload;
  tsCLD_IASACE_ZoneStatusChangedPayload   *psZoneStatusChangedPayload;
  tsCLD_IASACE_PanelStatusChangedOrGetPanelStatusRespPayload
   *psPanelStatusChangedOrGetPanelStatusRespPayload;
  tsCLD_IASACE_SetBypassedZoneListPayload    *psSetBypassedZoneListPayload;
  tsCLD_IASACE_BypassRespPayload    *psBypassRespPayload;
  tsCLD_IASACE_GetZoneStatusRespPayload   *psGetZoneStatusRespPayload;
    } uMessage;
} tsCLD_IASACECallBackMessage;
```

When an IAS ACE event occurs, one of twelve command types could have been received. The relevant command type is specified through the u8CommandId field of the tsCLD_IASACECallBackMessage structure. The possible command/event types are detailed in *Table 52* below (for command descriptions, refer to Section 38.4).

In the case where an IAS Arm or Bypass command has been received and results in a change to a Zone parameter on the cluster server (e.g. an update of the zone status u8ZoneStatusFlag), a second event will be generated before any response is sent. This is a 'cluster update' event for which the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_UPDATE. This prompts the application to perform any required actions such as saving persistent data and refreshing a display.

u8CommandId Enumeration	Description
Server Events	
E_CLD_IASACE_CMD_ARM	An IAS ACE Arm command has been received by the server
E_CLD_IASACE_CMD_BYPASS	An IAS ACE Bypass command has been received by the server
E_CLD_IASACE_CMD_EMERGENCY	An IAS ACE Emergency command has been received by the server
E_CLD_IASACE_CMD_FIRE	An IAS ACE Fire command has been received by the server
E_CLD_IASACE_CMD_PANIC	An IAS ACE Panic command has been received by the server
E_CLD_IASACE_CMD_GET_ZONE_I	An IAS ACE Get Zone ID Map command has been received by the server
E_CLD_IASACE_CMD_GET_ZONE_I	An IAS ACE Get Zone Information command has been received by the server
E_CLD_IASACE_CMD_GET_PANEL_	An IAS ACE Get Panel Status command has been received by the server
E_CLD_IASACE_CMD_GET_BYPASS	An IAS ACE Get Bypassed Zone List command has been received by the server
E_CLD_IASACE_CMD_GET_ZONE_S	An IAS ACE Get Zone Status command has been received by the server
Client Events	
E_CLD_IASACE_CMD_ARM_RESP	An IAS ACE Arm Response command has been received by the client
E_CLD_IASACE_CMD_GET_ZONE_I	An IAS ACE Get Zone ID Map Response command has been received by the client
E_CLD_IASACE_CMD_GET_ZONE_I	An IAS ACE Get Zone Information Response command has been received by the client
E_CLD_IASACE_CMD_ZONE_STATU	An IAS ACE Zone Status Changed command has been received by the client
E_CLD_IASACE_CMD_PANEL_STAT	An IAS ACE Panel Status Changed command has been received by the client
E_CLD_IASACE_CMD_GET_PANEL_	An IAS ACE Get Panel Status Response command has been received by the client
E_CLD_IASACE_CMD_SET_BYPASSED_ZONE_LIST	An IAS ACE Set Bypassed Zone List command has been received by the client
E_CLD_IASACE_CMD_BYPASS_RES	An IAS ACE Bypass Response command has been received by the client
E_CLD_IASACE_CMD_GET_ZONE_S	An IAS ACE Get Zone Status Response command has been received by the client

Parent topic:*IAS Ancillary Control Equipment Cluster*

Functions The following IAS ACE cluster functions are provided in the NXP implementation of the ZCL:

1. eCLD_IASACECreateIASACE
2. eCLD_IASACEAddZoneEntry
3. eCLD_IASACERemoveZoneEntry
4. eCLD_IASACEGetZoneTableEntry
5. eCLD_IASACEGetEnrolledZones

6. eCLD_IASACESetPanelParameter
7. eCLD_IASACEGetPanelParameter
8. eCLD_IASACESetZoneParameter
9. eCLD_IASACESetZoneParameterValue
10. eCLD_IASACEGetZoneParameter
11. eCLD_IASACE_ArmSend
12. eCLD_IASACE_BypassSend
13. eCLD_IASACE_EmergencySend
14. eCLD_IASACE_FireSend
15. eCLD_IASACE_PanicSend
16. eCLD_IASACE_GetZoneIDMapSend
17. eCLD_IASACE_GetZoneInfoSend
18. eCLD_IASACE_GetPanelStatusSend
19. eCLD_IASACE_SetBypassedZoneListSend
20. eCLD_IASACE_GetBypassedZoneListSend
21. eCLD_IASACE_GetZoneStatusSend
22. eCLD_IASACE_ZoneStatusChangedSend
23. eCLD_IASACE_PanelStatusChanged

eCLD_IASACECreateIASACE

```
teZCL_Status eCLD_IASACECreateIASACE(
tsZCL_ClusterInstance *psClusterInstance,
bool_t bIsServer,
tsZCL_ClusterDefinition *psClusterDefinition,
void *pvEndPointSharedStructPtr,
tsCLD_IASACECustomDataStructure
*psCustomDataStructure);
```

Description This function creates an instance of the IAS ACE cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function will create an IAS ACE cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions.

Note: This function must not be called for an endpoint on which a standard ZigBee device is used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function.

When used, this function must be called after the stack has been started and after the ZCL has been initialized.

Parameters

- *psClusterInstance*: Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initializing individual structure fields.

- *bIsServer*: Type of cluster instance (server or client) to be created: *TRUE - server*, *FALSE - client*
- *psClusterDefinition*: Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the IAS ACE cluster.
- *pvEndPointSharedStructPtr*: Set this pointer to NULL for this cluster
- *psCustomDataStructure*: Pointer to a structure containing the storage for internal functions of the cluster (see Section 38.7.1)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_IASACEAddZoneEntry

```
teZCL_CommandStatus eCLD_IASACEAddZoneEntry(
    uint8 u8SourceEndPointId,
    uint16 u16ZoneType,
    uint64 u64IeeeAddress,
    uint8 *pu8ZoneID);
```

Description This function can be used on an IAS ACE cluster server to create an entry in the local Zone table - that is, to add the details of a zone to the table after receiving a Zone Enrollment Request (and before sending a Zone Enrollment Response).

The details of the zone are provided in the function parameters. The function checks that the supplied pointer to the Zone ID is not NULL and that the supplied IEEE address is valid. The function can then add the zone details to the Zone table, provided that there is a free entry in the table.

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the IAS ACE cluster resides
- *u16ZoneType*: Value indicating the type of zone to be added to the table (for the possible values, refer to the description of the attribute e``16ZoneType of the IAS Zone cluster in Section 37.2)
- *u64IeeeAddress*: IEEE address of the device which hosts the zone
- *pu8ZoneID*: Pointer to an identifier of the zone to be added to the table

Returns

- E_ZCL_CMDS_SUCCESS (zone successfully added to Zone table)
- E_ZCL_CMDS_FAILURE (cluster instance not found)
- E_ZCL_CMDS_INVALID_FIELD (pointer to Zone ID is NULL)
- E_ZCL_CMDS_INVALID_VALUE (IEEE address is invalid)

- E_ZCL_CMDS_INSUFFICIENT_SPACE (no free entry in Zone table)

Parent topic: Functions

eCLD_IASACERemoveZoneEntry

```
teZCL_CommandStatus eCLD_IASACERemoveZoneEntry(
  uint8 u8SourceEndPointId,
    uint8 u8ZoneID,
    uint64 *pu64IeeeAddress);
```

Description This function can be used on an IAS ACE cluster server to remove an existing entry from the local Zone table - that is, to delete the details of a zone in the table and release the table entry for re-use. Thus, this function can be used to unenroll a zone.

The zone to be removed is specified by means of the Zone ID. The function checks that the supplied pointer to a location to receive the IEEE address is not NULL. The function then searches for the relevant table entry using the supplied Zone ID and, if found, returns its IEEE address via the supplied location and frees the table entry by setting the IEEE address in the table entry to zero. The returned IEEE address can be used by a (local) CIE device application to send a request to the relevant Zone device to set its IAS Zone cluster attribute u64IASCIEAddress to all zeros (writing to remote attributes is described in Section 2.3.3.1).

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the IAS ACE cluster resides
- *u8ZoneID*: Zone ID of zone to be removed from table
- *pu64IeeeAddress*: Pointer to location to receive the IEEE address found in the table entry to be removed

Returns

- E_ZCL_CMDS_SUCCESS (zone successfully removed from Zone table)
- E_ZCL_CMDS_FAILURE (cluster instance not found)
- E_ZCL_CMDS_INVALID_FIELD (pointer to IEEE address location is NULL)
- E_ZCL_CMDS_NOT_FOUND (entry with specified Zone ID not found in table)

Parent topic: Functions

eCLD_IASACEGetZoneTableEntry

```
teZCL_CommandStatus eCLD_IASACEGetZoneTableEntry(
    uint8 u8SourceEndPointId,
    uint8 u8ZoneID,
    tsCLD_IASACE_ZoneTable **ppsZoneTable);
```

Description This function can be used on an IAS ACE cluster server to obtain the details of a specified zone from the local Zone table.

The zone of interest is specified by means of its Zone ID. The function searches for the relevant table entry using the supplied Zone ID and, if found, returns the zone information from the table entry via the supplied structure (see Section 38.7.2).

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the IAS ACE cluster resides
- *u8ZoneID*: Zone ID of zone for which details required from table
- *ppsZoneTable*: Pointer to a pointer to a structure to receive obtained zone information (see Section 38.7.2)

Returns

- E_ZCL_CMDS_SUCCESS (zone details successfully obtained from Zone table)
- E_ZCL_CMDS_FAILURE (cluster instance not found)
- E_ZCL_CMDS_NOT_FOUND (entry with specified Zone ID not found in table)

Parent topic: Functions

eCLD_IASACEGetEnrolledZones

```
teZCL_CommandStatus eCLD_IASACEGetEnrolledZones(
    uint8 u8SourceEndPointId,
    uint8 *pu8ZoneID,
    uint8 *pu8NumOfEnrolledZones);
```

Description This function can be used on an IAS ACE cluster server to obtain a list of the enrolled zones from the local Zone table.

The function searches the Zone table and returns a list of the Zone IDs of all the enrolled zones (for which there are table entries). The number of enrolled zones is also returned.

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the IAS ACE cluster resides
- *pu8ZoneID*: Pointer to a location to receive the first Zone ID in the reported list of enrolled zones
- *pu8NumOfEnrolledZones*: Pointer to a location to receive the number of enrolled zones reported in the above list

Returns

- E_ZCL_CMDS_SUCCESS (zone list successfully obtained from Zone table)
- E_ZCL_CMDS_FAILURE (cluster instance not found)
- E_ZCL_CMDS_INVALID_FIELD (a supplied pointer is NULL)

Parent topic: Functions

eCLD_IASACESetPanelParameter

```
teZCL_Status eCLD_IASACESetPanelParameter(
    uint8 u8SourceEndPointId,
    teCLD_IASACE_PanelParameterID eParameterId,
    uint8 u8ParameterValue);
```

Description This function can be used on an IAS ACE cluster server to set the value of a Panel parameter. The Panel parameters are held on the server in a tsCLD_IASACE_PanelParameter structure (see Section 38.7.4) and this function can be used to write a value to one parameter in the structure. The function verifies that the specified parameter identifier is valid before attempting the write.

If this function is used to set the Panel parameter ePanelStatus, an IAS ACE Panel Status Changed command is automatically sent to all bound clients.

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the IAS ACE cluster resides
- *eParameterId*: Enumeration identifying the Panel parameter to be set, one of:
  - E_CLD_IASACE_PANEL_PARAMETER_PANEL_STATUS
  - E_CLD_IASACE_PANEL_PARAMETER_SECONDS_REMAINING
  - E_CLD_IASACE_PANEL_PARAMETER_AUDIBLE_NOTIFICATION
  - E_CLD_IASACE_PANEL_PARAMETER_ALARM_STATUS
- *u8ParameterValue*: Value to be written to the parameter

Returns

- E_ZCL_SUCCESS (Panel parameter successfully set)
- E_ZCL_ERR_CLUSTER_NOT_FOUND (cluster instance not found)
- E_ZCL_ERR_ATTRIBUTE_NOT_FOUND (Panel parameter identifier invalid)

Parent topic: Functions

eCLD_IASACEGetPanelParameter

```
teZCL_Status eCLD_IASACEGetPanelParameter(
    uint8 u8SourceEndPointId,
    teCLD_IASACE_PanelParameterID eParameterId,
    uint8 *pu8ParameterValue);
```

Description This function can be used on an IAS ACE cluster server to obtain the value of a Panel parameter. The Panel parameters are held on the server in a tsCLD_IASACE_PanelParameter structure (see Section 38.7.4) and this function can be used to read the value of one parameter in the structure. The function verifies that the specified parameter identifier is valid before attempting the read.

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the IAS ACE cluster resides
- *eParameterId* : Enumeration identifying the Panel parameter to be read, one of:
- E_CLD_IASACE_PANEL_PARAMETER_PANEL_STATUS
- E_CLD_IASACE_PANEL_PARAMETER_SECONDS_REMAINING
- E_CLD_IASACE_PANEL_PARAMETER_AUDIBLE_NOTIFICATION
- E_CLD_IASACE_PANEL_PARAMETER_ALARM_STATUS
- *pu8ParameterValue*: Pointer to location to receive read parameter value

Returns

- E_ZCL_SUCCESS (Panel parameter successfully read)
- E_ZCL_ERR_CLUSTER_NOT_FOUND (cluster instance not found)
- E_ZCL_ERR_PARAMETER_NULL (specfied pointer is NULL)
- E_ZCL_ERR_ATTRIBUTE_NOT_FOUND (Panel parameter identifier invalid)

Parent topic: Functions

eCLD_IASACESetZoneParameter

```
teZCL_Status eCLD_IASACESetZoneParameter(
    uint8 u8SourceEndPointId,
    teCLD_IASACE_ZoneParameterID eParameterId,
    uint8 u8ZoneID,
    uint8 u8ParameterLength,
    uint8 *pu8ParameterValue);
```

Description This function can be used on an IAS ACE cluster server to set the value of a Zone parameter. The Zone parameters for a particular Zone ID are held on the server in a tsCLD_IASACE_ZoneParameter structure (see Section 38.7.3) and this function can be used to write a value to one parameter in the structure. The specified zone must have been enrolled in the local Zone table. Before attempting the write, the function verifies that the specified Zone ID is present in the Zone table and that the specified parameter identifier is valid.

If this function is used to set the Zone parameter eZoneStatus, an IAS ACE Zone Status Changed command is automatically sent to all bound clients.

The function requires the parameter value to be provided as a **uint8** array. This is to allow one of the array parameters, au8ZoneLabel[] or au8ArmDisarmCode[], to be set - the corresponding string parameter, sZoneLabel or sArmDisarmCode, will be set automatically. The function **eCLD_IASACESetZoneParameterValue()** provides an easier way of setting one of the non-array/non-string parameters.

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the IAS ACE cluster resides
- *eParameterId* : Enumeration identifying the Zone parameter to be set, one of:
- : E_CLD_IASACE_ZONE_PARAMETER_ZONE_CONFIG_FLAG
- E_CLD_IASACE_ZONE_PARAMETER_ZONE_STATUS_FLAG
- E_CLD_IASACE_ZONE_PARAMETER_ZONE_STATUS
- E_CLD_IASACE_ZONE_PARAMETER_AUDIBLE_NOTIFICATION
- E_CLD_IASACE_ZONE_PARAMETER_ZONE_LABEL
- E_CLD_IASACE_ZONE_PARAMETER_ARM_DISARM_CODE
- *u8ZoneID*: Zone ID of zone information to be updated
- *u8ParameterLength*: Number of *uint8* elements in the array containing the parameter value to be set
- *pu8ParameterValue*: Pointer to a location containing the first element of the array containing the parameter value to be set

Returns

- E_ZCL_SUCCESS (Zone parameter successfully set)
- E_ZCL_ERR_CLUSTER_NOT_FOUND (cluster instance not found)
- E_ZCL_ERR_ATTRIBUTE_NOT_FOUND (Zone parameter identifier invalid)
- E_ZCL_ERR_NO_REPORT_ENTRIES (Zone ID not found in Zone table)
- E_ZCL_ERR_PARAMETER_NULL (Pointer to location containing value is NULL)
- E_ZCL_ERR_PARAMETER_RANGE (specified array length too long to be stored)

Parent topic: Functions

eCLD_IASACESetZoneParameterValue

```
teZCL_Status eCLD_IASACESetZoneParameterValue(
    uint8 u8SourceEndPointId,
    teCLD_IASACE_ZoneParameterID eParameterId,
    uint8 u8ZoneID,
    uint16 u16ParameterValue);
```

Description This function can be used on an IAS ACE cluster server to set the value of a Zone parameter. The Zone parameters for a particular Zone ID are held on the server in a tsCLD_IASACE_ZoneParameter structure (see Section 38.7.3) and this function can be used to write a value to one of the non-string/non-array parameters in the structure. The specified zone must have been enrolled in the local Zone table. Before attempting the write, the function verifies that the specified Zone ID is present in the Zone table and that the specified parameter identifier is valid.

If this function is used to set the Zone parameter eZoneStatus, an IAS ACE Zone Status Changed command is automatically sent to all bound clients.

This function cannot be used to set the string parameters sZoneLabel and sArmDisarmCode or the array parameters au8ZoneLabel[] and au8ArmDisarmCode[]. The function **eCLD_IASACESetZoneParameter()** must be used to set the string and array parameters.

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the IAS ACE cluster resides
- *eParameterId* : Enumeration identifying the Zone parameter to be set, one of:
  - E_CLD_IASACE_ZONE_PARAMETER_ZONE_CONFIG_FLAG
  - E_CLD_IASACE_ZONE_PARAMETER_ZONE_STATUS_FLAG
  - E_CLD_IASACE_ZONE_PARAMETER_ZONE_STATUS
  - E_CLD_IASACE_ZONE_PARAMETER_AUDIBLE_NOTIFICATION
- *u8ZoneID*: Zone ID of zone information to be updated
- *u16ParameterValue*: Value to be written to the parameter

Returns

- E_ZCL_SUCCESS (Zone parameter successfully set)
- E_ZCL_ERR_CLUSTER_NOT_FOUND (cluster instance not found)
- E_ZCL_ERR_ATTRIBUTE_NOT_FOUND (Zone parameter identifier invalid)

- E_ZCL_ERR_NO_REPORT_ENTRIES (Zone ID not found in Zone table)

Parent topic: Functions

eCLD_IASACEGetZoneParameter

```
teZCL_Status eCLD_IASACEGetZoneParameter(
    uint8 u8SourceEndPointId,
    teCLD_IASACE_ZoneParameterID eParameterId,
    uint8 u8ZoneID,
    uint8 *pu8ParameterLength,
    uint8 *pu8ParameterValue);
```

Description This function can be used on an IAS ACE cluster server to obtain the value of a Zone parameter. The Zone parameters for a particular Zone ID are held on the server in a tsCLD_IASACE_ZoneParameter structure (see Section 38.7.3) and this function can be used to read the value of one parameter in the structure. Before attempting the read, the function verifies that the specified Zone ID is present in the Zone table and that the specified parameter identifier is valid.

The function expects the read parameter value to be returned as a **uint8** array.

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the IAS ACE cluster resides
- *eParameterId*: Enumeration identifying the Zone parameter to be read, one of:
  - E_CLD_IASACE_ZONE_PARAMETER_ZONE_CONFIG_FLAG
  - E_CLD_IASACE_ZONE_PARAMETER_ZONE_STATUS_FLAG
  - E_CLD_IASACE_ZONE_PARAMETER_ZONE_STATUS
  - E_CLD_IASACE_ZONE_PARAMETER_AUDIBLE_NOTIFICATION
  - E_CLD_IASACE_ZONE_PARAMETER_ZONE_LABEL
  - E_CLD_IASACE_ZONE_PARAMETER_ARM_DISARM_CODE
- *u8ZoneID*: Zone ID of zone information to be accessed
- **pu8ParameterLength*: Pointer to location to receive the number of *uint8* elements in the array containing the parameter value obtained
- **pu8ParameterValue*: Pointer to location to receive the first element of the array containing the parameter value obtained

Returns

- E_ZCL_SUCCESS (Zone parameter successfully read)
- E_ZCL_ERR_CLUSTER_NOT_FOUND (cluster instance not found)
- E_ZCL_ERR_PARAMETER_NULL (a specified pointer is NULL)
- E_ZCL_ERR_NO_REPORT_ENTRIES (Zone ID not found in Zone table)
- E_ZCL_ERR_ATTRIBUTE_NOT_FOUND (Zone parameter identifier invalid)
- E_ZCL_ERR_PARAMETER_RANGE (returned array too long to be stored)

Parent topic: Functions

eCLD_IASACE_ArmSend

```
teZCL_Status eCLD_IASACE_ArmSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_IASACE_ArmPayload *psPayload);
```

Description This function can be used on an IAS ACE cluster client to send an IAS ACE Arm command to an IAS ACE server. This command instructs the server to put all or certain enrolled zones into the 'armed' state or put all of them into the 'disarmed' state, according to the command payload (see Section 38.7.5).

The outcome of the request will be returned by the server in a response which will generate an E_CLD_IASACE_CMD_ARM_RESP event when received on the client.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload*: Pointer to a structure containing the payload for the command (see Section 38.7.5)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_IASACE_BypassSend

```
teZCL_Status eCLD_IASACE_BypassSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_IASACE_BypassPayload *psPayload);
```

Description This function can be used on an IAS ACE cluster client to send an IAS ACE Bypass command to an IAS ACE server. This command instructs the server to take one or more specified zones out of the system for the current activation.

Note: The bypassed zones will be reinstated the next time the system is disarmed. To exclude them again the next time the system is armed, the Bypass command must be re-sent before sending the Arm command.

The outcome of the request will be returned by the server in a response which will generate an E_CLD_IASACE_CMD_BYPASS_RESP event when received on the client.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload*: Pointer to a structure containing the payload for the command (see Section 38.7.5)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_IASACE_EmergencySend

    uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used on an IAS ACE cluster client to send an IAS ACE Emergency command to an IAS ACE server. This command instructs the server to put the alarm in the 'Emergency' state.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

    uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used on an IAS ACE cluster client to send an IAS ACE Fire command to an IAS ACE server. This command instructs the server to put the alarm in the 'Fire' state.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_IASACE_PanicSend

```
teZCL_Status eCLD_IASACE_PanicSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used on an IAS ACE cluster client to send an IAS ACE Panic command to an IAS ACE server. This command instructs the server to put the alarm in the 'Panic' state.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_IASACE_GetZoneIDMapSend

```
teZCL_Status eCLD_IASACE_GetZoneIDMapSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used on an IAS ACE cluster client to send an IAS ACE Get Zone ID Map command to an IAS ACE server. This command requests the Zone IDs that have been allocated to zones.

The requested information is returned by the server in a response which generates an E_CLD_IASACE_CMD_GET_ZONE_ID_MAP_RESP event when received on the client.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values

- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_IASACE_GetZoneInfoSend

```
teZCL_Status eCLD_IASACE_GetZoneInfoSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_IASACE_GetZoneInfoPayload *psPayload);
```

Description This function can be used on an IAS ACE cluster client to send an IAS ACE Get Zone Information command to an IAS ACE server. This command requests information on the zone specified in the command payload.

The requested information will be returned by the server in a response which will generate an E_CLD_IASACE_CMD_GET_ZONE_INFO_RESP event when received on the client.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP

- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload*: Pointer to a structure containing the payload for the command (see Section 38.7.5)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_IASACE_GetPanelStatusSend

```
teZCL_Status eCLD_IASACE_GetPanelStatusSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used on an IAS ACE cluster client to send an IAS ACE Get Panel Status command to an IAS ACE server. This command requests the current status of the (display) panel.

The requested information will be returned by the server in a response which will generate an E_CLD_IASACE_CMD_GET_PANEL_STATUS_RESP event when received on the client.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent

- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_IASACE_SetBypassedZoneListSend

```
teZCL_Status eCLD_IASACE_SetBypassedZoneListSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_IASACE_SetBypassedZonelistPayload *psPayload);
```

Description This function can be used on an IAS ACE cluster server to send an IAS ACE Set Bypassed Zone List command to an IAS ACE client. This command informs the client which zones are currently bypassed - the zones are specified in the command payload.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload*: Pointer to a structure containing the payload for the command (see Section 38.7.5)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_IASACE_GetBypassedZoneListSend

```
teZCL_Status eCLD_IASACE_GetBypassedZoneListSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used on an IAS ACE cluster client to send an IAS ACE Get Bypassed Zone List command to an IAS ACE server. This command requests a list of the currently bypassed zones.

The requested information will be returned by the server in a response which will generate an E_CLD_IASACE_CMD_SET_BYPASSED_ZONE_LIST event when received on the client.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL

- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_IASACE_GetZoneStatusSend

```
teZCL_Status eCLD_IASACE_GetZoneStatusSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_IASACE_GetZoneStatusPayload *psPayload);
```

Description This function can be used on an IAS ACE cluster client to send an IAS ACE Get Zone Status command to an IAS ACE server. This command requests either of the following:

- a list of all enrolled zones with their status
- a list of those zones with a particular status (that is, all zones with the b16ZoneStatus attribute of the IAS Zone cluster having a certain value)

The list required is specified in the bZoneStatusMaskFlag field of the command payload (see Section 38.7.5). If the second of the above lists is required, the status to look for is also specified in the payload.

The requested information is returned by the server in a response which generates an E_CLD_IASACE_CMD_GET_ZONE_STATUS_RESP event when received on the client. A single response may not be able to carry all the zone status information to be returned and more than one request (and associated response) would be needed. For this reason, the request allows a starting zone and the number of zones to be included in the response to be specified (in the request payload).

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request

- *psPayload*: Pointer to a structure containing the payload for the command (see Section 38.7.5)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_IASACE_ZoneStatusChangedSend

```
teZCL_Status eCLD_IASACE_ZoneStatusChangedSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_IASACE_ZoneStatusChangedPayload *psPayload);
```

Description This function can be used on an IAS ACE cluster server to send an IAS ACE Zone Status Changed command to an IAS ACE client. This command informs the client that the status of the specified zone has changed - that is, the value of the b16ZoneStatus attribute of the IAS Zone cluster for the zone has changed.

Note: This command is sent automatically when the function **eCLD_IASACESetZoneParameter()** is called on the server to update the u16ZoneStatus attribute for all the bound clients.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request

- *psPayload*: Pointer to a structure containing the payload for the command (see Section 38.7.5)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_IASACE_PanelStatusChanged

```
teZCL_Status eCLD_IASACE_PanelStatusChanged(
        uint8 u8SourceEndPointId,
        uint8 u8DestinationEndPointId,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        teCLD_IASACE_ServerCmdId eCommandId,
        tsCLD_IASACE_PanelStatusChangedOrGetPanelStatusRespPayload
        *psPayload);
```

Description This function can be used on an IAS ACE cluster server to send an IAS ACE Panel Status Changed command to an IAS ACE client. This command informs the client that the value of the panel parameter ePanelStatus (see Section 38.7.4) on the (local) CIE device has changed.

Note:

1. The IAS ACE Panel Status Changed command is sent automatically when the function **eCLD_IASACESetPanelParameter()** is called to update the ePanelStatus parameter.
2. The function alternatively provides the option of sending an IAS ACE Get Panel Status Response but, in practice, this response is sent automatically when a Get Panel Status Request is received.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP

- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *eCommandId*: Identifier of command to be sent - for Panel Status Changed command, always set to:: E_CLD_IASACE_CMD_PANEL_STATUS_CHANGED
- *psPayload*: Pointer to a structure containing the payload for the command (see Section 38.7.5)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Structures

Custom Data Structure The IAS ACE cluster requires extra storage space to be allocated to be used by internal functions. The structure definition for this storage is shown below:

```
typedef struct
{
    tsZCL_ReceiveEventAddress        sReceiveEventAddress;
    tsZCL_CallBackEvent              sCustomCallBackEvent;
    tsCLD_IASACECallBackMessage      sCallBackMessage;
#if (defined CLD_IASACE) && (defined IASACE_SERVER)
    tsCLD_IASACE_PanelParameter
                                sCLD_IASACE_PanelParameter;
    tsCLD_IASACE_ZoneParameter
          asCLD_IASACE_ZoneParameter[CLD_IASACE_ZONE_TABLE_SIZE];
    tsCLD_IASACE_ZoneTable
          asCLD_IASACE_ZoneTable[CLD_IASACE_ZONE_TABLE_SIZE];
#endif
} tsCLD_IASACECustomDataStructure;
```

The fields are for internal use and no knowledge of them is required.

Parent topic: Structures

Zone Table Entry The following structure contains a Zone table entry, used to hold the enrollment details of a zone.

```
typedef struct
{
    zuint8              u8ZoneID;
    zbmap16               u16ZoneType;
    zieeeaddress        u64IeeeAddress;
} tsCLD_IASACE_ZoneTable;
```

where:

- u8ZoneID is the identifier of the zone
- u16ZoneType is a value indicating the type of zone (for the possible values, refer to the description of the attribute e``16ZoneType of the IAS Zone cluster in Section 37.2)
- u64IeeeAddress is the IEEE/MAC address of the device which hosts the zone

Parent topic: Structures

Zone Parameters The following structure is used to store the 'zone parameters' on the IAS ACE cluster server.

```
typedef struct
{
    zbmap8                      u8ZoneConfigFlag;
    zbmap8                      u8ZoneStatusFlag;
    zbmap16                     eZoneStatus;
    zenum8                      eAudibleNotification;
    tsZCL_CharacterString           sZoneLabel;
    uint8
          au8ZoneLabel[CLD_IASACE_MAX_LENGTH_ZONE_LABEL];
    tsZCL_CharacterString           sArmDisarmCode;
    uint8
          au8ArmDisarmCode[CLD_IASACE_MAX_LENGTH_ARM_DISARM_CODE];
}tsCLD_IASACE_ZoneParameter;
```

where:

- u8ZoneConfigFlag is is a bitmap used to configure the temporal role of a zone (as Day, Night or Day/Night) and whether the zone is allowed to be bypassed. Macros are provided as follows:

Bit	Macro
0	CLD_IASACE_ZONE_CONFIG_FLAG_BYPASS *
1	CLD_IASACE_ZONE_CONFIG_FLAG_DAY_HOME
2	CLD_IASACE_ZONE_CONFIG_FLAG_NIGHT_SLEEP
3	CLD_IASACE_ZONE_CONFIG_FLAG_NOT_BYPASSED **
4-7	Reserved

- * Determines whether the zone is allowed to be bypassed: 1 - allowed, 0 - not allowed
- ** Used to configure a status of ZONE_NOT_BYPASSED in responses to Bypass commands
- u8ZoneStatusFlag is a bitmap used to indicate the current status of a zone as armed or bypassed. Macros are provided as follows:

Bit	Macro
0	CLD_IASACE_ZONE_STATUS_FLAG_BYPASS
1	CLD_IASACE_ZONE_STATUS_FLAG_ARM
2-7	Reserved

- e``ZoneStatus is the zone status as the value of the b16ZoneStatus attribute of the IAS Zone cluster (see Section 37.2)
- eAudibleNotification is a value specifying whether an audible notification (e.g. a chime) is required to signal a zone status change (enumerations are available in teCLD_IASACE_AudibleNotification - see Section 38.8.4):

Value	Status
0x00	Audible notification muted
0x01	Audible notification sounded
0x02 - 0xFF	Reserved

- sZoneLabel is the name/label for the zone represented as a character string
- au8ZoneLabel[] is the name/label for the zone represented as an array of ASCII values
- sArmDisarmCode is the arm/disarm code for the zone represented as a character string
- au8ArmDisarmCode[] is the arm/disarm code for the zone represented as an array of ASCII values

Parent topic: Structures

Panel Parameters The following structure is used to store the 'panel parameters' on the IAS ACE cluster server.

```
typedef struct
{
   zenum8    ePanelStatus;
   zuint8    u8SecondsRemaining;
   zenum8    eAudibleNotification;
   zenum8    eAlarmStatus;
}tsCLD_IASACE_PanelParameter;
```

where:

- ePanelStatus is a value indicating the status to be displayed on the panel, as follows (enumerations are available in teCLD_IASACE_PanelStatus - see Section 38.8.2):

Value	Status
0x00	Disarmed (all zones) and ready to be armed
0x01	Armed stay
0x02	Armed night
0x03	Armed away
0x04	Exit delay
0x05	Entry delay
0x06	Not ready to be armed
0x07	In alarm
0x08	Arming stay
0x09	Arming night
0x0A	Arming away
0x0B - 0xFF	Reserved

- u8SecondsRemaining represents the time, in seconds, that the server will remain in the displayed state when the latter is 'Exit delay' or 'Entry delay' (for other states, this field should be set to 0x00).
- eAudibleNotification is a value specifying whether an audible notification (e.g. a chime) is required to signal a zone status change (enumerations are available in teCLD_IASACE_AudibleNotification - see Section 38.8.4):

Value	Status
0x00	Audible notification muted
0x01	Audible notification sounded
0x02 - 0xFF	Reserved

- eAlarmStatus is a value indicating the alarm status/type when the panel's state is 'In Alarm', as follows (enumerations are available in teCLD_IASACE_AlarmStatus - see Section 38.8.3):

Value	Status
0x00	No alarm
0x01	Burglar
0x02	Fire
0x03	Emergency
0x04	Police panic
0x05	Fire panic
0x06	Emergency panic
0x07 - 0xFF	Reserved

Parent topic: Structures

Custom Command Payloads The following structures contain the payloads for the IAS ACE cluster custom commands.

'Arm' Command Payload The following structure contains the payload of a Arm command.

```
typedef struct
{
   zenum8                  eArmMode;
   tsZCL_CharacterString   sArmDisarmCode;
   zuint8                  u8ZoneID;
} tsCLD_IASACE_ArmPayload;
```

where:

- eArmMode is a value indicating the state of armament in which to put the zone (enumerations are available in teCLD_IASACE_ArmMode - see Section38.8.1):

Value	Status
0x00	Disarm
0x01	Arm day/home zones only
0x02	Arm night/sleep zones only
0x03	Arm all zones
0x04 - 0xFF	Reserved

- sArmDisarmCode is an 8-character string containing the arm/disarm code (if a code is not required, set to "00000000")

- u8ZoneID is the identifier of the zone to arm/disarm

'Bypass' Command Payload The following structure contains the payload of a Bypass command.

```
typedef struct
{
   zuint8                  u8NumOfZones;
   zuint8                 *pu8ZoneID;
   tsZCL_CharacterString   sArmDisarmCode;
} tsCLD_IASACE_BypassPayload;
```

where:

- u8NumOfZones is the number of zones to be 'bypassed' (taken out of the system)
- pu8ZoneID is a pointer to a list of identifiers specifying the zones to be bypassed (the number of zones in the list is specified in u8NumOfZones)
- sArmDisarmCode is an 8-character string containing the arm/disarm code (if a code is not required, set to "00000000")

'Get Zone Information' Command Payload The following structure contains the payload of a Get Zone Information command.

```
typedef struct
{
   zuint8          u8ZoneID;
} tsCLD_IASACE_GetZoneInfoPayload;
```

where u8ZoneID is the identifier of the zone on which information is required.

'Set Bypassed Zone List' Command Payload The following structure contains the payload of a Set Bypassed Zone List command.

```
typedef struct
{
   zuint8          u8NumofZones;
   zuint8         *pu8ZoneID;
} tsCLD_IASACE_SetBypassedZoneListPayload;
```

where:

- u8NumofZones is the number of zones in the new bypassed zone list
- pu8ZoneID is a pointer to the new bypassed zone list (the number of zones in the list is specified in u8NumOfZones)

'Get Zone Status' Command Payload The following structure contains the payload of a Get Zone Status command.

```
typedef struct
{
   zuint8          u8StartingZoneID;
   zuint8          u8MaxNumOfZoneID;
   zbool           bZoneStatusMaskFlag;
```

(continues on next page)

(continued from previous page)

```
    zbmap16         u16ZoneStatusMask;
} tsCLD_IASACE_GetZoneStatusPayload;
```

where:

- u8StartingZoneID is the identifier of the first zone for which status information is required
- u8MaxNumOfZoneID is the maximum number of zones for which status information should be returned
- bZoneStatusMaskFlag is a Boolean indicating whether status information should be returned for all zones or only for those zones with particular status values (specified through u16ZoneStatusMask below):
  - TRUE - only zones with specific status values
  - FALSE - all zones
- u16ZoneStatusMask is a 16-bit bitmap indicating the zone status values of interest (used when bZoneStatusMaskFlag is set to TRUE) - the response to the request will contain information only for those zones with a status value indicated in this bitmap:

Bit	Description
0	Alarm1:

1 - Opened or alarmed

0 - Closed or not alarned

| |1|Alarm2:

1 - Opened or alarmed

0 - Closed or not alarned

| |2|Tamper:

1 - Tampered with

0 - Not tampered with

| |3|Battery:

1 - Low

0 - OK

| |4|Supervision reports:

1 - Reports

0 - No reports

| |5|Restore reports:

1 - Reports

0 - No reports

| |6|Trouble:

1 - Trouble/failure

0 - OK

| |7|AC (mains):

1 - Fault

0 - OK

| |8|Test mode:

1 - Sensor in test mode

0 - Sensor in operational mode

| |9|Battery defect:

1 - Defective battery detected

0 - Battery OK

| |10-15|Reserved|

'Panel Status Changed or Get Panel Status Response' The following structure contains the payload of a Panel Status Changed command or Get Panel Status Response.

```
typedef struct
{
    zenum8        ePanelStatus;
    zuint8        u8SecondsRemaining;
    zenum8        eAudibleNotification;
    zenum8        eAlarmStatus;
} tsCLD_IASACE_PanelStatusChangedOrGetPanelStatusRespPayload;
```

where:

- ePanelStatus is a value indicating the status to be displayed on the panel, as follows (enumerations are available in teCLD_IASACE_PanelStatus - see Section 38.8.2):

Value	Status
0x00	Disarmed (all zones) and ready to be armed
0x01	Armed stay
0x02	Armed night
0x03	Armed away
0x04	Exit delay
0x05	Entry delay
0x06	Not ready to be armed
0x07	In alarm
0x08	Arming stay
0x09	Arming night
0x0A	Arming away
0x0B - 0xFF	Reserved

- u8SecondsRemaining represents the time, in seconds, that the server will remain in the displayed state when the latter is 'Exit delay' or 'Entry delay' (for other states, this field should be set to 0x00).
- eAudibleNotification is a value specifying whether an audible notification (e.g. a chime) is required to signal a zone status change (enumerations are available in teCLD_IASACE_AudibleNotification - see Section 38.8.4):

Value	Status
0x00	Audible notification muted
0x01	Audible notification sounded
0x02 - 0xFF	Reserved

- eAlarmStatus is a value indicating the alarm status/type when the panel's state is 'In Alarm', as follows (enumerations are available in teCLD_IASACE_AlarmStatus - see Section 38.8.3):

Value	Status
0x00	No alarm
0x01	Burglar
0x02	Fire
0x03	Emergency
0x04	Police panic
0x05	Fire panic
0x06	Emergency panic
0x07 - 0xFF	Reserved

Parent topic: Structures

Event Data Structures The following structures hold the data contained in certain IAS ACE cluster events.

E_CLD_IASACE_CMD_ARM_RESP Data

```
typedef struct
{
    zenum8          eArmNotification;
} tsCLD_IASACE_ArmRespPayload;
```

where eArmNotification is an enumeration indicating the outcome of the Arm command, one of:

- E_CLD_IASACE_ARM_NOTIF_ALL_ZONES_DISARMED
- E_CLD_IASACE_ARM_NOTIF_ONLY_DAY_HOME_ZONES_ARMED
- E_CLD_IASACE_ARM_NOTIF_ONLY_NIGHT_SLEEP_ZONES_ARMED
- E_CLD_IASACE_ARM_NOTIF_ALL_ZONES_ARMED
- E_CLD_IASACE_ARM_NOTIF_INVALID_ARM_DISARM_CODE
- E_CLD_IASACE_ARM_NOTIF_NOT_READY_TO_ARM
- E_CLD_IASACE_ARM_NOTIF_ALREADY_DISARMED

E_CLD_IASACE_CMD_GET_ZONE_ID_MAP_RESP Data

```
typedef struct
{
    zbmap16  au16ZoneIDMap[CLD_IASACE_MAX_BYTES_FOR_NUM_OF_ZONES];
} tsCLD_IASACE_GetZoneIDMapRespPayload;
```

where au16ZoneIDMap[``] is an array, each element being a 16-bit bitmap indicating whether each of a set of zone identifiers is allocated - a Zone ID is represented by a single bit which is set to '1' if the identifier value has been allocated and '0' otherwise.

Array Element	Bit	Zone ID
au16ZoneIDMap[0]	01: 15	0x000x01: 0x0F
au16ZoneIDMap[1]	01: 15	0x100x11: 0x1F
:	:	:
au16ZoneIDMap[N]	01:n:15	16N16N + 0x1:16N + 0xn:16N + 0xF

E_CLD_IASACE_CMD_GET_ZONE_INFO_RESP Data

```
typedef struct
{
    zuint8                  u8ZoneID;
    zbmap16                   u16ZoneType;
    zieeeaddress            u64IeeeAddress;
    tsZCL_CharacterString     sZoneLabel;
} tsCLD_IASACE_GetZoneInfoRespPayload;
```

where:

- u8ZoneID is the identifier of the zone
- u16ZoneType is a value indicating the type of zone (for the possible values, refer to the description of the attribute e``16ZoneType of the IAS Zone cluster in Section 37.2)
- u64IeeeAddress is the IEEE/MAC address of the device which hosts the zone
- sZoneLabel is a character string representing a name/label for the zone

E_CLD_IASACE_CMD_ZONE_STATUS_CHANGED Data

```
typedef struct
{
    zuint8                  u8ZoneID;
    zenum16                   eZoneStatus;
    zenum8                  eAudibleNotification;
    tsZCL_CharacterString     sZoneLabel;
} tsCLD_IASACE_ZoneStatusChangedPayload;
```

where:

- u8ZoneID is the identifier of the zone
- u16ZoneType is a value indicating the type of zone (for the possible values, refer to the description of the attribute e``16ZoneType of the IAS Zone cluster in Section 37.2)
- eAudibleNotification is a value specifying whether an audible notification

  (e.g. a chime) to signal the change is required (enumerations are available in teCLD_IASACE_AudibleNotification - see Section 38.8.4):

Value	Status
0x00	Audible notification to be muted
0x01	Audible notification to be sounded
0x02 - 0xFF	Reserved

- sZoneLabel is a character string representing a name/label for the zone

E_CLD_IASACE_CMD_PANEL_STATUS_CHANGED Data

```
tsCLD_IASACE_PanelStatusChangedOrGetPanelStatusRespPayload
```

For details of this structure, see Section 38.7.5.

E_CLD_IASACE_CMD_GET_PANEL_STATUS_RESP Data

```
tsCLD_IASACE_PanelStatusChangedOrGetPanelStatusRespPayload
```

For details of this structure, see Section 38.7.5.

E_CLD_IASACE_CMD_BYPASS_RESP Data

```
typedef struct
{
    zuint8          u8NumofZones;
    zuint8         *pu8BypassResult;
} tsCLD_IASACE_BypassRespPayload;
```

where:

- u8NumOfZones is the number of zones 'bypassed' (taken out of the system)
- pu8BypassResult is a pointer to a list of identifiers specifying the zones bypassed (the number of zones in the list is specified in u8NumOfZones)

E_CLD_IASACE_CMD_GET_ZONE_STATUS_RESP Data

```
typedef struct
{
    zbool           bZoneStatusComplete;
    zuint8          u8NumofZones;
    zuint8         *pu8ZoneStatus;
} tsCLD_IASACE_GetZoneStatusRespPayload;
```

where:

- bZoneStatusComplete is a Boolean indicating whether the current response completes the set of zones for which status information can be returned (if not, the client should send another Get Zone Status command to the server):
  - TRUE - no more zone status information to be returned
  - FALSE - status information for more zones available to be queried
- u8NumofZones is the number of zones for which status information was returned in this response
- pu8ZoneStatus is a pointer to a list of status values for the reported zones (the number of values in the list is indicated by u8NumofZones above) - each is a 24-bit value containing the following information:

Bits	Description
0-7	Zone ID
8-23	Value of b16ZoneStatus attribute of the IAS Zone cluster for the zone

Enumerations

teCLD_IASACE_ArmMode The following structure contains the enumerations used to indicate a mode of armament:

```
typedef enum
{
    E_CLD_IASACE_ARM_MODE_DISARM = 0x00,
    E_CLD_IASACE_ARM_MODE_ARM_DAY_HOME_ZONES_ONLY,
    E_CLD_IASACE_ARM_MODE_ARM_NIGHT_SLEEP_ZONES_ONLY,
    E_CLD_IASACE_ARM_MODE_ARM_ALL_ZONES,
} teCLD_IASACE_ArmMode;
```

Parent topic: Enumerations

teCLD_IASACE_PanelStatus The following structure contains the enumerations used to indicate the status of the panel:

```
typedef enum
{
    E_CLD_IASACE_PANEL_STATUS_PANEL_DISARMED = 0x00,
    E_CLD_IASACE_PANEL_STATUS_PANEL_ARMED_DAY,
    E_CLD_IASACE_PANEL_STATUS_PANEL_ARMED_NIGHT,
    E_CLD_IASACE_PANEL_STATUS_PANEL_ARMED_AWAY,
    E_CLD_IASACE_PANEL_STATUS_PANEL_EXIT_DELAY,
    E_CLD_IASACE_PANEL_STATUS_PANEL_ENTRY_DELAY,
    E_CLD_IASACE_PANEL_STATUS_PANEL_NOT_READY_TO_ARM,
    E_CLD_IASACE_PANEL_STATUS_PANEL_IN_ALARM,
    E_CLD_IASACE_PANEL_STATUS_PANEL_ARMING_STAY,
    E_CLD_IASACE_PANEL_STATUS_PANEL_ARMING_NIGHT,
    E_CLD_IASACE_PANEL_STATUS_PANEL_ARMING_AWAY
} teCLD_IASACE_PanelStatus;
```

Parent topic: Enumerations

teCLD_IASACE_AlarmStatus The following structure contains the enumerations used to indicate the status/meaning of the alarm:

```
typedef enum
{
    E_CLD_IASACE_ALARM_STATUS_NO_ALARM = 0x00,
    E_CLD_IASACE_ALARM_STATUS_BURGLAR,
    E_CLD_IASACE_ALARM_STATUS_FIRE,
    E_CLD_IASACE_ALARM_STATUS_EMERGENCY,
    E_CLD_IASACE_ALARM_STATUS_POLICE_PANIC,
    E_CLD_IASACE_ALARM_STATUS_FIRE_PANIC,
    E_CLD_IASACE_ALARM_STATUS_EMERGENCY_PANIC
} teCLD_IASACE_AlarmStatus;
```

Parent topic: Enumerations

teCLD_IASACE_AudibleNotification The following structure contains the enumerations used to indicate the configuration of the audible indication:

```
typedef enum
{
    E_CLD_IASACE_AUDIBLE_NOTIF_MUTE = 0x00,
    E_CLD_IASACE_AUDIBLE_NOTIF_DEFAULT_SOUND
} teCLD_IASACE_AudibleNotification;
```

Parent topic: Enumerations

Parent topic:*IAS Ancillary Control Equipment Cluster*

Compile-time options To enable the IAS ACE cluster in the code to be built, it is necessary to add the following to the **zcl_options.h** file:

```
#define CLD_IASACE
```

In addition, to include the software for a cluster client or server or both, it is necessary to add one of the following to the same file:

```
#define IASACE_SERVER
#define IASACE_CLIENT
```

The IAS ACE cluster contains macros that may be specified at compile-time by adding one or more of the following lines to the **zcl_options.h** file.

Maximum Size of Zone Table The maximum number of entries in a Zone table on the cluster server can be defined using the following line:

```
#define CLD_IASACE_ZONE_TABLE_SIZE n
```

where n is the desired maximum (e.g. 8).

Maximum Length of Arm/Disarm Code The maximum length of string allowed for the arm/disarm code can be defined using the following line:

```
#define CLD_IASACE_MAX_LENGTH_ARM_DISARM_CODE n
```

where n is the desired maximum.

Maximum Length of Zone Label The maximum length of string allowed for a zone name/label can be defined using the following line:

```
#define CLD_IASACE_MAX_LENGTH_ZONE_LABEL n
```

where n is the desired maximum.

Disable APS Acknowledgements for Bound Transmissions APS acknowledgements for bound transmissions from this cluster can be disabled using the following line:

```
#define CLD_IASACE_BOUND_TX_WITH_APS_ACK_DISABLED
```

Cluster Revision Add this line to define the value (n) of the Cluster Revision attribute:

```
#define CLD_IASACE_CLUSTER_REVISION <n>
```

The default value is 1, which corresponds to the revision of the cluster in the ZCL r6 specification (see Section 2.4).

Parent topic:*IAS Ancillary Control Equipment Cluster*

IAS Warning Device Cluster This chapter describes the IAS Warning Device (WD) cluster which provides an interface to a Warning Device in an IAS (Intruder Alarm System).

The IAS WD cluster has a Cluster ID of 0x0502.

Overview The IAS WD cluster provides an interface to an IAS Warning Device, allowing warning indications triggered by alarm conditions to be sent to it. The server side of the cluster is implemented on the IAS Warning Device and the client side is implemented on the triggering device. The IAS Warning Device is detailed in the *ZigBee Devices User Guide (JNUG3131)*.

To use the functionality of this cluster, you must include the file **IASWD.h** in your application and enable the cluster by defining CLD_IASWD in the **zcl_options.h** file.

The inclusion of the client or server software must be pre-defined in the compile-time options of the application. In addition, if the cluster resides on a custom endpoint, then the role of client or server must also be specified when creating the cluster instance.

The compile-time options for the IAS WD cluster are fully detailed in Section 39.7.

Parent topic:*IAS Warning Device Cluster*

IAS WD Structure and Attribute The structure definition for the IAS WD cluster is:

```
typedef struct
{
#ifdef IASWD_SERVER
  zuint16   u16MaxDuration;
#endif
  zuint16   u16ClusterRevision;
} tsCLD_IASWD;
```

where:

- u``16MaxDuration is the maximum duration, in seconds, for which the alarm can be continuously active (for example, a siren sounded). The range of possible values is 0 to 65534 seconds and the default value is 240 seconds.
- u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specification on which this cluster instance is based. The cluster specification in the ZCL r6 corresponds to a cluster revision of 1. The value is incremented by one for each subsequent revision of the cluster specification. This attribute is also described in Section 2.4.

Parent topic:*IAS Warning Device Cluster*

Issuing Warnings The IAS WD cluster allows a device which detects warning conditions (example, fire) to trigger a warning on an IAS Warning Device which, in turn, initiates a physical alarm such as a siren and/or strobe. The IAS Warning Device hosts the cluster server and the triggering device hosts the cluster client.

Two types of warning can be initiated:

- **Warning mode:** This mode indicates a genuine emergency, such as a fire or an intruder. On detection of the emergency condition, the application on the triggering device must call the **eCLD_IASWDStartWarningReqSend()** function, which sends a Start Warning command to the Warning Device. The payload of this command contains the time-duration for which

the Warning Device must remain in warning mode. The specified duration must not exceed the maximum duration defined in the u16MaxDuration attribute on the Warning Device (see Section 39.2). The payload also contains details of the warning and the strobe requirements, if any. On receiving this command, an E_CLD_IASWD_CMD_WD_START_WARNING event is generated on the Warning Device (see Section 39.4) for the attention of the application.

- **Squawk mode:** This mode indicates a change of state of the IAS system - that is, armed or disarmed. Thus, this is typically a short audible beep or 'squawk' that is emitted when the system is armed or disarmed. To initiate a squawk, the application on the triggering device must call the function **eCLD_IASWDSquawkReqSend()**, which sends a Squawk command to the Warning Device. The payload also contains details of the squawk and the strobe requirements, if any. On receiving this command, an E_CLD_IASWD_CMD_WD_SQUAWK event is generated on the Warning Device (see Section 39.4) for the attention of the application.

The payloads of the commands are detailed in Section 39.6.2.

Note: In order to maintain timing information on the cluster server, the application on the Warning Device must periodically call the **eCLD_IASWDUpdate()** function every 100 ms. These calls can be prompted using a software timer.

Note: The u16MaxDuration attribute on the Warning Device can be updated by the application on this device by calling the function **eCLD_IASWDUpdateMaxDuration()**.

Parent topic:*IAS Warning Device Cluster*

IAS WD Events The IAS WD cluster has its own events that are handled through the callback mechanism outlined in *Chapter 3*. If a device uses the IAS WD cluster then IAS WD event handling must be included in the callback function for the associated endpoint, where this callback function is registered through the relevant endpoint registration function (for example, through **eHA_RegisterWarningDeviceEndPoint()** for a Warning Device). The relevant callback function is then invoked when an IAS WD event occurs.

For an IAS WD event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsCLD_IASWDCallBackMessage structure:

```
typedef struct
{
  uint8   u8CommandId;
  union
  {
  tsCLD_IASWD_StartWarningReqPayload  *psWDStartWarningReqPayload;
  tsCLD_IASWD_SquawkReqPayload   *psWDSquawkReqPayload;
  tsCLD_IASWD_StrobeUpdate  *psStrobeUpdate;  /* Internal */
  tsCLD_IASWD_WarningUpdate   *psWarningUpdate; /* Internal */
  } uMessage;
} tsCLD_IASWDCallBackMessage;
```

When an IAS WD event occurs, one of several command types could have been received. The relevant command type is specified through the u8CommandId field of the tsSM_CallBackMessage structure. The possible command/event types are detailed in the table below (not that psStrobeUpdate and psWarningUpdate are for internal use only).

u8Comman Enumera-tion	Description
E_CLD_IASW	A Start Warning command has been received by the cluster server - this command requests that the alarm is activated for a specified time. The command payload is contained in the event in the tsCLD_IASWD_StartWarningReqPayload structure, described in Section 39.6.2.
E_CLD_IASW	A Squawk command has been received by the cluster server - this command requests that the alarm is briefly activated to emit a 'squawk' to indicate a status change, such as system disarmed. The command payload is contained in the event in the tsCLD_IASWD_SquawkReqPayload structure, described in Section 39.6.2.

Parent topic:*IAS Warning Device Cluster*

Functions The following IAS WD cluster functions are provided in the NXP implementation of the ZCL:

1. eCLD_IASWDCreateIASWD
2. eCLD_IASWDUpdate
3. eCLD_IASWDUpdateMaxDuration
4. eCLD_IASWDStartWarningReqSend
5. eCLD_IASWDSquawkReqSend

eCLD_IASWDCreateIASWD

```
teZCL_Status eCLD_IASWDCreateIASWD(
        tsZCL_ClusterInstance *psClusterInstance,
        bool_t bIsServer,
        tsZCL_ClusterDefinition *psClusterDefinition,
        void *pvEndPointSharedStructPtr,
        uint8 *pu8AttributeControlBits,
        tsCLD_IASWDCustomDataStructure
        *psCustomDataStructure);
```

Description This function creates an instance of the IAS WD cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function creates an IAS WD cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions.

Note: This function must not be called for an endpoint on which a standard ZigBee device is used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function.

When used, this function must be called after the stack has been started and after the ZCL has been initialized.

Parameters

- *psClusterInstance*: Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initializing individual structure fields.
- *bIsServer*: Type of cluster instance (server or client) to be created:
- TRUE - server
- FALSE - client
- *psClusterDefinition*: Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the IAS WD cluster. This parameter can refer to a pre-filled structure called sCLD_``IASWD which is provided in the **IASWarningDevice.h** file.
- *pvEndPointSharedStructPtr*: Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_IASWD which defines the attributes of IAS WD cluster. The function initializes the attributes with default values.
- *pu8AttributeControlBits*: Pointer to an array of **uint8** values, with one element for each attribute in the cluster.
- *psCustomDataStructure*: Pointer to a structure containing the storage for internal functions of the cluster (see Section 39.6.1)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_IASWDUpdate

```
teZCL_Status eCLD_IASWDUpdate(
uint8 u8SourceEndPoint);
```

Description This function can be used on an IAS WD cluster server to update the timing requirements of the Warning Device. The function should be called by the application at a rate of once every 100 ms.

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the IAS WD cluster resides

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Functions

eCLD_IASWDUpdateMaxDuration

```
teZCL_Status eCLD_IASWDUpdateMaxDuration(
uint8 u8SourceEndPointId,
uint16 u16MaxDuration);
```

Description This function can be used on an IAS WD cluster server to set the value of the u16MaxDuration attribute, which represents the maximum duration, in seconds, for which the alarm can be continuously active.

The set value is the maximum duration, in seconds, for which the alarm can be active following a received Start Warning request.

Parameters

- *u8SourceEndPointId*: Number of the endpoint on which the IAS WD cluster resides
- *u16MaxDuration*: Value to which attribute will be set, in the range 0 to 65534

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Functions

eCLD_IASWDStartWarningReqSend

```
teZCL_Status eCLD_IASWDStartWarningReqSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_IASWD_StartWarningReqPayload *psPayload);
```

Description This function can be used on IAS WD cluster client to send a Start Warning command to the IAS WD server on a Warning Device.

The receiving IAS WD server activates the alarm on the Warning Device for a specified duration.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP

- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload*: Pointer to a structure containing the payload for the command (see Section 39.6.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

eCLD_IASWDSquawkReqSend

```
teZCL_Status eCLD_IASWDSquawkReqSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_IASWD_SquawkReqPayload *psPayload);
```

Description This function can be used on IAS WD cluster client to send a Squawk command to the IAS WD server on a Warning Device.

The receiving IAS WD server will briefly activate the alarm on the Warning Device to emit a 'squawk' - depending on the device, this could be a visible and/or audible emission. The parameters of the squawk are specified in the command payload.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the request. This parameter is used both to send the command and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP

- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload*: Pointer to a structure containing the payload for the command (see Section 39.6.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_ZTRANSMIT_FAIL

If an error is returned by the ZigBee PRO stack function which is invoked by this function to transmit the data, this error may be obtained by calling **eZCL_GetLastZpsError()**.

Parent topic: Functions

Parent topic:*IAS Warning Device Cluster*

Structures

Custom Data Structure The IAS WD cluster requires extra storage space to be allocated to be used by internal functions. The structure definition for this storage is shown below:

```
typedef struct
{
 tsCLD_IASWD_SquawkReqPayload sSquawk;
 tsCLD_IASWD_StartWarningReqPayload sWarning;
 uint32   u32WarningDurationRemainingIn100MS;
 tsZCL_ReceiveEventAddress  sReceiveEventAddress;
 tsZCL_CallBackEvent  sCustomCallBackEvent;
 tsCLD_IASWDCallBackMessage sCallBackMessage;
} tsCLD_IASWD_CustomDataStructure;
```

The fields are for internal use and no knowledge of them is required.

Parent topic: Structures

Custom Command Payloads The following structures contain the payloads for the IAS WD cluster custom commands.

'Start Warning' Payload The following structure contains the payload of a Start Warning command.

```
typedef struct
{
 uint8   u8WarningModeStrobeAndSirenLevel;
 uint16  u16WarningDuration;
 uint8   uStrobeDutyCycle;
 enum8       eStrobeLevel;
}tsCLD_IASWD_StartWarningReqPayload;
```

where:

- u8WarningModeStrobeAndSirenLevel is an 8-bit bitmap containing the requirements for the warning alarm, as follows:

Bits	Description
0-3	Warning Mode - indicates the meaning of the requested warning:0 - Stop (no warning)1 - Burglar2 - Fire3 - Emergency4 - Police panic5 - Fire panic6 - Emergency (medical) panic All other values are reserved
4-5	Strobe* - indicates whether a visual strobe indication of the warning is required:0 - No strobe1 - Use strobeOther values are reserved
6-7	Siren Level - indicates the requested level of an audible siren (if enabled):0 - Low level1 - Medium level2 - High level3 - Very high level

* If 'Strobe' is 1 and 'Warning Mode' is 0, only the strobe is activated

- u16WarningDuration is the requested time-duration of the warning, in seconds, which must be less than or equal to the value of the u16MaxDuration attribute
- uStrobeDutyCycle is the duty-cycle of the strobe pulse, expressed as a percentage in 10% steps (example, 0x1E represents 30%) - invalid values are rounded to the nearest multiple of 10%
- eStrobeLevel is the level of the strobe (pulse)

'Squawk' Payload The following structure contains the payload of a Squawk command.

```
typedef struct
{
  uint8  u8SquawkModeStrobeAndLevel;
}tsCLD_IASWD_SquawkReqPayload;
```

Where u8SquawkModeStrobeAndLevel is an 8-bit bitmap containing the requirements for the 'squawk', as follows.

Bits	Description
0-3	Squawk Mode - indicates the meaning of the required 'squawk':0 - System is armed1 - System is disarmedAll other values are reserved
4	Strobe - indicates whether a visual strobe indication of the 'squawk' is required:0 - No strobe1 - Use strobe
5	Reserved
6-7	Squawk Level - indicates the requested level of the audible squawk sound:0 - Low level1 - Medium level2 - High level3 - Very high level

Parent topic: Structures

Event Data Structures The following structures hold the data contained in certain IAS WD cluster events.

E_CLD_IASWD_CLUSTER_UPDATE_STROBE Data

```
typedef struct
{
 bool_t    bStrobe;
 uint8     u8StrobeDutyCycle;
 zenum8    eStrobeLevel;
}tsCLD_IASWD_StrobeUpdate;
```

where:

```
bStrobe is the current (new) status of the strobe:
```

- TRUE - Strobe 'on'
- FALSE - Strobe 'off'
  - uStrobeDutyCycle is the duty-cycle of the strobe pulse, expressed as a percentage in 10% steps (example, 0x1E represents 30%) - invalid values is rounded to the nearest multiple of 10%
  - eStrobeLevel is the level (brightness) of the strobe pulse:
- 0 - Low level
- 1 - Medium level
- 2 - High level
- 3 - Very high level
  - All other values are reserved

E_CLD_IASWD_CLUSTER_UPDATE_WARNING Data

```
typedef struct
{
 uint8     u8WarningMode;
 uint16    u16WarningDurationRemaining;
 zenum8    eStrobeLevel;
}tsCLD_IASWD_WarningUpdate;
```

where:

- u8WarningMode is a value indicating the current warning mode:
  - 0 - No warning
  - 1 - Burglar
  - 2 - Fire
  - 3 - Emergency
  - 4 - Police panic
  - 5 - Fire panic
  - 6 - Emergency (medical) panic
    - All other values are reserved

- u16WarningDurationRemaining is the time, in seconds, during which the device remains in warning mode
- eStrobeLevel is the level of the strobe (pulse)

Parent topic: Structures

Parent topic:*IAS Warning Device Cluster*

Compile-time Options To enable the IAS WD cluster in the code to be built, it is necessary to add the following to the **zcl_options.h** file:

```
#define CLD_IASWD
```

In addition, to include the software for a cluster client or server or both, it is necessary to add one of the following to the same file:

```
#define IASWD_SERVER
#define IASWD_CLIENT
```

The IAS WD cluster contains macros that may be specified at compile-time by adding one or more of the following lines to the **zcl_options.h** file.

Add this line to define the value (n) of the Cluster Revision attribute:

```
#define CLD_IASWD_CLUSTER_REVISION <n>
```

The default value is 1, which corresponds to the revision of the cluster in the ZCL r6 specification (see Section 2.4).

Parent topic:*IAS Warning Device Cluster*

Part IX: Smart Energy Clusters This part comprises three chapters:

- *Chapter 40* details the **Price**cluster
- *Chapter 41* details the **Demand-Response and Load Control**cluster
- *Chapter 42* details the **Simple Metering** cluster

Price Cluster This chapter outlines the Price cluster, which is used to hold and exchange price information.

The Price cluster has a Cluster ID of 0x0700.

CAUTION:

Important: While the Price cluster software supports Block mode, this mode is not certifiable in SE 1.1.1 (07-5356-17) or earlier and is therefore not fully documented in this chapter. Customers who wish to use Block mode should contact NXP for direct support.

Overview The Price cluster is required in ZigBee devices as indicated in the table below.

	Server-side	Client-side
Mandatory in...	ESP	Smart Appliance
Optional in...		ESP Metering Device, IPD, PCT, Load Control Device

The ESP normally acts as the Price cluster server, holding price information received from the utility company. Other devices act as clients and receive price information from the ESP. The clients' price information must be kept up-to-date with the server's price information.

The Price cluster is enabled by defining CLD_PRICE in the **zcl_options.h** file. Further compile-time options for the Price cluster are detailed in Section 40.13.

The Price cluster can operate in a mode in which pricing is based on the time at which the consumption occurs - this is called Time-Of-Use (TOU) mode. The cluster allows up to fifteen price 'tiers', numbered 1 to 15, which correspond to different time periods. Each price tier is given a label, which is used to identify the tier - typical labels are "Normal", "Shoulder", "Peak", "Real-time Pricing" and "Critical Peak". The tiers must be numbered consecutively in price order, with Tier 1 being the cheapest.*Note that tiers 7 to 15 are not certifiable in SE 1.1.1 or earlier and are reserved for future use.*

The information that can potentially be stored in the Price cluster is organised into the following attribute sets: Tier Label, Block Threshold, Block Period, Commodity, Block Price Information, Billing Period Information. The attribute sets Block Threshold, Block Period, Block Price Information and Billing Period Information are reserved for future use (with Block mode). There is also a set of attributes exclusively for use on a Price cluster client.

The cluster includes commands for requesting and publishing (distributing) price information. The price information that is valid for a certain time is sent from the Price cluster server (ESP) to the Price cluster clients using **Publish Price**commands, which may be sent from the ESP under the following circumstances:

- Unsolicited from the server - for example, when new pricing information has been received from the utility company or a new price tier becomes active
- In response to a **Get Current Price** command, sent by a client that needs the price for the current time period
- In response to a **Get Scheduled Prices** command, sent by a client that needs both current and future prices

Functions are provided for implementing the cluster commands. These functions are referenced in Section 40.4 and Section 40.5, and detailed in Section 40.9.

Parent topic:*Price Cluster*

Price cluster structure and attributes The Price cluster is contained in the following tsCLD_Price structure:

```
typedef struct CLD_Price_tag
{
    /* Tier Price Label Set (D.4.2.2.1) */
#if (CLD_P_ATTR_TIER_PRICE_LABEL_MAX_COUNT != 0)
 tsZCL_OctetString  asTierPriceLabel[CLD_P_ATTR_TIER_PRICE_LABEL_MAX_COUNT];
 uint8  au8TierPriceLabel[CLD_P_ATTR_TIER_PRICE_LABEL_MAX_COUNT][SE_PRICE_SERVER_
↪MAX_STRING_LENGTH];
#endif
 /* Block Threshold Set (D.4.2.2) */
#if (CLD_P_ATTR_BLOCK_THRESHOLD_MAX_COUNT != 0)
 zuint48        au48BlockThreshold[CLD_P_ATTR_BLOCK_THRESHOLD_MAX_COUNT];
#endif
    /* Block Period Set (D.4.2.2.3) */
#ifdef CLD_P_ATTR_START_OF_BLOCK_PERIOD

where:

'Tier Label' Attribute Set

- The following are optional attributes that are only relevant to TOU mode**(*tiers 7 to 15 are not certifiable in SE 1.1.1 or earlier and are reserved for future use*):
  - asTierPriceLabel[CLD_P_ATTR_TIER_PRICE_LABEL_MAX_COUNT]

    is a tsZCL_OctetString structure containing information on tier labels. The maximum size of asTierPriceLabel is defined by assigning a value to CLD_P_ATTR_TIER_PRICE_LABEL_MAX_COUNT. This optional element is paired with au8TierPriceLabel (below)

  - au8TierPriceLabel[CLD_P_ATTR_TIER_PRICE_LABEL_MAX_COUNT]``[SE_PRICE_SERVER_MA is an array containing the tier labels, e.g. “Peak”. This optional element is paired with the element asTierPriceLabel (above)

Note: Memory space for each (enabled) price tier label is statically allocated and comprises 13 bytes per label (plus one byte for the ‘octet count’). Therefore, memory space remains allocated for unused bytes.

‘Block Threshold’ Attribute Set

- The following are optional attributes that relate to Block mode and are fully described in the *ZigBee Smart Energy Profile Specification*(*these attributes are not certifiable in SE 1.1.1 or earlier and are for future use*):

```
au48BlockThreshold[CLD_P_ATTR_BLOCK_THRESHOLD_MAX_COUNT]
```

‘Block Period’ Attribute Set

- The following are optional attributes that relate to Block mode and are fully described in the *ZigBee Smart Energy Profile Specification*(*these attributes are not certifiable in SE 1.1.1 or earlier and are for future use*):
  - utctStartOfBlockPeriod
  - u24BlockPeriodDuration
  - u24ThresholdMultiplier
  - u24ThresholdDivisor

‘Commodity’ Attribute Set

- The following are optional attributes:
  - e8CommodityType is an enumeration representing the type of commodity (e.g. gas) to which the prices apply - the enumerations used are those provided in the teCLD_SM_MeteringDeviceType structure of the Simple Metering cluster and listed in Section 42.10.6
  - u32StandingCharge is the value of a fixed daily ‘standing charge’ associated with supplying the commodity, expressed in the currency and with the decimal places indicated in the Publish Price command described in Section 40.11.1 (the value 0xFFFFFFFF indicates that the field is not used)
  - u32ConversionFactor is used only for gas and accounts for the variation of gas volume with temperature and pressure (and is dimensionless). The Price server can change this conversion factor at any time and this attribute contains the currently active value. The default value is 1. The position of the decimal point is indicated by b8``ConversionFactorTrailingDigit described below.
  - b8``ConversionFactorTrailingDigit is an 8-bit bitmap which indicates the location of the decimal point in the u32ConversionFactor attribute. The most significant 4 bits indicate the number of digits after the decimal point. The remaining bits are reserved.
  - u32CalorificValue is used only for gas and indicates the quantity of energy in MJ that is generated per unit volume or unit mass of gas burned (see e8``CalorificValueUnit) - the value can be used to calculate energy consumption in kWh. The position of the decimal point is indicated by b8``CalorificValueTrailingDigit described below.

  - e8``CalorificValueUnit is an enumerated value indicating whether u32CalorificValue is quantified per unit volume or per unit mass. The possible values are 0x01 for MJ/m3 and 0x02 for MJ/kg (all other values are reserved).
  - b8``CalorificValueTrailingDigit is an 8-bit bitmap which indicates the location of the decimal point in the u32CalorificValue attribute. The most significant 4 bits indicate the number of digits after the decimal point. The remaining bits are reserved.

'Block Price Information' Attribute Set

- The following are optional attributes that relate to Block mode and are fully described in the *ZigBee Smart Energy Profile Specification*(*these attributes are not certifiable in SE 1.1.1 or earlier and are for future use*):

```
au32NoTierBlockPrice[CLD_P_ATTR_NO_TIER_BLOCK_PRICES_MAX_COUNT]
au32Tier1BlockPrice[CLD_P_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_PRICE]
au32Tier2BlockPrice[CLD_P_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_PRICE]
au32Tier3BlockPrice[CLD_P_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_PRICE]
au32Tier4BlockPrice[CLD_P_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_PRICE]
au32Tier5BlockPrice[CLD_P_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_PRICE]
au32Tier6BlockPrice[CLD_P_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_PRICE]
au32Tier7BlockPrice[CLD_P_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_PRICE]
au32Tier8BlockPrice[CLD_P_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_PRICE]
au32Tier9BlockPrice[CLD_P_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_PRICE]
au32Tier10BlockPrice[CLD_P_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_PRICE]
au32Tier11BlockPrice[CLD_P_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_PRICE]
au32Tier12BlockPrice[CLD_P_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_PRICE]
au32Tier13BlockPrice[CLD_P_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_PRICE]
au32Tier14BlockPrice[CLD_P_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_PRICE]
au32Tier15BlockPrice[CLD_P_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_PRICE]
```

'Billing Period Information' Attribute Set

- The following are optional attributes that relate to Block mode (*both attributes are not certifiable in SE 1.1.1 or earlier and are for future use*):

```
utctStartOfBillingPeriod
u24BillingPeriodDuration
```

Client Attribute Set

- The following set of attributes are only for use on a Price cluster client:
  - u8ClientIncreaseRandomize represents the maximum length of time, in minutes, between a client node applying a price increase and taking a resulting action (such as reducing its power consumption). The action may be performed before or after the price increase is implemented, and the delay (either way) must be chosen at random by the application on the node. The maximum is set in minutes, in the range 0 to 60 minutes, but it is recommended that the random delay is selected in seconds.
  - u8ClientDecreaseRandomize represents the maximum length of time, in minutes, between a client node applying a price decrease and taking a resulting action (such as switching itself on). The action may be performed before or after the price decrease is implemented, and the delay (either way) must be chosen at random by the application on the node. The maximum is set in minutes, in the range 0 to 60 minutes, but it is recommended that the random delay is selected in seconds.

– e8ClientCommodityType is an enumeration representing the commodity that is priced on the client device. This enumeration is one from the 'Metering Device Type' enumerations listed in Table74.

Note: Price information for Time-Of-Use (TOU) mode is held in the tsSE_PricePublishPriceCmdPayload structure described in Section 40.11.1. Prices are matched to tiers using the strings defined in the Tier Label attributes.

Parent topic:*Price Cluster*

Attribute settings The Price cluster structure (see Section 40.2) contains no mandatory elements. All elements are optional, each being enabled/disabled through a corresponding macro defined in the **zcl_options.h** file - for example, the commodity type attribute is enabled/disabled through the macro CLD_P_ATTR_COMMODITY_TYPE. The attributes that are used depend on the number of tiers implemented (and Block mode attributes must be disabled).

Note:

- The Tier Label attributes are connected to the tier-related attributes in the Simple Metering cluster, e.g. u48CurrentTier6SummationDelivered for Tier 6. For a complete list of these Simple Metering attributes, refer to Section 42.2.
- The price information for Time-Of-Use (TOU) mode is stored in the structure tsSE_PricePublishPriceCmdPayload described in Section 40.11.1.

Parent topic:*Price Cluster*

Initializing and maintaining price lists A list of prices is held on both the Price cluster server (ESP) and client(s). The price list on a client must be maintained to mirror the price list on the server. On device startup, the Price cluster software initializes the device's price list as empty. The price lists are then built and maintained as described below.

The ESP receives price information from the utility company and populates its price list with this information. The application on the ESP does this by calling the function **eSE_PriceAddPriceEntry()** for each new price received from the utility company. This function also sends out a Publish Price command containing the new price information to all Price cluster clients in the network. On receiving this command, a Price cluster client automatically adds this price information to its own price list (see Section 40.5.1). However, at ESP startup, there may be no other active nodes in the network to receive the Publish Price commands (since the ESP is normally also the ZigBee Co-ordinator and is, therefore, the first node to be started). For this reason, the Price cluster clients should normally request the scheduled prices from the ESP when they start up, as described in Section 40.5.3.

Note: When initializing the price list at ESP startup, the ESP application should call **eSE_PriceAddPriceEntry()** with the address mode parameter set to E_ZCL_AM_NO_TRANSMIT, so that the price additions are not subsequently transmitted.

Note: A Price cluster server should take precautions to prevent clients from attempting to read the server price list during ESP initialization, before the prices have been received from the utility company. This can be achieved by adding the obtained prices to the server price list after the call to the relevant endpoint registration function (for example, **eSE_RegisterEspEndPoint()**) but before the call **to ZPS_eAplZdoStartStack()**.

A price list is maintained in time order and if there is an active price, it is positioned at the head of the list (with index 0). Price lists on clients are updated to reflect the price list on the server, as described in Section 40.5.

Note: The Price cluster of ZigBee Smart Energy automatically deletes a price entry from a client or server price list immediately after the price event has expired. This is because the start-time of a price event is a universal time (UTC) and therefore corresponds to a one-off event. In practice, the price list may need a new price schedule daily, which may be provided by the utility company.

Alternatively, if a similar schedule is required every day, the ESP application can keep a local copy of the schedule, which it can modify (e.g. start-times) and add to the price list on a daily basis.

The active price is always at the head of the price list (entry zero). The application should check that the entry at the head of the list is active before displaying it as the current price. If it is not active, a message may be displayed indicating that the current price is not known. The item at the head of the list is active if both of the following hold:

- Its start time is less than or equal to the current time, obtained by **u32ZCL_GetUTCTime()**
- The time on the client has been synchronized, i.e. a call to **bZCL_GetTimeHasBeenSynchronised()** returns TRUE

In addition to the function **eSE_PriceAddPriceEntry()**, the following functions allow an ESP application to access and manipulate its price list:

- **eSE_PriceGetPriceEntry()** obtains the price entry with the specified index.
- **eSE_PriceDoesPriceEntryExist()** checks whether there is a price entry with the specified start-time.
- **eSE_PriceRemovePriceEntry()** deletes the price entry with the specified start-time.
- **eSE_PriceClearAllPriceEntries()** deletes all price entries in the list.

These functions are fully detailed in Section 40.9.

Parent topic:*Price Cluster*

Publishing price information This section and its sub-sections describe the ways in which price information can be published (distributed) in a ZigBee network. As introduced in Section 40.1, there are three ways in which price information may be published to the network from the Price cluster server (ESP):

- Unsolicited unicasts - refer to Section 40.5.1
- Response to a Get Current Price command - refer to Section 40.5.2
- Response to a Get Scheduled Prices command - refer to Section 40.5.3

All of the above methods require the ESP to send a Publish Price command to the relevant device(s), where the payload of this command includes information such as resource (for example, gas), unit of measure, currency, price, current time, start-time, and duration. On receipt of this command, if valid, the received price information is automatically added to the price list on the device. If it is successfully added, an E_SE_PRICE_TABLE_ADD event is generated on the receiving device and this event is handled by the callback function registered for the relevant endpoint.

Unsolicited Price Updates When the ESP receives updated price information from the utility company (via the backhaul network) or a new price tier becomes active, the ESP must inform all network devices that are using the Price cluster. The ESP therefore individually unicasts a Publish Price command to all these devices. This command is sent out automatically - there is no need for the application on the ESP to explicitly send the command. In the case of new prices received from the utility company, the ESP application must call the function **eSE_PriceAddPriceEntry()** to add the new price to the price list held by the server, and the Publish Price command is then automatically sent out (possibly with a 'start-time of now'). Note that if the stack has not been started when **eSE_PriceAddPriceEntry()** is called, the function's address mode parameter should be set to E_ZCL_AM_NO_TRANSMIT, so that no transmission is attempted.

It is recommended that price updates on the ESP are relayed to Price cluster clients with which the ESP has been (previously) bound.

Note: Each of these bindings is initiated on the client node (e.g. IPD) using the ZigBee PRO stack function **ZPS_eAplZdpBindUnbindRequest()** to add the client's address and endpoint to the Binding table on the ESP. Binding is described in the *ZigBee 3.0 Stack User Guide (JNUG3130)*.

Therefore, when updating its price list, the ESP application should call **eSE_PriceAddPriceEntry()** with the address mode parameter set to E_ZCL_AM_BOUND, so that the price updates are transmitted only to bound endpoints/nodes.

As an alternative to using binding, the ESP can maintain a list of network nodes that are able to receive unsolicited Publish Price commands at all times - that is, nodes with radio receivers that remain active during idle periods (e.g. when sleeping). Unsolicited updates are then only sent to clients in this group. The ESP gathers information for this group from the Get Current Price commands received from clients (see Section40.5.2). This option requires the address node parameter to be set to ZPS_E_APL_AF_BROADCAST_RX_ON in **eSE_PriceAddPriceEntry()**.

The ESP can send unsolicited Publish Price commands with 'start-time of now' when an E_SE_PRICE_TABLE_ACTIVE event indicates that a new price has become active (see Section 40.8). This command can be used by devices that do not implement a real-time clock.

Parent topic: Publishing price information

Get Current Price Any device which supports the Price cluster can request the currently active price information from the ESP by sending a Get Current Price command. The function **eSE_PriceGetCurrentPriceSend()** allows a Price cluster client to send this command to the Price cluster server and deal with the response.

- On receiving the command, the server automatically responds with a Publish Price command containing the requested price information.
- On receiving the response, the client checks whether the received price information is currently in the client's price list. If it is not, the client adds the new price information to the list and generates an E_SE_PRICE_TABLE_ADD event - this event is handled by the callback function registered for the relevant endpoint.

The Get Current Price command contains information on whether the radio receiver of the sending device remains active when the node is otherwise idle (e.g. sleeping). If this is true, the ESP application can use the address of the node to update a list of such devices, which it may use when sending out unsolicited Publish Price commands (see Section 40.5.1). The ESP application can extract this information from the event E_SE_PRICE_GET_CURRENT_PRICE_RECEIVED which is generated when a Get Current Price command is received by the server - this event is handled by the callback function registered for the relevant endpoint.

Parent topic: Publishing price information

Get Scheduled Prices Any device which supports the Price cluster can request the current price schedule from the ESP by sending a Get Scheduled Prices command - the schedule includes a set of prices with their start-times and durations. The function **eSE_PriceGetScheduledPricesSend()** allows a Price cluster client to send this command to the Price cluster server and deal with the responses.

- On receiving the command, the server automatically responds with a sequence of Publish Price commands, where each of these responses contains the information for one scheduled price.
- On receiving a response, the client checks whether the received price information is currently in the client's price list. If it is not, the client adds the new price information to the list and generates an E_SE_PRICE_TABLE_ADD event - this event is handled by the callback function registered for the relevant endpoint.

Parent topic: Publishing price information

Parent topic:*Price Cluster*

Time-synchronization via Publish Price commands As an alternative to using the Time cluster to time-synchronize a ZigBee device with the ESP (as described in Section 18.5.3), the local application can use the time embedded in a Publish Price command from the ESP (see Section 40.5), as described below.

Note: A device that implements the Price cluster must also implement the Time cluster.

It is the responsibility of the application on a ZigBee device to perform time-synchronization with the ESP. This involves updating the ZCL time on the local device.

The initialization of the ZCL time on a device should be performed using the Time cluster by requesting the current time from the ESP, as described in Section 18.5.2 (this method also gets the time-zone and daylight saving information).

Subsequent re-synchronizations of a device with the time-master can use the time contained in Publish Price commands from the ESP (but note that no time-zone or daylight saving information is included). Therefore, a device can update its ZCL time whenever it receives a Publish Price command. On receiving this command, a 'data indication' stack event is generated, which causes a ZCL user task to be activated. The event is initially handled by this task as described in *Chapter 3*, resulting in an E_ZCL_ZIGBEE_EVENT event being passed to the ZCL via **vZCL_EventHandler()**. The ZCL invokes the relevant user-defined callback function (see *Chapter 3*) which, provided that the event is of the type E_SE_PRICE_TIME_UPDATE, must update the ZCL time using **vZCL_SetUTCTime()**.

Note that the utctTime field of the local copy of the Time cluster is not updated, since this should only be done following a read of the Time cluster attributes from the server.

CAUTION:

If a device is handling Publish Price commands from more than one server, the time must only be updated with time events from one server, to prevent the time from jittering forwards and backwards if the servers' times are not in sync.

The time-synchronization of a device (with the time-master) should be performed regularly. As a rule, if no Publish Price commands have been received from the ESP in the last 48 hours, the device should request the current time from the ESP and update its own times as described in Section 18.5.3.

It is worth noting that an undefined ZCL time causes the following issues in the Price cluster:

- A Price cluster server without a ZCL time cannot issue any Publish Price commands, since the current time is a mandatory field of this command.
- A Price cluster client without a ZCL time cannot process a Publish Price command with a 'start-time of now', unless the ZCL time is first set with the time extracted from the received command.
- If the price at the head of the price list has a specified start-time, it is not possible to know whether this price is active or not.

Regarding the last point, a device should be time-synchronized with the ESP (as described in Section 18.5.2) before an attempt is made to add scheduled prices to the device's price list. Then, if the device receives a scheduled price with a 'start-time of now', it is permissible to add this price to the list.

Parent topic:*Price Cluster*

Conversion factor and calorific value (gas only) The Price cluster provides attributes related to conversion factor and calorific value for use with gas (only):

- **Conversion factor:** Accounts for the variation of gas volume with temperature and pressure
- **Calorific value:** Indicates the quantity of energy in MJ that is generated per unit volume or unit mass of gas burned

The attributes associated with the above properties are part of the 'Commodity' set - refer to Section 40.2.

If required, conversion factor and/or calorific value must be enabled in the compile-time options, as described in Section 40.13.

Conversion factors and calorific values can be independently scheduled with associated start-times. The Price cluster server (ESP) and clients each maintain a list of the scheduled conversion factors and a list of the scheduled calorific values (along with their start-times). The maximum number of entries in each list is by default 2 (allowing the present one and the next one to be stored), but this maximum can be re-defined in the compile-time options.

The ESP (Price cluster server) receives a scheduled conversion factor or calorific value from the utility company. A received value and its associated start-time are added as an entry to the relevant list on the server by the ESP application as follows:

- A new entry is added to the conversion factor list by calling the function **eSE_PriceAddConversionFactorEntry()**
- A new entry is added to the calorific value list by calling the function **eSE_PriceAddCalorificValueEntry()**

The entries are maintained in the list in increasing order of start-times. If an existing entry in the list has the same start-time as the new entry, the entry with the greater value of the Issuer Event ID is included in the list (and the other entry is discarded).

Once a new entry is added to a list on the server, a Publish Conversion Factor or Publish Calorific Value command is automatically sent to the cluster clients to inform them that a new value is available, allowing them to update their lists with the new information.

Initializing Conversion Factors and Calorific Values at Network Startup Note the following issues at network startup:

- When the ESP node first starts, there may be no other active nodes in the network to receive a new conversion factor and/or calorific value. Thus, the Price cluster clients should request this information from the ESP when they start. They can do this using **eSE_PriceGetConversionFactorSend()** or **eSE_PriceGetCalorificValueSend()**, as appropriate.
- When initializing the conversion factor or calorific value at ESP startup, the ESP application should call **eSE_PriceAddConversionFactorEntry()** or **eSE_PriceAddCalorificValueEntry()** with the address mode parameter set to E_ZCL_AM_NO_TRANSMIT. This prevents the new value from being transmitted to a network with no other active nodes.
- Any clients that are active during ESP initialization should not request a conversion factor or calorific value from the ESP before the values are received from the utility company. To avoid this problem, the ESP application should obtain the values from the utility company before calling the ZigBee PRO function **ZPS_eAplZdoStartStack()** and after calling the relevant endpoint register function (example, **eSE_RegisterEspMeterEndPoint()**).

Parent topic:*Price Cluster*

Price events The Price cluster has its own events that are handled through the callback mechanism described in *Chapter 3*. If a device uses the Price cluster then Price event handling must be included in the callback function for the associated endpoint, where this callback function is registered through the relevant endpoint registration function (for example, through **eSE_RegisterEspEndPoint()** for a standalone ESP). The relevant callback function will then be invoked when a Price event occurs.

For a Price event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCus-

tomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to a tsSE_PriceCallBackMessage structure which contains the Price parameters:

```
typedef struct
{
 teSE_PriceCallBackEventType       eEventType;
 uint32              u32CurrentTime;
 union {
  tsSE_PriceTableCommand          sPriceTableCommand;
  tsSE_PriceTableTimeEvent         sPriceTableTimeEvent;
  teSE_PriceCommandOptions          ePriceCommandOptions;
  tsSE_PriceAckCmdPayload          *psAckCmdPayload;
  tsSE_PriceAttrReadInput          sReadAttrInfo;
  tsSE_BlockPeriodTableTimeEvent       sBlockPeriodTableTimeEvent;
  tsSE_ConversionFactorTableTimeEvent     sConversionFactorTableTimeEvent;
  tsSE_CalorificValueTableTimeEvent       sCalorificValueTableTimeEvent;
  } uMessage;
} tsSE_PriceCallBackMessage;
```

The eEventType field of the above structure specifies the type of Price event that has been generated - these event types are listed and described below (also refer to Section 40.12.2 for a summary of the Price events).

Note: The field sReadAttrInfo is reserved for future use (for Block mode).

E_SE_PRICE_TABLE_ADD The E_SE_PRICE_TABLE_ADD event is generated on a Price cluster client when an attempt has been made to add a scheduled price (received in a Publish Price command) to the local price list. In the tsSE_PriceCallBackMessage structure, the u32CurrentTime field is set to the current time from the Publish Price command and the sPriceTableCommand field is used as follows:

```
typedef struct {
   teSE_PriceStatus ePriceStatus;
} tsSE_PriceTableCommand;
```

ePriceStatus contains E_SE_PRICE_SUCCESS if a new price has been successfully added to the price list. Otherwise, the addition was rejected for the reason specified by ePriceStatus. If the addition was successful but the new price information overlapped (in time) any existing price information in the list, this previous price information may have been deleted from the list according to the rules in the ZigBee SE Profile specification.

E_SE_PRICE_TABLE_ACTIVE The E_SE_PRICE_TABLE_ACTIVE event is generated when there is a new active price or the active price expires. This event can occur due to a time update or the reception of a Publish Price command from the server. In the tsSE_PriceCallBackMessage structure, the u32CurrentTime field is set to the current ZCL time and the sPriceTableTimeEvent field is used as follows:

```
typedef struct {
   teSE_PriceStatus  ePriceStatus;
   uint8     u8NumberOfEntriesFree;
} tsSE_PriceTableTimeEvent;
```

ePriceStatus contains E_SE_PRICE_SUCCESS if there is a new active price or E_SE_PRICE_TABLE_NOT_YET_ACTIVE if the price at the head of the list is scheduled for a time in the future.

u8NumberOfEntriesFree contains the number of free entries in the client's price list. This number can be used to determine whether the client should issue a new Get Scheduled Prices command, in order to obtain more price entries to fill the free space in the list.

E_SE_PRICE_GET_CURRENT_PRICE_RECEIVED The E_SE_PRICE_GET_CURRENT_PRICE_RECEIVED event is generated on a Price cluster server when a Get Current Price command is received from a client. In the tsSE_PriceCallBackMessage structure, the ePriceCommandOptions field is used as follows:

```
typedef enum PACK
{
    E_SE_PRICE_REQUESTOR_RX_ON_IDLE = 0x01 // LSB set
} teSE_PriceCommandOptions;
```

This field indicates whether the client that sent the request has its radio receiver enabled when idle (e.g. sleeping), and is used as described in Section 40.5.1 and Section 40.5.2.

E_SE_PRICE_TIME_UPDATE The E_SE_PRICE_TIME_UPDATE event is generated on a Price cluster client when a Publish Price command is received from the server. In the tsSE_PriceCallBackMessage structure, the u32CurrentTime field is set to the current time from the Publish Price command. The application may then use this information to time-synchronise the device, as described in Section 40.6.

E_SE_PRICE_ACK_RECEIVED The E_SE_PRICE_ACK_RECEIVED event is generated on a Price cluster server when a Price Acknowledgment command is received from a client. In the tsSE_PriceCallBackMessage structure, the psAckCmdPayload field is a pointer to the structure tsSE_PriceAckCmdPayload defined as follows:

```
typedef struct {
    uint32              u32ProviderId;
    uint32              u32IssuerEventId;
    uint32              u32PriceAckTime;
    uint8               u8Control;
} tsSE_PriceAckCmdPayload;
```

This structure contains the Price Acknowledgement command payload.

E_SE_PRICE_NO_PRICE_TABLES The E_SE_PRICE_NO_PRICE_TABLES event is generated when an active price expires, is deleted from the price list and the price list becomes empty. In the tsSE_PriceCallBackMessage structure the sPriceTableTimeEvent field is used as follows:

```
typedef struct {
    teSE_PriceStatus ePriceStatus;
    uint8 u8NumberOfEntriesFree;
} tsSE_PriceTableTimeEvent;
```

ePriceStatus contains E_SE_PRICE_NO_TABLES.

u8NumberOfEntriesFree contains the number of free entries in the client's price list. This number can be used to determine whether the client should issue a new Get Scheduled Prices command, in order to obtain more price entries to fill the free space in the list.

E_SE_PRICE_CONVERSION_FACTOR_TABLE_ACTIVE The E_SE_PRICE_CONVERSION_FACTOR_TABLE_ACTIV event is generated when a new conversion factor value becomes active - that is, when the start-time of the conversion factor entry becomes less than or equal to the present time. This event can occur due to a time update or the reception of a Publish Conversion Factor command from the server.

In the tsSE_PriceCallBackMessage structure, the u32CurrentTime field is set to the current ZCL time and the field tsSE_PriceConversionFactorTableTimeEvent is used as follows:

```
typedef struct {
   teSE_PriceStatus     eConversionFactorStatus;
   uint8          u8NumberOfEntriesFree;
} tsSE_ConversionFactorTableTimeEvent;
```

eConversionFactorStatus takes the value E_ZCL_SUCCESS when a new conversion factor becomes active.

u8NumberOfEntriesFree contains the present number of free entries in the conversion factor list. This value should be checked by the client before issuing a Get Conversion Factor command to obtain a new conversion factor value - the command should be issued only if there is free space in the list for a new entry to be added.

E_SE_PRICE_CONVERSION_FACTOR_ADD The E_SE_PRICE_CONVERSION_FACTOR_ADD event is generated when a new conversion factor entry is advertised by the ESP to the client application using the Publish Conversion Factor command. Note that the event is generated even when the new entry is not successfully added to the internal conversion factor list maintained by the cluster.

The status of the command is passed back to the user application in the ePriceStatus field of the tsSE_PriceTableCommand structure (see above) within the tsSE_PriceCallBackMessage structure.

E_SE_PRICE_CALORIFIC_VALUE_TABLE_ACTIVE The E_SE_PRICE_CALORIFIC_VALUE_TABLE_ACTIVE event is generated when a new calorific value becomes active - that is, when the start-time of the calorific value entry becomes less than or equal to the present time. This event can occur due to a time update or the reception of a Publish Calorific Value command from the server.

In the tsSE_PriceCallBackMessage structure, the u32CurrentTime field is set to the current ZCL time and the field tsSE_PriceCalorificValueTableTimeEvent is used as follows:

```
typedef struct {
   teSE_PriceStatus    eCalorificValueStatus;
   uint8        u8NumberOfEntriesFree;
} tsSE_CalorificValueTableTimeEvent;
```

eCalorificValueStatus takes the value E_ZCL_SUCCESS when a new calorific value becomes active.

u8NumberOfEntriesFree contains the present number of free entries in the calorific value list. This value should be checked by the client before issuing a Get Calorific Value command to obtain a new calorific value - the command should be issued only if there is free space in the list for a new entry to be added.

E_SE_PRICE_CALORIFIC_VALUE_ADD The E_SE_PRICE_CALORIFIC_VALUE_ADD event is generated when a new calorific value entry is advertised by the ESP to the client application using the Publish Calorific Value command. Note that this event is generated even when the new entry is not successfully added to the internal calorific value list maintained by the cluster.

The status of the command is passed back to the user application in the ePriceStatus field of the tsSE_PriceTableCommand structure (see above) within the tsSE_PriceCallBackMessage structure.

Parent topic:*Price Cluster*

Functions The following Price cluster functions are provided:

- eSE_PriceCreate
- eSE_PriceGetCurrentPriceSend
- eSE_PriceGetScheduledPricesSend
- eSE_PriceAddPriceEntry
- eSE_PriceAddPriceEntryToClient
- eSE_PriceGetPriceEntry
- eSE_PriceDoesPriceEntryExist
- eSE_PriceRemovePriceEntry
- eSE_PriceClearAllPriceEntries
- eSE_PriceAddConversionFactorEntry
- eSE_PriceGetConversionFactorSend
- eSE_PriceGetConversionFactorEntry
- eSE_PriceDoesConversionFactorEntryExist
- eSE_PriceRemoveConversionFactorEntry
- eSE_PriceClearAllConversionFactorEntries
- eSE_PriceAddCalorificValueEntry
- eSE_PriceGetCalorificValueSend
- eSE_PriceGetCalorificValueEntry
- eSE_PriceDoesCalorificValueEntryExist
- eSE_PriceRemoveCalorificValueEntry
- eSE_PriceClearAllCalorificValueEntries

eSE_PriceCreate

```
teSE_PriceStatus eSE_PriceCreate(
        bool_t bIsServer,
        uint8 u8NumberOfRecordEntries,
        uint8 *pu8AttributeControlBits,
        uint8 *pau8RateLabel,
        tsZCL_ClusterInstance *psClusterInstance,
        tsZCL_ClusterDefinition *psClusterDefinition,
        tsSE_PriceCustomDataStructure
        *psCustomDataStructure,
        tsSE_PricePublishPriceRecord
        *psPublishPriceRecord,
        void *pvEndPointSharedStructPtr);
```

Description This function creates an instance of the Price cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device).

This function will create a Price cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions. For more details of creating cluster instances on custom endpoints, refer to *Appendix D.*

Note: This function must not be called for an endpoint on which a standard ZigBee device (e.g. IPD) will be used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function from those described in the *ZigBee Devices User Guide (JNUG3131)*

When used, this function must be the first Price cluster function called in the application, and must be called after the stack has been started and after the ZCL has been initialized.

The function requires an array to be declared for internal use, which contains one element (of type **uint8**) for each attribute of the cluster. The array length should therefore equate be the total number of attributes supported by the Price cluster, which can be obtained by using the macro PRICE_NUM_OF_ATTRIBUTES.

The array declaration should be as follows:

```
uint8 au8AppPriceClusterAttributeControlBits[PRICE_NUM_OF_ATTRIBUTES];
```

The function initializes the array elements to zero.

The function also requires an array of price labels to be declared, in which each array element is a label (string) for each price in the price list. The required declarations are different for a cluster server and client, as follows:

```
uint8 au8RateLabel[SE_PRICE_NUMBER_OF_CLIENT_PRICE_RECORD_ENTRIES][SE_PRICE_
↪CLIENT_MAX_STRING_LENGTH];
uint8 au8RateLabel[SE_PRICE_NUMBER_OF_CLIENT_PRICE_RECORD_ENTRIES][SE_PRICE_
↪CLIENT_MAX_STRING_LENGTH];
```

Parameters

- *bIsServer* Type of cluster instance (server or client) to be created:
- TRUE - server
- FALSE - client
- *u8NumberOfRecordEntries* Number of prices that can be stored in the price list, one of:
- SE_PRICE_NUMBER_OF_SERVER_PRICE_RECORD_ENTRIES
- SE_PRICE_NUMBER_OF_CLIENT_PRICE_RECORD_ENTRIES
- *pu8AttributeControlBits* Pointer to an array of **uint8** values, with one element for each attribute in the cluster (see above).
- *pau8RateLabel* Pointer to an array of price labels (strings), with one element for each price in the price list (see above).
- *psClusterInstance* Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initialising individual structure fields.
- *psClusterDefinition* Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the Price cluster. This parameter can refer to a pre-filled structure called sCLD_Price which is provided in the **Price.h** file.
- *psCustomDataStructure* Pointer to structure which contains custom data for the Price cluster. This structure is used for internal data storage. No knowledge of the fields of this structure is required

- *pvEndPointSharedStructPtr* Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_Price which defines the attributes of Price cluster. The function initializes the attributes with default values.

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eSE_PriceGetCurrentPriceSend

```
teZCL_Status eSE_PriceGetCurrentPriceSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    teSE_PriceCommandOptions ePriceCommandOptions);
```

Description This function can be used on a Price cluster client to send a Get Current Price command to the Price cluster server. Therefore, it is used by a device (such as an IPD) to obtain the currently active price from the ESP.

The ESP should respond with a Publish Price command containing the active price. This response is processed by the Price cluster. The obtained price is checked against the prices currently in the price list on the client. If the price is not currently in the list, it is added to the list and an E_SE_PRICE_TABLE_ADD event is generated to indicate that a price has been added.

A pointer must be specified to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which the request is sent
- *u8DestinationEndPointId* Number of the remote endpoint to which the request is sent
- *psDestinationAddress* Pointer to a structure containing the address of the remote node to which the request is sent
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the request
- *ePriceCommandOptions* Indicates whether the radio receiver on client remains on when the device is idle (for example, asleep):
  - 0x01 - receiver on when idle
  - 0x00 - receiver off when idle
- An enumeration is provided for the ‘on’ case:
- E_SE_PRICE_REQUESTOR_RX_ON_IDLE

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL

Parent topic: Functions

eSE_PriceGetScheduledPricesSend

```
teZCL_Status eSE_PriceGetScheduledPricesSend(
        uint8 u8SourceEndPointId,
        uint8 u8DestinationEndPointId,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        uint32 u32StartTime,
        int8 u8NumberOfEvents);
```

Description This function can be used on a Price cluster client to send a Get Scheduled Prices command to the Price cluster server. Therefore, it is used by a device (such as an IPD) to obtain the current price schedule from the ESP, either to check that its own price schedule is up-to-date or to recover the price schedule following a device reset.

You must specify the earliest start-time for the scheduled prices to be included in the results. This is normally set to zero or the current time (UTC). Note that you are not advised to specify the last time in the client price list, since the server may contain updates for prices covering an earlier time-period that are already in the client price list. You must also specify the maximum number of scheduled prices to be returned in the results.

The ESP should respond with multiple Publish Price commands containing the scheduled prices. Each response is processed by the Price cluster. The obtained price is checked against the prices currently in the price list on the client. If the price is not currently in the list, it is added to the list and an E_SE_PRICE_TABLE_ADD event is generated to indicate that a price has been added.

A pointer must be specified to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which the request is sent
- *u8DestinationEndPointId* Number of the remote endpoint to which the request is sent
- *psDestinationAddress* Pointer to a structure containing the address of the remote node to which the request is sent
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the request
- *u32StartTime* The earliest start-time of any prices to be returned - this is normally set to zero or the current time (UTC)
- *u8NumberOfEvents* The maximum number of scheduled prices to be returned in the results - this should normally be set to: SE_PRICE_NUMBER_OF_CLIENT_PRICE_RECORD_ENTRIES

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_ZBUFFER_FAIL

Parent topic: Functions

eSE_PriceAddPriceEntry

```
teSE__PriceStatus eSE__PriceAddPriceEntry(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    bool_t bOverwritePrevious,
    tsSE_PricePublishPriceCmdPayload *psPricePayload,
    uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used on the Price cluster server to add a price to the local price list. The function also sends an unsolicited Publish Price command containing the new price information to one or more remote endpoints. The function should be called on the ESP when a new price is received from the utility company.

On receiving the Publish Price command, a remote client will automatically add the new price to the local price list. However, you must specify the action to be taken if the time-period of the new price overlaps with the time-period of a price that is already in the client's price list. You can choose to delete the existing price and add the new price, or leave the existing price in place and not add the new price. The rules on overlapping prices are defined in the ZigBee Smart Energy Profile specification.

A pointer must be specified to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which the request is sent
- *u8DestinationEndPointId* Number of the remote endpoint to which the request is sent
- *psDestinationAddress* Pointer to a structure containing the address of the remote node to which the Publish Price command is sent. It is recommended that the command is sent to all bound clients using a ZCL address mode of E_ZCL_AM_BOUND. If the stack has not been started, the E_ZCL_AM_NO_TRANSMIT address mode should be used
- *bOverwritePrevious* Action to be taken if the new price overlaps (in time) a price which is already in the price list:
  - TRUE - existing price deleted, new price added
  - FALSE - new price not added and error returned
- *psPricePayload* Pointer to a structure containing the price information to be added (see Section 40.11.1). This parameter only needs to remain in scope for the duration of this function call
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the command

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE
- E_ZCL_ERR_TIME_NOT_SYNCHRONISED
- E_ZCL_ERR_INSUFFICIENT_SPACE
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_SE_PRICE_OVERFLOW
- E_SE_PRICE_DUPLICATE
- E_SE_PRICE_DATA_OLD

Parent topic: Functions

eSE_PriceAddPriceEntryToClient

```
teSE__PriceStatus eSE__PriceAddPriceEntryToClient(
    uint8 u8SourceEndPointId,
    bool_t bOverwritePrevious,
    tsSE__PricePublishPriceCmdPayload *psPricePayload);
```

Description This function can be used on a Price cluster client to add a price to the local price list directly.

Normally, price entries are automatically added to the price list on a client when a Publish Price command is received from the server (e.g. the ESP). However, this function can be used by the local application to directly add a price entry to the price list on the client. The function should therefore only be used on a device which does not receive price information from the server (but by some other means, such as via the Internet).

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which the request is sent
- *bOverwritePrevious* Action to be taken if the new price overlaps (in time) a price which is already in the price list:
  - TRUE - existing price deleted, new price added
  - FALSE - new price not added and error returned
- *psPricePayload* Pointer to a structure containing the price information to be added (see Section 40.11.1). This parameter only needs to remain in scope for the duration of this function call

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE
- E_ZCL_ERR_TIME_NOT_SYNCHRONISED
- E_ZCL_ERR_INSUFFICIENT_SPACE
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZBUFFER_FAIL
- E_SE_PRICE_OVERFLOW
- E_SE_PRICE_DUPLICATE
- E_SE_PRICE_DATA_OLD

Parent topic: Functions

eSE_PriceGetPriceEntry

```
teSE_PriceStatus eSE_PriceGetPriceEntry(
    uint8 u8SourceEndPointId,
    bool_t bIsServer,
    uint8 u8TableIndex,
    tsSE_PricePublishPriceCmdPayload **psPricePayload);
```

Description This function can be used to obtain the entry with specified index from a price list on the local device. For example, the function can be used on an IPD to obtain a price to display.

You must specify the endpoint on which the local Price cluster resides and whether this cluster instance is a server or a client.

Parameters

- *u8SourceEndPointId* Number of the local endpoint for the price list to be accessed
- *bIsServer* Nature of the Price cluster instance containing the price list:
  - TRUE - server (for example, on ESP)
  - FALSE - client (for example, on IPD)
- *u8TableIndex* The index of the price entry to obtain from the price list (index 0 is the entry with the oldest start-time and may contain the currently active price)
- *psPricePayload* Pointer to a pointer to a structure which will be used to store the obtained price information (see Section 40.11.1), if found. The pointer value that is returned in this parameter points to the structure in the internal storage associated with the list. The data in the structure will be valid as long as the item remains in the list

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_SE_PRICE_TABLE_NOT_FOUND

Parent topic: Functions

eSE_PriceDoesPriceEntryExist

```
teSE_PriceStatus eSE_PriceDoesPriceEntryExist(
    uint8 u8SourceEndPointId,
    bool_t bIsServer,
    uint32 u32StartTime);
```

Description This function can be used to check whether a price entry with the specified start-time is present in a price list on the local device.

You must specify the endpoint on which the local Price cluster resides and whether this cluster instance is a server or a client.

For a price entry to be successfully found, the specified start-time must exactly match the start-time of an entry in the price list, otherwise the status code E_SE_PRICE_NOT_FOUND will be returned.

Parameters

- *u8SourceEndPointId* Number of the local endpoint for the price list to be accessed
- *bIsServer* Nature of the Price cluster instance containing the price list:
  - TRUE - server
  - FALSE - client
- *u32StartTime* Start-time of the price entry to search for

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_SE_PRICE_NOT_FOUND

Parent topic: Functions

eSE_PriceRemovePriceEntry

```
teSE_PriceStatus eSE_PriceRemovePriceEntry(
    uint8 u8SourceEndPointId,
    bool_t bIsServer,
    uint32 u32StartTime);
```

Description This function can be used to delete a price entry with specified start-time from a price list on the local device.

You must specify the endpoint on which the local Price cluster resides and whether this cluster instance is a server or a client.

For the successful deletion of a price entry, the specified start-time must exactly match the start-time of an entry in the price list, otherwise the status code E_SE_PRICE_NOT_FOUND will be returned.

Parameters

- *u8SourceEndPointId* Number of the local endpoint on which Price cluster resides
- *bIsServer* Nature of the Price cluster instance containing the price list:
  - TRUE - server
  - FALSE - client
- *u32StartTime* The start-time of the price entry to delete

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_SE_PRICE_NOT_FOUND
- E_SE_PRICE_TABLE_NOT_FOUND

Parent topic: Functions

eSE_PriceClearAllPriceEntries

```
teSE_PriceStatus eSE_PriceClearAllPriceEntries(
    uint8 u8SourceEndPointId,
    bool_t bIsServer);
```

Description This function can be used to delete all entries in a price list on the local device.

You must specify the endpoint on which the local Price cluster resides and whether this cluster instance is a server or a client.

Parameters

- *u8SourceEndPointId* Number of the local endpoint for the price list to be cleared
- *bIsServer* Nature of the Price cluster instance containing the price list:
  - TRUE - server
  - FALSE - client

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_CLUSTER_NOT_FOUND

Parent topic: Functions

eSE_PriceAddConversionFactorEntry

```
teZCL_Status eSE_PriceAddConversionFactorEntry(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    bool_t bOverwritePrevious,
    tsSE_PricePublishConversionCmdPayload
```

(continues on next page)

(continued from previous page)

```
*psPublishConversionCmdPayload,
uint8 *pu8TransactionSequenceNumber);
```

Description The function can be used on a Price cluster server to add a new conversion factor entry to the internal list of scheduled conversion factors maintained by the cluster. The function also sends an unsolicited Publish Conversion Factor command to the Price cluster client nodes in the network, to advertise the new conversion factor. Therefore, the function should be called on the ESP when a new conversion factor is received from the utility company.

On receiving the Publish Conversion Factor command, a remote client automatically adds the new conversion factor to the local conversion factor list. However, if the new entry has the same start-time as an existing entry in the list, the outcome depends on the setting of the boolean parameter *bOverwritePrevious* in this function:

- If this parameter is set to TRUE then the existing entry is removed and the new entry is added
- If this parameter is set to FALSE then the Issuer Event IDs of the two conversion factor entries are compared:
  - If the Event ID of the new entry is the greater, the existing entry is removed and the new entry is added
  - If the Event ID of the existing entry is the greater, E_ZCL_FAIL is returned and the list is not modified

A pointer must be specified to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which the request is sent
- *u8DestinationEndPointId* Number of the remote endpoint to which the request is sent
- *psDestinationAddress* Pointer to a structure containing the address of the remote node to which the request is sent
- *bOverwritePrevious* Determines whether an existing conversion factor with the same start-time on the clients will be over-written without comparing Event IDs (see above):
  - TRUE - over-write existing entry
  - FALSE - compare Event IDs first
- *psPublishConversionCmdPayload* Pointer to conversion factor entry to be added to list on server and advertised to clients
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the request

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_TIME_NOT_SYNCHRONISED

Parent topic: Functions

eSE_PriceGetConversionFactorSend

```
teZCL_Status eSE_PriceGetConversionFactorSend(
        uint8 u8SourceEndPointId,
        uint8 u8DestinationEndPointId,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        uint32 u32StartTime,
        uint8 u8NumberOfEvents);
```

Description The function can be used on a Price cluster client to send a Get Conversion Factor request to the Price cluster server. Therefore, it is used by a device (such as an IPD) to obtain scheduled conversion factor values from the ESP. The function allows scheduled conversion factors to be obtained with start-times greater than or equal to a specified time, *u32StartTime*.

The ESP should respond with a Publish Conversion Factor command containing up to *u8NumberOfEvent* scheduled conversion factor values. The Price cluster on the receiving client processes the response by updating the local conversion factor list, as follows. For each conversion factor received in the response, the event E_SE_PRICE_CONVERSION_FACTOR_ADD is generated.

A pointer must be specified to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which the request is sent
- *u8DestinationEndPointId* Number of the remote endpoint to which the request is sent
- *psDestinationAddress* Pointer to a structure containing the address of the remote node to which the request is sent
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the request
- *u32StartTime* Earliest start-time of scheduled conversion factors to be returned - a setting of 0 returns the factor that is currently active and factors with start-times in the future
- *u8NumberOfEvents* Maximum number of conversion factors to be returned as a result of this request

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZTRANSMIT_FAIL

Parent topic: Functions

eSE_PriceGetConversionFactorEntry

```
teSE__PriceStatus eSE__PriceGetConversionFactorEntry(
    uint8 u8SourceEndPointId,
    bool_t bIsServer,
    uint8 u8TableIndex,
    sSE__PricePublishConversionCmdPayload
    **ppsPublishConversionCmdPayload);
```

Description This function can be used to obtain the entry with the specified index from the conversion factor list on the local device. For example, the function can be used on an IPD to obtain a conversion factor to display.

You must specify the endpoint on which the local Price cluster resides and whether this cluster instance is a server or a client.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint for the conversion factor list to be accessed
- *bIsServer*: Nature of the Price cluster instance containing the list:
  - TRUE - server (example on ESP)
  - FALSE - client (example on IPD)
- *u8TableIndex*: The index of the entry to obtain from the conversion factor list (index 0 is the entry with the oldest start-time and may contain the currently active conversion factor)
- *ppsPublishConversionCmdPayload*: Pointer to a pointer to a structure which will be used to store the obtained conversion factor information (see Section40.11.2), if found. The pointer value that is returned in this parameter points to the structure in the internal storage associated with the list. The data in the structure will be valid as long as the item remains in the list

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_SE_PRICE_TABLE_NOT_FOUND

Parent topic: Functions

eSE_PriceDoesConversionFactorEntryExist

```
teSE__PriceStatus eSE__PriceDoesConversionFactorEntryExist(
    uint8 u8SourceEndPointId,
    bool_t bIsServer,
    uint32 u32StartTime);
```

Description This function can be used to check whether a conversion factor entry with the specified start-time is present in a conversion factor list on the local device.

You must specify the endpoint on which the local Price cluster resides and whether this cluster instance is a server or a client.

For a conversion factor entry to be successfully found, the specified start-time must exactly match the start-time of an entry in the conversion factor list, otherwise the status code E_SE_PRICE_NOT_FOUND will be returned.

Parameters

- *u8SourceEndPointId* Number of the local endpoint for the conversion factor list to be accessed
- *bIsServer* Nature of the Price cluster instance containing the price list:
- TRUE - server
- FALSE - client
- *u32StartTime* Start-time of the conversion factor entry to search for

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_SE_PRICE_NOT_FOUND

Parent topic: Functions

eSE_PriceRemoveConversionFactorEntry

```
teSE__PriceStatus eSE__PriceRemoveConversionFactorEntry(
    uint8 u8SourceEndPointId,
    bool_t bIsServer,
    uint32 u32StartTime);
```

Description This function can be used to delete a conversion factor entry with specified start-time from conversion factor list on the local device.

You must specify the endpoint on which the local Price cluster resides and whether this cluster instance is a server or a client.

For the successful deletion of a conversion factor entry, the specified start-time must exactly match the start-time of an entry in the conversion factor list, otherwise the status code E_SE_PRICE_NOT_FOUND is returned.

Parameters

- *u8SourceEndPointId* Number of the local endpoint for the conversion factor list to be accessed
- *bIsServer* Nature of the Price cluster instance containing the list:
  - TRUE - server
  - FALSE - client
- *u32StartTime* The start-time of the conversion factor entry to delete

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_SE_PRICE_NOT_FOUND
- E_SE_PRICE_TABLE_NOT_FOUND

Parent topic: Functions

eSE_PriceClearAllConversionFactorEntries

```
teSE_PriceStatus eSE_PriceClearAllConversionFactorEntries(
    uint8 u8SourceEndPointId,
    bool_t bIsServer);
```

Description This function can be used to delete all entries in a conversion factor list on the local device.

You must specify the endpoint on which the local Price cluster resides and whether this cluster instance is a server or a client.

Parameters

- *u8SourceEndPointId* Number of the local endpoint for the conversion factor list to be cleared
- *bIsServer* Nature of the Price cluster instance containing the price list:
- TRUE - server
- FALSE - client

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_CLUSTER_NOT_FOUND

Parent topic: Functions

eSE_PriceAddCalorificValueEntry

```
teZCL_Status eSE_PriceAddCalorificValueEntry(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    bool_t bOverwritePrevious,
    tsSE_PricePublishCalorificValueCmdPayload
    *psPublishCalorificValueCmdPayload,
    uint8 *pu8TransactionSequenceNumber);
```

Description The function can be used on a Price cluster server to add a calorific value entry to the internal list of scheduled calorific values maintained by the cluster. The function also sends an unsolicited Publish Calorific Value command to the Price cluster client nodes in the network, to advertise the new calorific value. Therefore, the function should be called on the ESP when a new calorific value is received from the utility company.

On receiving the Publish Calorific Value command, a remote client automatically adds the new calorific value to the local calorific value list. However, if the new entry has the same start-time as an existing entry in the list, the outcome depends on the setting of the boolean parameter *bOverwritePrevious* in this function:

- If this parameter is set to TRUE then the existing entry is removed and the new entry is added
- If this parameter is set to FALSE then the Issuer Event IDs of the two calorific value entries are compared:
  - If the Event ID of the new entry is the greater, the existing entry is removed and the new entry is added
  - If the Event ID of the existing entry is the greater, E_ZCL_FAIL is returned and the list is not modified

A pointer must be specified to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which the request is sent
- *u8DestinationEndPointId*: Number of the remote endpoint to which the request is sent
- *psDestinationAddress*: Pointer to a structure containing the address of the remote node to which the request is sent
- *bOverwritePrevious*: Determines whether an existing calorific value with the same start-time on the clients will be over-written without comparing Event IDs (see above):
  - TRUE - over-write existing entry
  - FALSE - compare Event IDs first
- *psPublishCalorificValueCmdPayload* Pointer to calorific value entry to be added to list on server and advertised to clients
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the request

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_TIME_NOT_SYNCHRONISED

Parent topic: Functions

eSE_PriceGetCalorificValueSend

```

        uint8 u8SourceEndPointId,
        uint8 u8DestinationEndPointId,
```

(continues on next page)

(continued from previous page)

```
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    uint32 u32StartTime,
    uint8 u8NumberOfEvents);
```

Description The function can be used on a Price cluster client to send a Get Calorific Value request to the Price cluster server. Therefore, it is used by a device (such as an IPD) to obtain scheduled calorific values from the ESP. The function allows scheduled calorific values to be obtained with start-times greater than or equal to a specified time, *u32StartTime*.

The ESP should respond with a Publish Calorific Value command containing up to *u8NumberOfEvent* scheduled calorific values. The Price cluster on the receiving client processes the response by updating the local calorific value list, as follows. For each calorific value received in the response, the event E_SE_PRICE_CALORIFIC_VALUE_ADD is generated.

A pointer must be specified to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which the request is sent
- *u8DestinationEndPointId*: Number of the remote endpoint to which the request is sent
- *psDestinationAddress*: Pointer to a structure containing the address of the remote node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to store the Transaction Sequence Number (TSN) of the request
- *u32StartTime*: Earliest start-time of scheduled calorific values to be returned - a setting of 0 returns the value that is currently active and values with start-times in the future
- *u8NumberOfEvents*: Maximum number of calorific values to be returned as a result of this request

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_ZBUFFER_FAIL
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_ZTRANSMIT_FAIL

Parent topic:*Price Cluster*

Return codes In addition to some of the ZCL status enumerations, the following enumerations are returned by Price cluster functions (see Section 40.9) to indicate the outcome of the function call.

```
typedef enum PACK
{
    E_SE_PRICE_OVERLAP =0x80,
    E_SE_PRICE_TABLE_NOT_YET_ACTIVE,
    E_SE_PRICE_DATA_OLD,
    E_SE_PRICE_NOT_FOUND,
    E_SE_PRICE_TABLE_NOT_FOUND,
    E_SE_PRICE_OVERFLOW,
    E_SE_PRICE_DUPLICATE,
    E_SE_PRICE_NO_TABLES,
    E_SE_PRICE_BLOCK_PERIOD_TABLE_NOT_YET_ACTIVE,
    E_SE_PRICE_NO_BLOCKS,
```

(continues on next page)

(continued from previous page)

```
    E_SE_PRICE_NUMBER_OF_BLOCK_THRESHOLD_MISMATCH,
    E_SE_BLOCK_PERIOD_OVERFLOW,
    E_SE_BLOCK_PERIOD_DUPLICATE,
    E_SE_BLOCK_PERIOD_DATA_OLD,
    E_SE_BLOCK_PERIOD_OVERLAP,
    E_SE_PRICE_STATUS_ENUM_END
} teSE_PriceStatus;
```

The above enumerations are described in the table below.

Enumeration	Description
E_SE_PRICE_OVERLAP	New price overlaps (in time) with existing price in price list
E_SE_PRICE_TABLE_NOT_	No active price at head of price list
E_SE_PRICE_DATA_OLD	Attempt made to add price which overlaps (in time) with existing price in price list and which is older than existing price *
E_SE_PRICE_NOT_FOUND	Specified price was not found in price list
E_SE_PRICE_TABLE_NOT_	Specified price list was not found
E_SE_PRICE_OVERFLOW	Attempt to add price to price list failed because end-time for new price (start-time + duration x 60) exceeds maximum permissible time value of 0xFFFFFFFF (UTC)
E_SE_PRICE_DUPLICATE	Specified price information already exists in price list
E_SE_PRICE_NO_TABLES	Reserved for future use (for Block mode)
E_SE_PRICE_BLOCK_PERI BLE_NOT_YET_ACTIVE	Reserved for future use (for Block mode)
E_SE_PRICE_NO_BLOCKS	Reserved for future use (for Block mode)
E_SE_PRICE_NUMBER_OF	Reserved for future use (for Block mode)
E_SE_BLOCK_PERIOD_OV	Reserved for future use (for Block mode)
E_SE_BLOCK_PERIOD_DU	Reserved for future use (for Block mode)
E_SE_BLOCK_PERIOD_DA	Reserved for future use (for Block mode)
E_SE_BLOCK_PERIOD_OV	Reserved for future use (for Block mode)

* Value of u32IssuerEventId in tsSE_PricePublishPriceCmdPayload structure (see Section 40.11.1) is less for the price to be added than for the existing (overlapping) price.

Parent topic:*Price Cluster*

Structures

tsSE_PricePublishPriceCmdPayload This structure is used to hold price information to be added to a price list of a Price cluster:

```
typedef struct {
    uint8           u8UnitOfMeasure;
    uint8           u8PriceTrailingDigitAndPriceTier;
    uint8           u8NumberOfPriceTiersAndRegisterTiers;
    uint8           u8PriceRatio;
    uint8           u8GenerationPriceRatio;
    uint8           u8AlternateCostUnit;
    uint8           u8AlternateCostTrailingDigit;
    uint8           u8NumberOfBlockThresholds;
    uint8           u8PriceControl;
    uint16          u16Currency;
    uint16          u16DurationInMinutes;
    uint32          u32ProviderId;
```

(continues on next page)

(continued from previous page)

```
    uint32              u32IssuerEventId;
    uint32              u32StartTime;
    uint32              u32Price;
    uint32              u32GenerationPrice;
    uint32              u32AlternateCostDelivered;
    tsZCL_OctetString   sRateLabel;
} tsSE_PricePublishPriceCmdPayload;
```

where:

- u8UnitOfMeasure indicates the resource (e.g. electricity) and unit of measure (e.g. kWh) for the pricing (see Section 42.10.3)
- u8PriceTrailingDigitAndPriceTier is an 8-bit bitmap indicating the price tier and the number of digits after the decimal point in the price:
  - The 4 most significant bits give the number of digits to the right of the decimal point in the price
  - The 4 least significant bits give the price tier in the range 1 to 6
- u8NumberOfPriceTiersAndRegisterTiers is an 8-bit bitmap indicating the number of price tiers available and the particular tier that the price information in the structure relates to:
  - The 4 most significant bits give the number of available price tiers in the range 0 to 6
  - The 4 least significant bits give the price tier used in the range 1 to 6

    (this value must be less than or equal to the value in the 4 leading bits)
- u8PriceRatio (optional) is the ratio of the price quoted in u32Price to the 'normal' price offered by the utility company. The actual price ratio should be multiplied by 10 for encoding this field, so that a field value of 0x01 represents 0.1 and 0xFE represents 25.4, while 0xFF indicates that the field is not used
- u8GenerationPriceRatio (optional) is the ratio of the price quoted in u32GenerationPrice to the 'normal' price offered by the utility company. The actual price ratio should be multiplied by 10 for encoding this field, so that a field value of 0x01 represents 0.1 and 0xFE represents 25.4, while 0xFF is reserved to indicate that the field is not used
- u8AlternateCostUnit (optional) is an 8-bit bitmap indicating the unit for the alternative cost in u32AlternateCostDelivered. Currently, the only supported unit is kilograms of CO2, indicated by the value 0x01
- u8AlternateCostTrailingDigit (optional) is an 8-bit bitmap in which the 4 most significant bits indicate the number of digits after the decimal point in u32AlternateCostDelivered (the 4 least significant bits are reserved)
- u8NumberOfBlockThresholds is reserved for future use (for Block mode)
- u8PriceControl is reserved for future use (for Block mode)
- u16Currency indicates the currency (e.g. Euro) used for the price - this field should be set to the appropriate value defined by ISO 4217
- u16DurationInMinutes indicates the duration, in minutes, for which the price will be valid (0xFFFF indicates that price will remain valid until changed)
- u32ProviderId is an identifier for the utility company
- u``32IssuerEventId is a unique identifier for the price information - the higher its value, the more recently the price information was issued (a UTC time-stamp could be used in this field)
- u``32StartTime indicates the start-time (UTC) for the price, in seconds. The special value 0x00000000 denotes a start-time of 'now'

- u``32Price is the resource price per unit indicated in u8UnitOfMeasure, expressed in the currency indicated in u16Currency, with the position of the decimal point as indicated in u8PriceTrailingDigitAndPriceTie``r
- u``32GenerationPrice (optional) is the resource price per unit indicated in u8UnitOfMeasure, expressed in the currency indicated in u16Currency and with the position of the decimal point as indicated in u8PriceTrailingDigitAndPriceTier, for a resource that is generated on the customer premises and supplied to the utility company (e.g. solar-sourced electric power supplied to the national grid). A value of 0xFFFFFFFF indicates that this field is not used
- u32AlternateCostDelivered (optional) indicates an alternative cost (per resource consumption unit) which is measured by a means other than monetary - for example, the amount of CO2 emitted per unit of gas consumed This alternative cost is interpreted as specified by u8AlternateCostUnit and u8AlternateCostTrailingDigit
- sRateLabel is a string of up to 12 characters containing a label for the price information in the structure

Parent topic: Structures

tsSE_PricePublishConversionCmdPayload This structure is used to hold information to be added to a conversion factor list of a Price cluster:

```
typedef struct {
    uint32          u32IssuerEventId;
    uint32          u32StartTime;
    uint32          u32ConversionFactor;
    zbmap8           u8ConversionFactorTrailingDigit;
}tsSE_PricePublishConversionCmdPayload;
```

where:

- u32IssuerEventId is a unique identifier for the conversion factor information - the higher the value, the more recently the information was issued
- u32StartTime is the start-time of the conversion factor value. This is the time at which the conversion factor value is scheduled to become active
- u32ConversionFactor is used only for gas and accounts for the variation in the volume of gas with temperature and pressure (the value is dimensionless)
- u8ConversionFactorTrailingDigit is an 8-bit bitmap which indicates the location of the decimal point in the u32ConversionFactor field. The most significant 4 bits indicate the number of digits after the decimal point. The remaining bits are reserved

Parent topic: Structures

tsSE_PricePublishCalorificValueCmdPayload This structure is used to hold information to be added to a calorific value list of the Price cluster:

```
typedef struct {
    zenum8              u8CalorificValueUnit;
    zbmap8              u8CalorificValueTrailingDigit;
    uint32             u32IssuerEventId;
    uint32             u32StartTime;
    uint32             u32CalorificValue;
}tsSE_PricePublishCalorificValueCmdPayload;
```

where:

- u8CalorificValueUnit is an 8-bit enumerated value which defines the unit for the u32CalorificValue field (below). It indicates whether the calorific value is quantified per unit volume or per unit mass - see Section 40.12.3.
- u8CalorificValueTrailingDigit is an 8-bit bitmap which indicates the location of the decimal point in the u32CalorificValue field (below). The most significant 4 bits indicate the number of digits after the decimal point. The remaining bits are reserved
- u32IssuerEventId is a unique identifier for the calorific value information - the higher the value, the more recently the information was issued
- u32StartTime is the start-time of the calorific value. This is the time at which the conversion factor value is scheduled to become active
- u32CalorificValue is used only for gas and indicates the quantity of energy in MJ that is generated per unit volume or unit mass of gas burned (see u8CalorificValueUnit). The position of the decimal point is indicated by u8CalorificValueTrailingDigit described above

Parent topic:*Price Cluster*

Enumerations

'Attribute ID' Enumerations The following structure contains the enumerations used to identify the attributes of the Price cluster.

Note: Only the Tier Label attributes are currently used. The remaining attributes are reserved for future use (for Block mode).

```
typedef enum PACK
{
/*Price Cluster Attribute Tier Price Label Set Attr Ids (D.4.2.2.1)*/
   E_CLD_P_ATTR_TIER_1_PRICE_LABEL = 0x0000,
   E_CLD_P_ATTR_TIER_2_PRICE_LABEL,
   ...
   ...
   E_CLD_P_ATTR_TIER_15_PRICE_LABEL,
/*Price Cluster Attribute Block Threshold Set Attr IDs (D.4.2.2.2)*/
   E_CLD_P_ATTR_BLOCK1_THRESHOLD = 0x0100,
   E_CLD_P_ATTR_BLOCK2_THRESHOLD,
   ...
   ...

    E_SE_PRICE_CONVERSION_FACTOR_TABLE_ACTIVE,
    E_SE_PRICE_CONVERSION_FACTOR_ADD,
    E_SE_PRICE_CALORIFIC_VALUE_TABLE_ACTIVE,
    E_SE_PRICE_CALORIFIC_VALUE_ADD,
    E_SE_PRICE_CBET_ENUM_END
} teSE_PriceCallBackEventType;
```

The above event types are described in *Table 56* below.

Note: For further details on Price events, refer to Section 40.8.

Event Type Enumeration	Description
E_SE_PRICE_TABLE_ADD	Generated when a new scheduled price is added to the local price list
E_SE_PRICE_TABLE_ACTIVE	Generated when a new price becomes active or the active price expires
E_SE_PRICE_GET_CURRENT_I	Generated on the server when a Get Current Price command is received from a client
E_SE_PRICE_TIME_UPDATE	Generated on a client when a Publish Price command is received from the server
E_SE_PRICE_ACK_RECEIVED	Generated on a server when a Price Acknowledgment command is received from a client
E_SE_PRICE_NO_PRICE_TABL	Generated when an active price expires, is deleted from the price list and the list becomes empty
E_SE_PRICE_READ_BLOCK_PI	Reserved for future use (for Block mode)
E_SE_PRICE_BLOCK_PERIOD_	Reserved for future use (for Block mode)
E_SE_PRICE_NO_BLOCK_PERI	Reserved for future use (for Block mode)
E_SE_PRICE_BLOCK_PERIOD_	Reserved for future use (for Block mode)
E_SE_PRICE_READ_BLOCK_TI	Reserved for future use (for Block mode)
E_SE_PRICE_CONVERSION_FA	Generated when a new conversion factor value becomes active
E_SE_PRICE_CONVERSION_FA	Generated when a new conversion factor entry is advertised by the ESP via a Publish Conversion Factor command
E_SE_PRICE_CALORIFIC_VALI	Generated when a new calorific value becomes active
E_SE_PRICE_CALORIFIC_VALI	Generated when a new calorific value entry is advertised via a Publish Calorific Value command

Parent topic: Enumerations

'Calorific Value Unit' Enumerations The possible units for the calorific value attribute of the Price cluster are enumerated in the tsSE_PriceCalorificValueUnits structure below:

```
typedef enum PACK
{
    E_SE_MEGA_JOULES_METER_CUBE  = 0x01,
    E_SE_MEGA_JOULES_KILOGRAM = 0x02
```

(continues on next page)

(continued from previous page)

```
} tsSE__PriceCalorificValueUnits;
```

The above enumerations are described in *Table 57* below.

Enumeration	Description
E_SE_MEGA_JOULES_METER_CUBE	Calorific value measured in MJ/m3
E_SE_MEGA_JOULES_KILOGRAM	Calorific value measured in MJ/kg

Parent topic: Enumerations

Parent topic:*Price Cluster*

Compile-time options This section describes the compile-time options that may be enabled in the **zcl_options.h** file of an application that uses the Price cluster.

The Price cluster is enabled by defining CLD_PRICE.

Client and server versions of the cluster are defined by PRICE_CLIENT and PRICE_SERVER, respectively.

Price List Size The maximum number of prices that can be stored in the price list on a server and client defaults to five and two respectively. These default values can be over-ridden by assigning values to the corresponding macro below:

- SE_PRICE_NUMBER_OF_SERVER_PRICE_RECORD_ENTRIES
- SE_PRICE_NUMBER_OF_CLIENT_PRICE_RECORD_ENTRIES

Price Tier Label Attribute Set The maximum number of supported Price Tier Label Attribute Sets can be defined by assigning a value between 1 and 15 (inclusive) to CLD_P_ATTR_TIER_PRICE_LABEL_MAX_COUNT.

Block Threshold Attribute Set The maximum number of supported Block Threshold Attribute Sets can be defined by assigning a value between 1 to 15 (inclusive) to CLD_P_ATTR_BLOCK_THRESHOLD_MAX_COUNT.

Block Price Information Attribute Set The maximum number of supported Block Price Information Attribute Sets can be defined by assigning a value (the maximum of which is shown below in brackets) to each of the following:

- CLD_P_ATTR_NO_TIER_BLOCK_PRICES_MAX_COUNT (16)
- CLD_P_ATTR_NUM_OF_TIERS_PRICE (15)
- CLD_P_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_PRICE (16)

Conversion Factor (Gas Only) Conversion factor in the Price cluster is enabled by defining the macro PRICE_CONVERSION_FACTOR.

The attributes for conversion factor are enabled by defining the following macros:

- CLD_P_ATTR_CONVERSION_FACTOR
- CLD_P_ATTR_CONVERSION_FACTOR_TRAILING_DIGIT

The default value of the maximum number of entries that can be stored in the conversion factor list which is maintained on the Price cluster server and client is 2. This value can be over-ridden by assigning another value to the macro:

SE_PRICE_NUMBER_OF_CONVERSION_FACTOR_ENTRIES

Calorific Value (Gas Only) Calorific value in the Price cluster is enabled by defining the macro PRICE_CALORIFIC_VALUE.

The attributes for calorific value are enabled by defining the following macros:

- CLD_P_ATTR_CALORIFIC_VALUE
- CLD_P_ATTR_CALORIFIC_VALUE_UNIT
- CLD_P_ATTR_CALORIFIC_VALUE_TRAILING_DIGIT

The default value of the maximum number of entries that can be stored in the calorific value list which is maintained on the server and client is 2. This value can be over-ridden by assigning another value to the macro:

SE_PRICE_NUMBER_OF_CALORIFIC_VALUE_ENTRIES

Parent topic:*Price Cluster*

Demand-Response and Load Control Cluster This chapter outlines the Demand-Response and Load Control (DRLC) cluster. The cluster is able to receive load control requests from the utility company and act upon them by controlling an attached appliance, such as a heater or pump - this is the 'demand-response' functionality.

The DRLC cluster has a Cluster ID of 0x0701.

Overview The DRLC cluster is required in ZigBee devices as indicated in the table below.

	Server-side	Client-side
Mandatory in...	ESP Load Control Device	PCT
Optional in...		IPD
	Smart Appliance	

The ESP acts as the DRLC cluster server, since it is the device which receives Load Control Events (LCEs) from the utility company via the backhaul network. Other devices act as clients and receive the LCEs forwarded by the ESP:

- An IPD would normally display a list of LCEs to allow the consumer to manually modify consumption.
- A Load Control Device, PCT or Smart Appliance would participate in an LCE by automatically adjusting the consumption of the device.

Devices that participate in an LCE must report their participation back to the ESP. Participation may result in the consumer receiving a credit on their utility bill.

Note: In the current NXP implementation, the DRLC cluster client is contained within an IPD only. This illustrates how to incorporate the DRLC cluster in other devices which need to participate in LCEs.

The LCEs contain a time-stamp. Therefore, devices which support the DRLC cluster client and which participate in LCEs must implement the Time cluster and maintain a real-time clock.

The DRLC cluster is enabled by defining CLD_DRLC in the **zcl_options.h** file. Further compile-time options for the DRLC cluster are detailed in Section 41.12.

Parent topic:*Demand-Response and Load Control Cluster*

DRLC Cluster structure and attributes The DRLC cluster has no server attributes but has client attributes that are contained in the following tsCLD_DRLC structure:

```
typedef struct
{
    uint8               u8UtilityEnrolmentGroup;
    uint8               u8StartRandomizeMinutes;
    uint8               u8StopRandomizeMinutes;
    uint16              u16DeviceClassValue;
} tsCLD_DRLC;
```

where:

- u8UtilityEnrolmentGroup identifies the 'enrolment' group to which the device belongs, where a group of devices is defined by the utility company in order to aid load management in a large system. The default value of 0x00 is used to indicate membership of all groups.
- u8StartRandomizeMinutes specifies the largest random delay, in minutes, that can be applied to the start of a Load Control Event (so a random delay, no greater than this value, will be applied to an individual event). The valid range of values is 0x00 to 0x3C (0 to 60 mins), where 0x00 indicates that no delay is to be applied.
- u8StopRandomizeMinutes specifies the largest random delay, in minutes, that can be applied to the end of a Load Control Event (so a random delay, no greater than this value, will be applied to an individual event). The valid range of values is 0x00 to 0x3C, where 0x00 indicates that no delay is to be applied.
- u16DeviceClassValue is a bitmap specifying the relevant device classes (for example, water heater and pool pump). Enumerations are provided for the device classes and are detailed in Section 41.10.1. If more than one device class is required, the relevant enumerations can be bitwise-ORed.

Note: It may be desirable to refuse write access to the u16DeviceClassValue attribute on a device. To do this, when a 'write attributes' request is received and an E_ZCL_CBET_CHECK_ATTRIBUTE_RANGE event is generated for this attribute, the application should set the eAttributeStatus field of the event to E_ZCL_DENY_ATTRIBUTE_ACCESS.

Parent topic:*Demand-Response and Load Control Cluster*

Initialization Provided that the DRLC cluster is enabled in the compile-time options (see Section41.12), the cluster is automatically initialized when the ZCL is initialized and the ZigBee device is registered in the application - that is, by calling **eZCL_Initialise()** and the relevant endpoint registration function for the device, for example:

- **eSE_RegisterEspEndPoint()** on a standalone ESP (cluster server)
- **eSE_RegisterIPDEndPoint()** on an IPD (cluster client)

As part of this initialization, the DRLC cluster is created and, on the ESP, a DRLC timer server is registered to support time-stamps in the LCEs.

A DRLC cluster client must also perform a number of other initialization steps in order to establish communication with the cluster server. These are described below.

1. **Set 'device class' attribute:** The value of the 'device class' attribute (see Section 41.2) must be set immediately after **eSE_RegisterIPDEndPoint()** is called and before the network is started.
2. **Bind to server:** A non-sleeping client should bind its endpoint to the server using the ZigBee PRO API function **ZPS_eAplZdpBindUnbindRequest()**. This allows the server to send out unsolicited LCEs to the client.

- Before this binding can take place, the client must obtain the IEEE/MAC address of the ESP/server. This can be achieved by first using the function **ZPS_eAplZdpMatchDescRequest()** to find the ESP/Server and to obtain its network address. The function **ZPS_eAplZdpIeeeAddrRequest()** can then be used to obtain the corresponding IEEE/MAC address. Once found, both addresses must be added to the local Address Map using the function **ZPS_eAplZdoAddAddrMapEntry()**.
- All four of the above ZPS functions are described in the *ZigBee 3.0 Stack User Guide (JNUG3130)*.

3. **Synchronize time with ESP:** A client should synchronize ZCL time with the ESP using the Time cluster as soon as initialization is complete. It is not possible to process unsolicited LCEs with a 'start-time of now' until ZCL time has been synchronized.

Once the clients have been set up, the ESP/server may need to configure the enrolment groups and randomization attributes of the DRLC clients (see Section41.2). The ESP may use one of the following mechanisms to determine when a DRLC client has come on-line:

- A Get Scheduled Events message is received from a new client
- A Report Event Status message is received from a new client
- A binding request is received from a new client

Parent topic:*Demand-Response and Load Control Cluster*

Load Control Events (LCEs) The Load Control Event (LCE) is an instruction, which originates from the utility company, to schedule a temporary adjustment of consumption in devices that support the DRLC cluster. The contents of an LCE are outlined in Section 41.4.1.

An LCE is sent from the utility company to the DRLC server (ESP) of a ZigBee network, from where it is passed to DRLC clients. The LCEs are held in lists on the server and clients, as described in Section 41.4.2.

LCE handling is described in Section 41.5.

LCE Contents The information contained in an LCE includes:

- LCE ID (provided by utility company)
- Target device class and enrolment group
- Start-time
- Duration
- Criticality level
- Required adjustment(s)
- Randomization requirements (for start-time and end-time)

For a full list and description of the LCE data, refer to the description of the LCE structure tsSE_DRLCLoadControlEvent in Section 41.11.1.

Parent topic: Load Control Events (LCEs)

LCE Lists The DRLC cluster server and clients each hold the following lists of LCEs:

- **Active list:** Contains LCEs that are currently being executed - it is possible for more than one LCE to be active at the same time, provided that their device classes and enrolment groups do not clash.
- **Scheduled list:** Contains LCEs that are due to be executed in the future - that is, their start-time is later than the current time.
- **Cancelled list:** Contains LCEs that have been canceled with a randomized end-time and whose random end-time has not yet been reached.
- **Deallocated list:** Contains expired LCEs and therefore a record of the free storage for LCEs - used internally by the cluster (and not by the application).

A new LCE is first added to the Scheduled list, unless it has a 'start-time of now' in which case it is added to the Active list. An LCE in the Scheduled list is automatically moved to the Active list at the scheduled start-time (or at the randomized start-time). At the end of an active LCE, it is automatically moved to the Deallocated list. However, an active LCE which is canceled with a randomised end-time is automatically moved to the Cancelled list, where it stays until the end-time has been reached (when it is moved to the Deallocated list).

The addition of a new LCE on the cluster server is performed by the server application, as described in Section 41.5.1, but is done automatically by the cluster on the clients. All other operations on LCE lists, apart from cancelation (see Section 41.5.3), are performed automatically by the cluster on both server and client.

Functions are provided to access entries in the local LCE lists:

- **eSE_DRLCGetLoadControlEvent()** can be used to obtain a particular LCE entry (with specified list index) in any one of the local lists
- **eSE_DRLCFindLoadControlEvent()** can be used to search for and obtain a particular LCE (with specified ID) in any of the local lists

Parent topic: Load Control Events (LCEs)

Parent topic:*Demand-Response and Load Control Cluster*

LCE Handling LCEs are handled on the DRLC cluster server and clients as described in Section41.5.1 and Section 41.5.2 respectively. Canceling LCEs is described in Section41.5.3.

Note: The DRLC callback events referred to in this section are further described in Section 41.7 and are handled by the callback function that is registered as part of the device endpoint registration.

LCE Handling on Server When a new LCE is received from the utility company, it is the responsibility of the application on the ESP (DRLC cluster server) to add this LCE to the local 'Scheduled' list (or to the 'Active' list, if the LCE has a 'start-time of now'). This addition is performed using the function **eSE_DRLCAddLoadControlEvent()**, which also sends the LCE (unsolicited) to the cluster clients. The LCE should normally be sent to all client endpoints with which the cluster server has been bound (see Section 41.3).

Note:

1. **Note 1:**Following the initial reception of LCEs from the utility company, the addition of these LCEs to the list(s) through **eSE_DRLCAddLoadControlEvent()**can be done after calling **eSE_RegisterEspMeterEndPoint()** or **eSE_RegisterEspEndPoint()** but before calling **ZPS_eAplZdoStartStack()**.
2. **Note 2:** On receiving an LCE, the client checks the device class and enrollment group specified within the LCE, and only accepts the LCE if these values match the corresponding DRLC cluster attributes held locally (see Section 41.2).

The cluster server also automatically responds to Get Scheduled Events messages from cluster clients that need current and future LCEs (see Section 41.5.2.2).

Parent topic:LCE Handling

LCE Handling on Clients The sub-sections below describe the various LCE handling activities that take place on a DRLC cluster client.

LCE Activation and De-activation On receiving a new LCE from the DRLC cluster server, a cluster client first checks the device class and enrollment group specified within the LCE. If they do not match those of the local device (see DRLC attributes in Section 41.2), the LCE is discarded.

Note: A DRLC cluster client can opt out of an individual LCE using the **eSE_DRLCSetEventUserOption()** function.

Generally, a valid LCE received from the cluster server is automatically added to the 'Scheduled' list on the client - the E_SE_DRLC_EVENT_COMMAND callback event containing the command SE_DRLC_LOAD_CONTROL_EVENT is generated on the client to indicate that this has been done. However, if the LCE has a 'start-time of now', it is added directly to the 'Active' list, provided that the start-time is not randomized (see below).

If a new LCE is successfully added to the Scheduled (or Active) list, the client sends a Report Event Status message to the server to confirm acceptance of the LCE.

When the start-time of an LCE in the 'Scheduled' list is reached, the LCE is automatically moved to the 'Active' list. The E_SE_DRLC_EVENT_ACTIVE callback event is generated on the client to indicate that this has been done, allowing the application to make the required load adjustment. However, if a randomized start-time is enabled (in the LCE), the move to the 'Active' list is delayed by a random time interval that is no greater than the maximum defined by the cluster attribute u8StartRandomizeMinutes (see Section 41.2).

When the duration of the active LCE has expired, the LCE is automatically moved to the 'De-allocated' list - the E_SE_DRLC_EVENT_EXPIRED callback event is generated on the client to indicate that this has been done, allowing the application to restore the load to the previous level. However, if a randomized end-time is enabled (in the LCE), the move to the 'Deallocated' list is delayed by a random time interval that is no greater than the maximum defined by the cluster attribute u8StopRandomizeMinutes (see Section 41.2).

Note: The above randomize attributes of the DRLC cluster also allow LCE start-time and end-time randomization to be disabled for all LCEs on the local device. If this is the case, randomization settings within the LCE itself are ignored.

Parent topic:LCE Handling on Clients

Getting Scheduled Events The application on the DRLC cluster client can send a Get Scheduled Events message to the cluster server in order to obtain relevant current and future LCEs. This message may be used in the following situations:

- On a non-sleeping device, the application may send this message:
  - immediately after binding with the cluster server in order to get the initial LCEs (subsequent LCEs are received unsolicited from the server).
  - at other times in order to top up its LCE list, if it has previously discarded an LCE due to lack of storage.
- On a sleeping device (End Device), the application may send this message on waking from sleep in order to obtain new LCEs that were distributed by the cluster server during sleep (and therefore not received).

The Get Scheduled Events message can be sent from a client using the function eSE_DRLCGetScheduledEventsSend(). The message includes the earliest start-time of the LCEs of interest, where zero is used to indicate all LCEs - for a sleeping End Device, this time should be set to zero or the current time, in case there are replacements on the server for LCEs already in the client's lists. The message also allows the maximum number of returned LCEs to be specified, where zero is used to indicate all LCEs.

Note: The arrival of the Get Scheduled Events message results in the generation of the E_SE_DRLC_EVENT_COMMAND callback event, containing a DRLC_GET_SCHEDULED_EVENTS command on the cluster server. However, the cluster responds to the message automatically.

On receiving the requested LCEs from the cluster server, the cluster client automatically updates the local LCE lists with the reported LCEs.

Parent topic:LCE Handling on Clients

Reporting LCE Actions to Server By default, a DRLC cluster client sends a Report Event Status message to the cluster server when an LCE is actioned on the client - that is, when an LCE is moved between lists on the client, such as from 'Scheduled' to 'Active' or from 'Active' to 'Deallocated' (see Section 41.4.2). Details of the actioned LCE are sent in a tsSE_DRLCReportEvent structure (see Section 41.11.4). The nature of the action is indicated in this structure using an enumeration (see Section 41.10.8).

Note: The DRLC cluster server is informed of the arrival of a Report Event Status message via the callback event **E_SE_DRLC_EVENT_COMMAND**, containing a SE_DRLC_REPORT_EVENT_STATUS command. The ESP/server may inform the utility company of the reported status - if the message cannot be forwarded immediately then it must be buffered by the application.

If a DRLC cluster client opts out of a particular LCE using the function **eSE_DRLCSetEventUserOption()**, a Report Event Status message is sent to the cluster server to indicate this. On reaching the end-time of the LCE, another Report Event Status message is sent to the server to confirm that the LCE has completed without the participation of the local client.

Parent topic:LCE Handling on Clients

Over-riding LCE Settings The client application can over-ride certain aspects of an LCE using the function **eSE_DRLCSetEventUserData()**, which allows load control data values to be modified, including:

- Criticality level
- Cooling temperature set-point
- Heating temperature set-point
- Load adjustment percentage
- Duty cycle

For example, the ESP/server may request an HVAC device to set its cooling level to 24oC, but the user may choose to over-ride this with a cooling level of 20oC. The above data values and their formats are detailed in the LCE structure description in Section 41.11.1.

The function **eSE_DRLCSetEventUserData()** modifies one load control data value on each call. Therefore, in order to modify more than one data value, the function must be called multiple times.

When a change is made, the cluster client automatically notifies the cluster server by sending a Report Event Status message containing the change.

Parent topic:LCE Handling on Clients

Parent topic:LCE Handling

Canceling LCEs An LCE can be canceled, in which case it is moved to the 'Deallocated' list (possibly via the 'Cancelled' list - see below). A cancellation can only be performed from the DRLC cluster server and is normally sent to all client endpoints that have been bound to the server. Two functions are provided which can be called on the cluster server to perform LCE cancelations:

- **eSE_DRLCCancelLoadControlEvent()** is used to cancel a particular LCE
- **eSE_DRLCCancelAllLoadControlEvents()** is used to cancel all LCEs

Cancellation involves removing the LCE(s) from the 'Scheduled' or 'Active' lists on the cluster server and clients, which is done automatically by the cluster. As a result, the callback event E_SE_DRLC_EVENT_COMMAND is generated, containing a LOAD_CONTROL_EVENT_CANCEL or LOAD_CONTROL_EVENT_CANCEL_ALL command, as appropriate. This indicates whether the cancellation with immediate effect or a random delay is applied:

- If the cancellation is with immediate effect, the application should stop load control for the relevant device(s).
- If a random delay is to be applied to the cancellation, the cluster puts the LCE in the 'Cancelled' list until the delay has expired, when the LCE is moved to the 'Deallocated' list. Another E_SE_DRLC_EVENT_COMMAND callback event containing the command LOAD_CONTROL_EVENT_CANCEL or LOAD_CONTROL_EVENT_CANCEL_ALL is then generated, this time indicating immediate cancellation. The application should now stop load control for the relevant device(s).

Parent topic:LCE Handling

Parent topic:*Demand-Response and Load Control Cluster*

Message Signing (Security) As a security measure, Report Event Status messages can be signed by the DRLC cluster client for non-repudiation purposes (to provide the utility company with evidence that the cluster client sent the message). On the DRLC cluster client, the process involves generating a hash value which is based on the content of the message, then using this value in combination with a device's private key to generate a signature, which is then appended to the message to be sent to the ESP.

Upon message reception on the ESP, the hash value is recalculated based on the received message and then used in conjunction with the public key of the message originator (derived from the originator's certificate) to check the appended signature. To facilitate this checking, the ESP must store the certificates of any nodes that send Report Event Status messages which require verification.

Note:

1. It is recommended that signatures are supported by applications for backward compatibility.
2. Signature fields are included in the Report Event Status structure, detailed in Section 41.11.4.

Message signing must be enabled at compile-time, as described in Section 41.12.

Parent topic:*Demand-Response and Load Control Cluster*

DRLC Events The DRLC cluster has its own events that are handled through the callback mechanism described in *Chapter 3*. If a device uses the DRLC cluster then DRLC event handling must be included in the callback function for the associated endpoint - for example:

- For an ESP (cluster server), this callback function is registered through **eSE_RegisterEspMeterEndPoint()** or **eSE_RegisterEspEndPoint()**
- For an IPD (cluster client), this callback function is registered through **eSE_RegisterIPDEndPoint()**

The relevant callback function is then invoked when a DRLC event occurs.

For a DRLC event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to a tsSE_DRLCCallBackMessage structure which contains the DRLC parameters:

```
typedef struct
{
 teSE_DRLCCallBackEventType  eEventType;
  uint8   u8CommandId;
  teSE_DRLCStatus  eDRLCStatus;
  uint32  u32CurrentTime;
  union {
  tsSE_DRLCLoadControlEvent      sLoadControlEvent;
  tsSE_DRLCCancelLoadControlEvent  sCancelLoadControlEvent;
  tsSE_DRLCCancelLoadControlAllEvent  sCancelLoadControlAllEvent;
  tsSE_DRLCReportEvent       sReportEvent;
  tsSE_DRLCGetScheduledEvents   sGetScheduledEvents;
   } uMessage;
} tsSE_DRLCCallBackMessage;
```

Information on the elements of the above structure is provided in the sub-sections below.

Event and Command Types The eEventType field of the tsSE_DRLCCallBackMessage structure above specifies the type of DRLC event that has been generated - these event types are enumerated in the teSE_DRLCCallBackEventType structure, described below.

Note: The u8CommandId field of the tsSE_DRLCCallBackMessage structure is only required for a DRLC event of type E_SE_DRLC_EVENT_COMMAND (see below).

```
typedef enum PACK
{
   E_SE_DRLC_EVENT_API =0x00,
   E_SE_DRLC_EVENT_COMMAND,
   E_SE_DRLC_EVENT_ACTIVE,
   E_SE_DRLC_EVENT_EXPIRED,
   E_SE_DRLC_EVENT_CANCELLED,
   E_SE_DRLC_EVENT_ENUM_END,
} teSE_DRLCCallBackEventType;
```

E_SE_DRLC_EVENT_API The E_SE_DRLC_EVENT_API event is reserved for internal use.

E_SE_DRLC_EVENT_COMMAND The E_SE_DRLC_EVENT_COMMAND event is generated when a command has been received on either the server or client. In the tsSE_DRLCCallBackMessage structure, the u8CommandId field is used to indicate the corresponding command - one of:

Command	Description
SE_DRLC_LOAD_C(	Generated on a client when a new LCE has been received from the server and added to the 'Scheduled' (or 'Active') list - the LCE is included in the

uMessage.LoadControlEvent field of the tsSE_DRLCCallBackMessage structure

| |SE_DRLC_LOAD_CONTROL_EVENT_CANCEL *|Generated on a client when a command has been received to cancel an LCE and the LCE has been moved to the 'Cancelled' or ' Deallocated' list - which list depends on whether an immediate or randomized end-time is specified in the

uMessage.sCancelLoadControlEvent field of the tsSE_DRLCCallBackMessage structure

| |SE_DRLC_LOAD_CONTROL_EVENT_CANCEL_ALL *|Generated on a client when a command has been received to cancel all LCEs and the LCEs have been moved to the 'Cancelled' or ' Deallocated' list - which list depends on whether an immediate or randomized end-time is specified in the

uMessage.sCancelLoadControlAllEvent field of the tsSE_DRLCCallBackMessage structure

| |SE_DRLC_REPORT_EVENT_STATUS **|Generated on the server when a Report Event Status message is received from a client - the contents of the report are included in the uMessage.sReportEvent field of the tsSE_DRLCCallBackMessage structure| |SE_DRLC_GET_SCHEDULED_EVENTS **|Generated on the server when a Get Scheduled Events message is received from a client - the contents of the request are included in the

uMessage.sGetScheduledEvents field of the tsSE_DRLCCallBackMessage structure

|

* If an LCE cancellation with a randomized end-time is required, the LCE is first moved to the 'Cancelled' list and the event is generated with randomized end-time specified. When the randomized end-time has been reached, the LCE is moved to the 'Deallocated' list and the event is generated again but with an immediate end-time specified. The application must then stop the corresponding load control.

** The server can identify which client has sent a Report Event Status or Get Scheduled Events message by examining the pZPSevent field of the tsZCL_CallBackEvent structure that contains the message.

E_SE_DRLC_EVENT_ACTIVE The E_SE_DRLC_EVENT_ACTIVE event is generated when an LCE has been moved from the 'Scheduled' list to the 'Active' list (see Section 41.4.2). The activated LCE is included in the uMessage.LoadControlEvent field of the tsSE_DRLCCallBackMessage structure.

E_SE_DRLC_EVENT_EXPIRED The E_SE_DRLC_EVENT_EXPIRED event is generated when an LCE has been moved from the 'Active' list (see Section 41.4.2). The expired LCE is included in the uMessage.LoadControlEvent field of the tsSE_DRLCCallBackMessage structure.

E_SE_DRLC_EVENT_CANCELLED The E_SE_DRLC_EVENT_CANCELLED event is generated when an LCE has been put in the 'Cancelled' list (see Section 41.4.2) as the result of an LCE 'cancel' or 'cancel all' command. Information on the cancelled LCE(s) is included in the uMessage.sCancelLoadControlEvent or uMessage.sCancelLoadControlAllEvent field of the tsSE_DRLCCallBackMessage structure, as appropriate.

Parent topic:DRLC Events

Other Elements of tsSE_DRLCCallBackMessage In addition to the fields eEventType and u8CommandId described in Section 41.7.1, the tsSE_DRLCCallBackMessage structure contains the following elements.

eDRLCStatus The eDRLCStatus field indicates the status returned from the command that has been executed (the command identified in u8CommandId). The status codes are enumerated in the teSE_DRLCStatus structure, shown below and described in Section 41.9.

```
typedef enum PACK
{
  E_SE_DRLC_DUPLICATE_EXISTS  = 0x80,
  E_SE_DRLC_EVENT_LATE,
```

(continues on next page)

(continued from previous page)

```
  E_SE_DRLC_EVENT_NOT_YET_ACTIVE,
  E_SE_DRLC_EVENT_OLD,
  E_SE_DRLC_NOT_FOUND,
  E_SE_DRLC_EVENT_NOT_FOUND,
  E_SE_DRLC_EVENT_IGNORED,
  E_SE_DRLC_CANCEL_DEFERRED,
  E_SE_DRLC_BAD_DEVICE_CLASS,
  E_SE_DRLC_BAD_CRITICALITY_LEVEL,
  E_SE_DRLC_DURATION_TOO_LONG,
  E_SE_DRLC_ENUM_END
} teSE_DRLCStatus;
```

u32CurrentTime The u32CurrentTime field contains the time (UTC) at which the event was generated.

uMessage This field is a union of structures, containing a structure for each of the DRLC command payloads. The valid structure in the event is defined by the value of u8CommandId (refer to the description of the E_SE_DRLC_EVENT_COMMAND event in Section 41.7.1).

Parent topic:DRLC Events

Parent topic:*Demand-Response and Load Control Cluster*

Functions The following DRLC cluster functions are provided:

- eSE_DRLCCreate
- eSE_DRLCAddLoadControlEvent
- eSE_DRLCGetScheduledEventsSend
- eSE_DRLCCancelLoadControlEvent
- eSE_DRLCCancelAllLoadControlEvents
- eSE_DRLCSetEventUserOption
- eSE_DRLCSetEventUserData
- eSE_DRLCGetLoadControlEvent
- eSE_DRLCFindLoadControlEvent

eSE_DRLCCreate

```
teZCL_Status eSE_DRLCCreate(
    bool_t bIsServer,
    uint8 u8NumberOfRecordEntries,
    uint8 *pu8AttributeControlBits,
    tsZCL_ClusterInstance *psClusterInstance,
    tsZCL_ClusterDefinition *psClusterDefinition,
    tsSE_DRLCCustomDataStructure
    *psCustomDataStructure,
    tsSE_DRLCLoadControlEventRecord
    *psDRLCLoadControlEventRecord,
    void *pvEndPointSharedStructPtr);
```

Description This function creates an instance of the DRLC cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function creates a DRLC cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions. For more details of creating cluster instances on custom endpoints, refer to *Appendix D.*

Note: This function must not be called for an endpoint on which a standard ZigBee device (example, IPD) will be used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function from those described in the *ZigBee Devices User Guide (JNUG3131)*.

When used, this function must be the first DRLC cluster function called in the application, and must be called after the stack has been started and after the ZCL has been initialized.

The function requires an array to be declared for internal use, which contains one element (of type **uint8)** for each attribute of the cluster. The array length should therefore equate to the total number of attributes supported by the DRLC cluster.

The function initializes the array elements to zero.

Parameters

- *bIsServer*: Type of cluster instance (server or client) to be created:
  - TRUE - server
  - FALSE - client
- *u8NumberOfRecordEntries*Number of LCEs that can be stored in the LCE list, one of:
  - SE_DRLC_NUMBER_OF_SERVER_LOAD_CONTROL_ENTRIES
  - SE_DRLC_NUMBER_OF_CLIENT_LOAD_CONTROL_ENTRIES
- *pu8AttributeControlBits*Pointer to an array of **uint8** values, with one element for each attribute in the cluster (see above).
- *psClusterInstance*Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initializing individual structure fields.
- *psClusterDefinition*Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the DRLC cluster. This parameter can refer to a pre-filled structure called sCLD_DRLC which is provided in the **DRLC.h** file.
- *psCustomDataStructure*Pointer to structure which contains custom data for the DRLC cluster. This structure is used for internal data storage. No knowledge of the fields of this structure is required.
- *psDRLCLoadControlEventRecord*
- Pointer to a structure in which an LCE is stored
- *pvEndPointSharedStructPtr*Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_DRLC which defines the attributes of DRLC cluster. The function initializes the attributes with default values.

Returns

- E_ZCL_SUCCESS

- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eSE_DRLCAddLoadControlEvent

```
teSE_DRLCStatus eSE_DRLCAddLoadControlEvent(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address psDestinationAddress,
    tsSE_DRLCLoadControlEvent *psLoadControlEvent,
    uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used on the DRLC cluster server to add an LCE (received from the utility company) to the 'Scheduled' list. The function also sends the LCE to the specified DRLC cluster client endpoints, where it will also be added to the 'Scheduled' list. Note that the LCE will be added to the 'Active' lists on the relevant devices if a 'start-time of now' is specified in the LCE.

The LCE should normally be sent to client endpoints that have been previously bound to the cluster server. This is done by specifying an address type of E_ZCL_AM_BOUND in the tsZCL_Address structure - in this case, the address field of this structure and the destination endpoint in the function call are both ignored.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which the LCE is sent
- *u8DestinationEndPointId*: Number of the remote endpoint to which the LCE is sent. Note that this parameter is ignored when sending to address types E_ZCL_AM_BOUND and E_ZCL_AM_GROUP
- *psDestinationAddress*: Pointer to a ZCL structure containing the address of the remote node to which the LCE is sent
- *psLoadControlEvent*: Pointer to a structure (see Section 41.11.1) which contains the LCE to be added and sent
- *pu8TransactionSequenceNumber*: Pointer to a location to store the Transaction Sequence Number (TSN) of the packet sent

Returns Any relevant DRLC return code listed in Section 41.9 or ZCL return code listed in Section 7.2

Parent topic: Functions

eSE_DRLCGetScheduledEventsSend

```
teSE_DRLCStatus eSE_DRLCGetScheduledEventsSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address psDestinationAddress,
    tsSE_DRLCGetScheduledEvents *psGetScheduledEvents,
    uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used on a DRLC cluster client to send a Get Scheduled Events message to the cluster server in order to request a list of scheduled (and active) LCEs. The function can be used to obtain the initial schedule of LCEs and to update the local LCE lists during operation (for example, if an End Device has been sleeping and has missed unsolicited LCE updates) - refer to Section 41.5.2.2 for more information on the use of this function.

As part of this function call, a tsSE_DRLCGetScheduledEvents structure must be provided which specifies the earliest start-time of the LCEs of interest and the maximum number of LCEs to be reported.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which the request is sent
- *u8DestinationEndPointId*: Number of the remote endpoint to which the request is sent (this must be the DRLC cluster server endpoint)
- *psDestinationAddress*: Pointer to a ZCL structure containing the address of the remote node to which the request is sent (this must be the address of the ESP)
- *psGetScheduledEvents*: Pointer to a structure which contains the LCE requirements of the request (see Section 41.11.2)
- *pu8TransactionSequenceNumber*: Pointer to a location to store the Transaction Sequence Number (TSN) of the request

Returns Any relevant DRLC return code listed in Section 41.9 or ZCL return code listed in Section 7.2

Parent topic: Functions

eSE_DRLCCancelLoadControlEvent

```
teSE_DRLCStatus eSE_DRLCCancelLoadControlEvent(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address psDestinationAddress,
    tsSE_DRLCCancelLoadControlEvent
    *psCancelLoadControlEvent,
    uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used on the DRLC cluster server to cancel an LCE. The LCE is cancelled locally and the cancellation is also sent to the specified DRLC cluster client endpoints. The LCE is ultimately moved to the 'Deallocated' list.

The cancellation request should normally be sent to client endpoints that have been previously bound to the cluster server. This is done by specifying an address type of E_ZCL_AM_BOUND in the tsZCL_Address structure - in this case, the address field of this structure and the destination endpoint in the function call are both ignored.

The LCE cancellation requirements are specified in the structure tsSE_DRLCCancelLoadControlEvent, including the applicable device class(es) and enrolment group(s), as well as an immediate or randomized end (for a full description of the end-time options, refer to Section 41.5.3).

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which the request is sent
- *u8DestinationEndPointId*: Number of the remote endpoint to which the request is sent. Note that this parameter is ignored when sending to address types E_ZCL_AM_BOUND and E_ZCL_AM_GROUP
- *psDestinationAddress*: Pointer to a ZCL structure containing the address of the remote node to which the request is sent
- *psCancelLoadControlEvent*: Pointer to a structure which contains the LCE cancellation requirements (see Section 41.11.3)
- *pu8TransactionSequenceNumber*: Pointer to a location to store the Transaction Sequence Number (TSN) of the request

Returns Any relevant DRLC return code listed in Section 41.9 or ZCL return code listed in Section 7.2

Parent topic: Functions

eSE_DRLCCancelAllLoadControlEvents

```
teSE_DRLCStatus eSE_DRLCCancelAllLoadControlEvents(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address psDestinationAddress,
    teSE_DRLCCancelControl eCancelEventControl,
    uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used on the DRLC cluster server to cancel all LCEs. The LCEs are cancelled locally and the cancellation is also sent to the specified DRLC cluster client endpoints. The LCEs are ultimately moved to the 'Deallocated' list.

The cancellation request should normally be sent to client endpoints that have been previously bound to the cluster server. This is done by specifying an address type of E_ZCL_AM_BOUND in the tsZCL_Address structure - in this case, the address field of this structure and the destination endpoint in the function call are both ignored.

The LCE cancellation end-time requirement must be specified as an immediate or randomized end (for a full description of the end-time options, refer to Section41.5.3).

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which the request is sent
- *u8DestinationEndPointId*: Number of the remote endpoint to which the request is sent. Note that this parameter is ignored when sending to address types E_ZCL_AM_BOUND and E_ZCL_AM_GROUP
- *psDestinationAddress*: Pointer to a ZCL structure containing the address of the remote node to which the request is sent
- *eCancelEventControl*: Enumeration indicating an immediate or randomized end, one of:
- E_SE_DRLC_CANCEL_CONTROL_IMMEDIATE
- E_SE_DRLC_CANCEL_CONTROL_USE_RANDOMISATION
- *pu8TransactionSequenceNumber*: Pointer to a location to store the Transaction Sequence Number (TSN) of the request

Returns Any relevant DRLC return code listed in Section 41.9 or ZCL return code listed in Section 7.2

Parent topic: Functions

eSE_DRLCSetEventUserOption

```
teSE_DRLCStatus eSE_DRLCSetEventUserOption(
    uint32 u32IssuerId,
    uint8 u8SourceEndPointId,
    teSE_DRLCUserEventOption eEventOption);
```

Description This function can be used on a DRLC cluster client to choose to participate or not participate in an individual LCE. By default, a client participates in an LCE, so normally this function only needs to be called if the client is to opt out of the LCE.

The function could be called following a button-press which results from a user decision to opt out of the LCE (for which information is displayed on the IPD screen).

When this function is called, a Report Event Status message is sent to the cluster server in order to indicate that the local client has opted out of the LCE. Once the LCE end-time has been reached, another Report Event Status message is sent to the server in order to confirm that the LCE has completed without the participation of the local client.

Parameters

- *u32IssuerId*: Identifier of the LCE (as issued by the utility company)
- *u8SourceEndPointId*: Number of the local endpoint where the LCE is located (endpoint corresponding to the DRLC cluster)
- *eEventOption*: Required option, one of:
  - E_SE_DRLC_EVENT_USER_OPT_IN (participate)
  - E_SE_DRLC_EVENT_USER_OPT_OUT (do not participate)

Returns Any relevant DRLC return code listed in Section 41.9 or ZCL return code listed in Section 7.2

Parent topic: Functions

eSE_DRLCSetEventUserData

```
teSE_DRLCStatus eSE_DRLCSetEventUserData(
    uint32 u32IssuerId,
    uint8 u8SourceEndPointId,
    teSE_DRLCUserEventSet eUserEventSetID,
    uint16 u16EventData);
```

Description This function can be used on a DRLC cluster client to locally modify the load control data of an LCE. Any one of the following data values can be changed:

- Criticality level
- Cooling temperature set-point
- Heating temperature set-point

- Load adjustment percentage
- Duty cycle

The function can be called multiple times to modify more than one of the above values. The data values are fully described in Section 41.11.1.

Parameters

- *u32IssuerId*: Identifier of the LCE (as issued by the utility company)
- *u8SourceEndPointId*: Number of the local endpoint where the LCE is located (endpoint corresponding to the DRLC cluster)
- *eUserEventSetID*: Identifier of the load control data item to be modified, one of:
  - E_SE_DRLC_CRITICALITY_LEVEL_APPLIED
  - E_SE_DRLC_COOLING_TEMPERATURE_SET_POINT_APPLIED
  - E_SE_DRLC_HEATING_TEMPERATURE_SET_POINT_APPLIED
  - E_SE_DRLC_AVERAGE_LOAD_ADJUSTMENT_PERCENTAGE_APPLIED
  - E_SE_DRLC_DUTY_CYCLE_APPLIED
- *u16EventData*: Value to which the specified data item is to be set (for formats of data values, refer to descriptions in Section 41.11.1)

Returns Any relevant DRLC return code listed in Section 41.9 or ZCL return code listed in Section 7.2

Parent topic: Functions

eSE_DRLCGetLoadControlEvent

```
teSE_DRLCStatus eDRLCGetLoadControlEvent(
    uint8 u8SourceEndPointId,
    uint8 u8TableIndex,
    teSE_DRLCEventList eEventList,
    tsSE_DRLCLoadControlEvent **ppsLoadControlEvent);
```

Description This function can be used to obtain an LCE from a local LCE list.

The required list must be specified as one of ‘Scheduled’, ‘Active’, ‘Cancelled’ and ‘Deallocated’. The index of the required LCE in the list must also be specified. The index of zero is used to indicate that the LCE with the oldest start-time should be retrieved. To retrieve all the LCEs in a list, repeatedly call this function with index zero until the function indicates that there are no further LCEs in the list (returns E_SE_DRLC_EVENT_NOT_FOUND).

Parameters

- *u8SourceEndPointId*: Number of the local endpoint from which the LCE is to be retrieved (endpoint corresponding to the DRLC cluster)
- *u8TableIndex*: Index of required LCE in the specified LCE list (see below)
- *eEventList*: LCE list from which the LCE is to be retrieved, one of:
  - E_SE_DRLC_EVENT_LIST_SCHEDULED
  - E_SE_DRLC_EVENT_LIST_ACTIVE

  - E_SE_DRLC_EVENT_LIST_CANCELLED
  - E_SE_DRLC_EVENT_LIST_DEALLOCATED
- *ppsLoadControlEvent*Pointer to a pointer to a tsSE_DRLCLoadControlEvent structure to receive the obtained LCE (see Section 41.11.1)

Returns Any relevant DRLC return code listed in Section 41.9 or ZCL return code listed in Section 7.2

Parent topic: Functions

eSE_DRLCFindLoadControlEvent

```
teSE_DRLCStatus eSE_DRLCFindLoadControlEvent(
uint8 u8SourceEndPointId,
uint32 u32IssuerId,
bool_t bIsServer,
tsSE_DRLCLoadControlEvent **ppsLoadControlEvent,
teSE_DRLCEventList *peEventList);
```

Description This function can be used to obtain the specified LCE from the local LCE lists.

The required LCE must be specified in terms of its identifier issued by the utility company. The function will search all the local LCE lists, identify the list (if any) in which the LCE was found and return the found LCE.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint from which the LCE is to be retrieved (endpoint corresponding to the DRLC cluster)
- *u32IssuerId*: Identifier of the LCE to be found (as issued by the utility company)
- *bIsServer*: Cluster server or client:
  - TRUE - server
  - FALSE - client
- *ppsLoadControlEvent*Pointer to a pointer to a tsSE_DRLCLoadControlEvent structure to receive the obtained LCE (see Section 41.11.1)
- *peEventList*: Pointer to variable to receive enumerated value of the list in which the LCE was found (see Section 41.10.7)

Returns Any relevant DRLC return code listed in Section 41.9 or ZCL return code listed in Section 7.2

Parent topic: Functions

Parent topic:*Demand-Response and Load Control Cluster*

Return codes In addition to some of the ZCL status enumerations (detailed in Section 7.2), the following enumerations are returned by the DRLC cluster functions (described in Section 41.8) to indicate the outcome of the function call.

```
typedef enum PACK
{
 E_SE_DRLC_DUPLICATE_EXISTS = 0x80,
 E_SE_DRLC_EVENT_LATE,
 E_SE_DRLC_EVENT_NOT_YET_ACTIVE,
 E_SE_DRLC_EVENT_OLD,
 E_SE_DRLC_NOT_FOUND,
 E_SE_DRLC_EVENT_NOT_FOUND,
 E_SE_DRLC_EVENT_IGNORED,
 E_SE_DRLC_CANCEL_DEFERRED,
 E_SE_DRLC_BAD_DEVICE_CLASS,
 E_SE_DRLC_BAD_CRITICALITY_LEVEL,
 E_SE_DRLC_DURATION_TOO_LONG,
 E_SE_DRLC_ENUM_END
} teSE_DRLCStatus;
```

The above return codes are described in the table below.

Enumeration	Description
E_SE_DRLC_DUPLICATE_EXISTS	An overlapping LCE (in time) has been found
E_SE_DRLC_EVENT_LATE	Function call refers to a time period that is earlier than the current ZCL time
E_SE_DRLC_EVENT_NOT_YET_A	Not used - reserved for future use
E_SE_DRLC_EVENT_OLD	Not used - reserved for future use
E_SE_DRLC_NOT_FOUND	LCE cannot be found in lists (used in LCE cancelation or opt out)
E_SE_DRLC_EVENT_NOT_FOUN	LCE cannot be found in lists (used when searching for an LCE)
E_SE_DRLC_EVENT_IGNORED	Not used - reserved for future use
E_SE_DRLC_CANCEL_DEFERRE	Cancellation has been processed but is deferred to act in the future
E_SE_DRLC_BAD_DEVICE_CLAS	Specified device class not recognized
E_SE_DRLC_BAD_CRITICALITY_	Specified criticaility level not recognized
E_SE_DRLC_DURATION_TOO_L	Specified duration exceeds maximum of 1440 minutes (one day)

Parent topic:*Demand-Response and Load Control Cluster*

Enumerations

'Device Class' Enumerations The device classes that are used in load control are enumerated in the teSE_DRLCDeviceClassFieldBitmap structure below:

```
typedef enum
{
  E_SE_DRLC_HVAC_COMPRESSOR_OR_FURNACE_BIT = 0x00,
  E_SE_DRLC_STRIP_BASEBOARD_HEATERS_BIT,
  E_SE_DRLC_WATER_HEATER_BIT,
  E_SE_DRLC_POOL_PUMP_SPA_JACUZZI_BIT,
  E_SE_DRLC_SMART_APPLIANCES_BIT,
  E_SE_DRLC_IRRIGATION_PUMP_BIT,
  E_SE_DRLC_MANAGED_COMMERCIAL_AND_INDUSTRIAL_LOADS_BIT,
  E_SE_DRLC_SIMPLE_MISC_LOADS_BIT,
  E_SE_DRLC_EXTERIOR_LIGHTING_BIT,
  E_SE_DRLC_INTERIOR_LIGHTING_BIT,
```

(continues on next page)

(continued from previous page)

```
  E_SE_DRLC_ELECTRIC_VEHICLE_BIT,
  E_SE_DRLC_GENERATION_SYSTEMS_BIT,
  E_SE_DRLC_DEVICE_CLASS_FIRST_RESERVED_BIT
} teSE_DRLCDeviceClassFieldBitmap;
```

The device class enumerations are listed and described in the table below.

Device Class Enumeration	Description
E_SE_DRLC_HVAC_COMPRESSOR_OR_FURNACE_BIT	HVAC compressor or furnace
E_SE_DRLC_STRIP_BASEBOARD_HEATERS_BIT	Strip/baseboard heater
E_SE_DRLC_WATER_HEATER_BIT	Water heater
E_SE_DRLC_POOL_PUMP_SPA_JACUZZI_BIT	Pool/spa/jacuzzi pump
E_SE_DRLC_SMART_APPLIANCES_BIT	Smart appliance
E_SE_DRLC_IRRIGATION_PUMP_BIT	Irrigation pump
E_SE_DRLC_MANAGED_COMMERCIAL_AND_INDUSTRIAL_	Managed Commercial & Industrial (C&I)
E_SE_DRLC_SIMPLE_MISC_LOADS_BIT	Simple miscellaneous (residential on/off)
E_SE_DRLC_EXTERIOR_LIGHTING_BIT	Exterior lighting
E_SE_DRLC_INTERIOR_LIGHTING_BIT	Interior lighting
E_SE_DRLC_ELECTRIC_VEHICLE_BIT	Electric vehicle
E_SE_DRLC_GENERATION_SYSTEMS_BIT	Generation systems
E_SE_DRLC_DEVICE_CLASS_FIRST_RESERVED_BIT	Reserved

Parent topic: Enumerations

'DRLC Event' Enumerations The event types generated by the DRLC cluster are enumerated in the teSE_DRLCCallBackEventType structure below:

```
typedef enum PACK
{
  E_SE_DRLC_EVENT_API =0x00,
  E_SE_DRLC_EVENT_COMMAND,
  E_SE_DRLC_EVENT_ACTIVE,
  E_SE_DRLC_EVENT_EXPIRED,
  E_SE_DRLC_EVENT_CANCELLED,
  E_SE_DRLC_EVENT_ENUM_END,
} teSE_DRLCCallBackEventType;
```

The above event types are described in the table below.

Event Type Enumeration	Description
E_SE_DRLC_EVENT_API	Reserved for internal use
E_SE_DRLC_EVENT_COM	Generated when a command has been received from either the cluster server or a cluster client
E_SE_DRLC_EVENT_ACT	Generated when an LCE has been added to the 'Active' list
E_SE_DRLC_EVENT_EXP	Generated when an LCE has been removed from the 'Active' list
E_SE_DRLC_EVENT_CAN	Generated when an LCE has been put in the 'Cancelled' list

DRLC events are described in more detail in Section 41.7.

Parent topic: Enumerations

'Criticality Level' Enumerations The criticality levels that are available for an LCE are enumerated in the teSE_DRLCCriticalityLevels structure below:

```
typedef enum
{
    E_SE_DRLC_RESERVED_0_CRITICALITY = 0x00,
    E_SE_DRLC_GREEN_CRITICALITY,
    E_SE_DRLC_VOLUNTARY_1_CRITICALITY,
    E_SE_DRLC_VOLUNTARY_2_CRITICALITY,
    E_SE_DRLC_VOLUNTARY_3_CRITICALITY,
    E_SE_DRLC_VOLUNTARY_4_CRITICALITY,
    E_SE_DRLC_VOLUNTARY_5_CRITICALITY,
    E_SE_DRLC_EMERGENCY_CRITICALITY,
    E_SE_DRLC_PLANNED_OUTAGE_CRITICALITY,
    E_SE_DRLC_SERVICE_DISCONNECT_CRITICALITY,
    E_SE_DRLC_UTILITY_DEFINED_1_CRITICALITY,
    E_SE_DRLC_UTILITY_DEFINED_2_CRITICALITY,
    E_SE_DRLC_UTILITY_DEFINED_3_CRITICALITY,
    E_SE_DRLC_UTILITY_DEFINED_4_CRITICALITY,
    E_SE_DRLC_UTILITY_DEFINED_5_CRITICALITY,
    E_SE_DRLC_UTILITY_DEFINED_6_CRITICALITY,
    E_SE_DRLC_FIRST_RESERVED_CRITICALITY
} teSE_DRLCCriticalityLevels;
```

The above criticality levels are described in the table below.

Criticality Level Enumeration	Description
E_SE_DRLC_RESI	Reserved for future use
E_SE_DRLC_GRE	**Green:** Indicates that there will be a significant contribution from non-green sources during the LCE - participation in the LCE is voluntary
E_SE_DRLC_VOL	**Voluntary 1-6:** Represent increasing levels of load reduction as move through levels 1 to 6, as defined by the utility company - intended to be used in a sequence of LCEs to gradually reduce loads, where participation in the LCEs is voluntary
E_SE_DRLC_VOL	
E_SE_DRLC_VOL	
E_SE_DRLC_VOL	
E_SE_DRLC_VOL	
E_SE_DRLC_EME	**Emergency:** Indicates that the LCE represents an emergency situation (normally demanding the termination of all non-essential loads, as defined by the utility company) - participation in the LCE is mandatory
E_SE_DRLC_PLA	**Planned Outage:** Indicates that the LCE represents an intentional outage (normally demanding the termination of all non-essential loads, as defined by the utility company) - participation in the LCE is mandatory
E_SE_DRLC_SER	**Service Disconnect:** Indicates that the LCE represents a service disconnection (normally demanding the termination of all non-essential loads, as defined by the utility company) - participation in the LCE is mandatory
E_SE_DRLC_UTII	**Utility-defined 1-6:** Criticality levels completely defined by the utility company - participation in the LCE is voluntary
E_SE_DRLC_UTII	
E_SE_DRLC_UTII	
E_SE_DRLC_UTII	
E_SE_DRLC_UTII	
E_SE_DRLC_UTII	
E_SE_DRLC_FIRS	Reserved for future use

Parent topic: Enumerations

'LCE Cancellation' Enumerations The cancelation options (immediate or randomized) that are available for an LCE are enumerated in the teSE_DRLCCancelControl structure below:

```
typedef enum PACK
{
   E_SE_DRLC_CANCEL_CONTROL_IMMEDIATE =0x00,
   E_SE_DRLC_CANCEL_CONTROL_USE_RANDOMISATION =0x10
} teSE_DRLCCancelControl;
```

The above options are described in the table below.

LCE Cancellation Enumeration	Description
E_SE_DRLC_C/	LCE is cancelled immediately by moving it directly to the 'Deallocated' list - a randomized end-time configured in the LCE is ignored
E_SE_DRLC_C/	A random delay will be applied to the LCE cancellation, if a randomised end-time was configured in the LCE - the LCE is moved to the 'Cancelled' list where it will stay (and remain valid) until the random delay has expired, when it will be moved to the 'Deallocated' list (an upper limit on the delay is defined in the cluster - see Section41.2)

Parent topic: Enumerations

'LCE Participation' Enumerations The options to participate or not participate in an LCE are enumerated in the teSE_DRLCUserEventOption structure below:

```
typedef enum PACK
{
   E_SE_DRLC_EVENT_USER_OPT_IN =0x00,
   E_SE_DRLC_EVENT_USER_OPT_OUT
} teSE_DRLCUserEventOption;
```

The above options are described in the table below.

LCE Participation Enumeration	Description
E_SE_DRLC_EVE]	User has opted not to participate in the LCE. The device sends this message and does not adjust the load when the LCE becomes active.
E_SE_DRLC_EVE]	User has opted to participate in the LCE. The device only sends this message following an OPT_OUT (when the user has changed their mind and decided to participate after all)

Parent topic: Enumerations

'LCE Data Modification' Enumerations The load control data items that can be locally modified in an LCE are enumerated in the teSE_DRLCUserEventSet structure below:

```
typedef enum PACK
{
   E_SE_DRLC_CRITICALITY_LEVEL_APPLIED =0x00,
   E_SE_DRLC_COOLING_TEMPERATURE_SET_POINT_APPLIED,
   E_SE_DRLC_HEATING_TEMPERATURE_SET_POINT_APPLIED,
   E_SE_DRLC_AVERAGE_LOAD_ADJUSTMENT_PERCENTAGE_APPLIED,
   E_SE_DRLC_DUTY_CYCLE_APPLIED,
   E_SE_DRLC_USER_EVENT_ENUM_END,
} teSE_DRLCUserEventSet;
```

The above options are described in the table below (the data items are fully described in Section 41.11.1).

LCE Participation Enumeration	Description
E_SE_DRLC_CRITICALITY_LEVEL_APPLIED	Specifies that 'criticality level' is to be modified.
E_SE_DRLC_COOLING_TEMPERATURE_SET_PC	Specifies that 'cooling temperature set-point' is to be modified
E_SE_DRLC_HEATING_TEMPERATURE_SET_PC	Specifies that 'heating temperature set-point' is to be modified
E_SE_DRLC_AVERAGE_LOAD_ADJUSTMENT_PI	Specifies that 'average load adjustment percentage' is to be modified
E_SE_DRLC_DUTY_CYCLE_APPLIED	Specifies that 'duty cycle' is to be modified

Parent topic: Enumerations

'LCE List' Enumerations The LCE lists are enumerated in the teSE_DRLCEventList structure below:

```
typedef enum PACK
{
    E_SE_DRLC_EVENT_LIST_SCHEDULED =0x00,
    E_SE_DRLC_EVENT_LIST_ACTIVE,
    E_SE_DRLC_EVENT_LIST_CANCELLED,
    E_SE_DRLC_EVENT_LIST_DEALLOCATED,
    E_SE_DRLC_EVENT_LIST_NONE
} teSE_DRLCEventList;
```

The above lists are described in the table below.

LCE List Enumeration	Description
E_SE_DRLC_EVENT_LI	**Scheduled list:** Contains LCEs that are due to be executed in the future
E_SE_DRLC_EVENT_LI	**Active list:** Contains LCEs that are currently being executed
E_SE_DRLC_EVENT_LI	**Cancelled list:** Contains LCEs that have been cancelled with a randomized end-time and whose random end-time has not yet been reached
E_SE_DRLC_EVENT_LI	**Deallocated list:** Contains expired LCEs and therefore a record of the free storage for LCEs

Parent topic: Enumerations

'LCE Status' Enumerations LCE status is enumerated in the teSE_DRLCEventStatus structure below:

```
typedef enum PACK
{
    E_SE_DRLC_LOAD_CONTROL_EVENT_COMMAND_RECIEVED =0x01,
    E_SE_DRLC_EVENT_STARTED,
    E_SE_DRLC_EVENT_COMPLETED,
    E_SE_DRLC_USER_CHOSEN_OPT_OUT,
    E_SE_DRLC_USER_CHOSEN_OPT_IN,
    E_SE_DRLC_EVENT_HAS_BEEN_CANCELLED,
    E_SE_DRLC_EVENT_HAS_BEEN_SUPERSEDED,
    E_SE_DRLC_EVENT_PARTIALLY_COMPLETED_WITH_USER_OPT_OUT,
    E_SE_DRLC_EVENT_PARTIALLY_COMPLETED_WITH_USER_OPT_IN,
    E_SE_DRLC_EVENT_COMPLETED_NO_USER_PARTICIPATION,
```

(continues on next page)

(continued from previous page)

```
    E_SE_DRLC_REJECTED_INVALID_CANCEL_COMMAND_DEFAULT =0xF8,
    E_SE_DRLC_REJECTED_INVALID_CANCEL_COMMAND_INVALID_EFFECTIVE_TIME,
    E_SE_DRLC_REJECTED_EVENT_RECEIVED_AFTER_IT_HAD_EXPIRED =0xFB,
    E_SE_DRLC_REJECTED_INVALID_CANCEL_COMMAND_UNDEFINED_EVENT=0xFD,
    E_SE_DRLC_LOAD_CONTROL_EVENT_COMMAND_REJECTED,
    E_SE_DRLC_EVENT_STATUS_ENUM_END
} teSE_DRLCEventStatus;
```

The above enumerations are described in the table below.

Enumeration	Description
E_SE_DRLC_LOAD_CONTROL_EVENT_COM-MAND_RECEIVED	LCE command received (to add new LCE to local lists)
E_SE_DRLC_EVENT_STARTED	LCE has started
E_SE_DRLC_EVENT_COMPLETED	LCE has completed
E_SE_DRLC_USER_CHOSEN_OPT_OUT	Client has opted out of the LCE
E_SE_DRLC_USER_CHOSEN_OPT_IN	Client has opted into the LCE
E_SE_DRLC_EVENT_HAS_BEEN_CANCELLE	LCE has been cancelled
E_SE_DRLC_EVENT_HAS_BEEN_SUPERSEDI	LCE has been replaced with another LCE
E_SE_DRLC_EVENT_PARTIALLY_COMPLETI	LCE has prematurely completed due to a client opt-out during the LCE
E_SE_DRLC_EVENT_PARTIALLY_COMPLETI	LCE has completed but was only partially executed due to a client opt-in during the LCE
E_SE_DRLC_EVENT_COMPLETED_NO_USER	LCE has completed but there was no client participation (due to a client opt-out from the start)
E_SE_DRLC_REJECTED_INVALID_CANCEL_C	Received ‘cancel command’ invalid and rejected (default)
E_SE_DRLC_REJECTED_INVALID_CANCEL_C	Received ‘cancel command’ rejected due to invalid effective time (start-time of cancellation)
E_SE_DRLC_REJECTED_EVENT_RECEIVED_A	LCE was received after it had expired (current time is greater than start-time + duration)
E_SE_DRLC_REJECTED_INVALID_CANCEL_C	Received ‘cancel command’ due to undefined LCE
E_SE_DRLC_LOAD_CONTROL_EVENT_COM-MAND_REJECTED	LCE command rejected

Parent topic: Enumerations

Parent topic:*Demand-Response and Load Control Cluster*

Structures

tsSE_DRLCLoadControlEvent The structure of type tsSE_DRLCLoadControlEvent contains the parameters of a Load Control Event (LCE), as shown and described below.

```
typedef struct {
 uint8    u8UtilityEnrolmentGroup;
 uint8    u8CriticalityLevel;
 uint8    u8CoolingTemperatureOffset;
 uint8    u8HeatingTemperatureOffset;
 uint8    u8AverageLoadAdjustmentSetPoint;
 uint8    u8DutyCycle;
 uint8    u8EventControl;
 uint16   u16DeviceClass;
```

(continues on next page)

(continued from previous page)

```
 uint16   u16DurationInMinutes;
 uint16   u16CoolingTemperatureSetPoint;
 uint16   u16HeatingTemperatureSetPoint;
 uint32   u32IssuerId;
 uint32   u32StartTime;
}tsSE_DRLCLoadControlEvent;
```

where:

- u8UtilityEnrolmentGroup identifies the group of devices to which the LCE applies - an 'enrolment group' is defined by the utility company. The identifier 0x00 is reserved to indicate 'all groups'.
- u8CriticalityLevel is a value representing the level of criticality of the LCE. Enumerations are provided for the different levels and are detailed in Section 41.10.3.
- u8CoolingTemperatureOffset (optional) specifies the required temperature offset, in units of 0.1oC, above the current temperature set-point of a cooling device (example, 0x5 represents a temperature offset of 0.5oC). The setting 0xFF is used to indicate that no offset is required.
- u8HeatingTemperatureOffset (optional) specifies the required temperature offset, in units of 0.1oC, below the current temperature set-point of a heating device (example, 0x14 represents a temperature offset of 2.0oC). The setting 0xFF is used to indicate that no offset is required.
- u8AverageLoadAdjustmentSetPoint (optional) specifies the maximum permissible load as an offset from the consumer's average load, where this offset is expressed as a positive or negative percentage in units of 1% (e.g. 20% allows loads of up to 120% of the average while -10% allows loads of up to 90% of the average). The offset has a valid range of -100% to +100% and is represented in two's complement form (e.g. 15% is represented by 0x0F and

  -5% is represented by 0xFB). The value 0x80 is used to indicate that no such limit is required.
- u8DutyCycle (optional) specifies the percentage duty cycle for the load supplied to the device - that is, the percentage of the LCE duration for which the load will be supplied (e.g. for a duty cycle of 80%, the supplied device will be 'on' for 80% of the duration of the LCE). The manner in which the duty cycle is implemented (e.g. periodicity) is device-specific. The valid range of duty cycle values is 0 to 100. The setting 0xFF indicates that no duty cycling is required.
- u8EventControl specifies whether a randomised start-time and/or randomised end-time are required for the LCE. The following bit-masks are provided to allow the start-time and end-time of an LCE to be individually randomised (they can be bitwise-ORed to randomize both times):

```
#define SE_DRLC_CONTROL_RANDOMISATION_START_TIME_MASK   (0x01)
#define SE_DRLC_CONTROL_RANDOMISATION_STOP_TIME_MASK (0x02)
```

- u``16DeviceClass identifies the class(es) of device to which the LCE applies. Enumerations are provided for the various device classes, which may be combined in a bitwise-OR operation, and are detailed in Section 41.10.1.
- u16DurationInMinutes specifies the duration, in minutes, of the LCE (although the actual duration will be longer than the specified duration if a randomized end-time is required). The maximum possible duration that can be specified is 1440 minutes (one day).
- u16CoolingTemperatureSetPoint (optional) specifies the required temperature set-point, in units of 0.01oC, for a cooling device, where a negative temperature is represented in two's complement form (e.g. a temperature of 20oC is represented by 0x07D0 and -40oC is repre-

sented by 0xF060). The valid temperature range is -273.15°C to 327.67°C. The setting 0x8000 is used to indicate that no temperature set-point is required.

- u16HeatingTemperatureSetPoint (optional) specifies the required temperature set-point, in units of 0.01oC, for a heating device, where a negative temperature is represented in two's complement form (for example, a temperature of 25oC is represented by 0x09C4 and -1oC is represented by 0xFFFF). The valid temperature range is -273.15°C to 327.67°C. The setting 0x8000 is used to indicate that no temperature set-point is required.
- u32IssuerId is a unique identifier for the LCE, issued by the utility company (the value could be based on the time-stamp of when the LCE was issued).
- u``32StartTime represents the start-time (UTC) of the LCE (although the actual start-time is later if a randomized start-time is required). The value 0x000000000 is used to indicate a 'start-time of now'.

Parent topic: Structures

tsSE_DRLCGetScheduledEvents The structure of type tsSE_DRLCGetScheduledEvents contains the parameters of a **Get Scheduled Event** message, as shown and described below.

```
typedef struct {
   uint32 u32StartTime;
   uint8 u8numberOfEvents;
} tsSE_DRLCGetScheduledEvents;
```

where:

- u32StartTime is the earliest start-time (UTC) of the requested LCEs
- u8numberOfEvents is the maximum number of LCEs to report

Parent topic: Structures

tsSE_DRLCCancelLoadControlEvent The structure of type tsSE_DRLCCancelLoadControlEvent contains the parameters of a Cancel LCE command, as shown and described below.

```
typedef struct {
    uint32    u32IssuerId;
    uint16    u16DeviceClass;
    uint8     u8UtilityEnrolmentGroup;
    teSE_DRLCCancelControl  eCancelControl;
    uint32    u32effectiveTime;
} tsSE_DRLCCancelLoadControlEvent;
```

where:

- u32IssuerId is the identifier (provided by the utility company) of the LCE to be canceled
- u16DeviceClass is a bitmap indicating the device class(es) to which the LCE cancelation applies - enumerations for the device classes are provided, as described in Section 41.10.1
- u8UtilityEnrolmentGroup is the enrolment group of the devices to which the LCE cancelation applies
- eCancelControl indicates whether to honour a randomised end that has been configured in the LCE - enumerations are provided, as described in Section 41.10.4
- u32effectiveTime is the time (UTC) from which the LCE cancelation is effective

Parent topic: Structures

tsSE_DRLCReportEvent The structure of type tsSE_DRLCReportEvent contains the parameters of a Report Event Status message, as shown and described below.

```
typedef struct {
    uint8    u8EventStatus;
    uint8    u8AverageLoadAdjustmentPercentageApplied;
    uint8    u8DutyCycleApplied;
    uint8    u8EventControl;
    uint8    u8SignatureType;
    uint8    u8CriticalityLevelApplied;
    bool_t   bSignatureVerified;
    uint16   u16CoolingTemperatureSetPointApplied;
    uint16   u16HeatingTemperatureSetPointApplied;
    uint32   u32IssuerId;
    uint32   u32EventStatusTime;
    tsSE_DRLCOctets      sSignature;
} tsSE_DRLCReportEvent;
```

where:

- u8EventStatus is the reported LCE status - enumerations are provided and described in Section 41.10.8
- u8AverageLoadAdjustmentPercentageApplied is an optional field containing the load adjustment percentage applied by the sending client (if the user has chosen to over-ride the original setting in the LCE) - for the format of this setting, refer to the equivalent field description in Section 41.11.1 (0x80 indicates that the field is not used)
- u8DutyCycleApplied is an optional field containing the percentage duty cycle applied by the sending client (if the user has chosen to over-ride the original setting in the LCE) - for the format of this setting, refer to the equivalent field description in Section 41.11.1 (0xFF indicates that the field is not used)
- u8EventControl is a bitmap which specifies whether a randomised start-time and/or randomised end-time are configured for the LCE:

Bit	Description
0	1 = randomised start-time, 0 = immediate start-time
1	1 = randomised end-time, 0 = immediate end-time
2-7	Not used

- u8SignatureType is the type of algorithm, if any, used to create the signature for the Report Event Status message (only one algorithm, ECDSA, is currently supported):

```
#define SE_DRLC_NO_SIGNATURE (0x00)
#define SE_DRLC_SIGNATURE_TYPE_ECDSA      (0x01)
```

- u8CriticalityLevelApplied is the criticality level of the LCE - enumerations are provided and described in Section 41.10.3
- bSignatureVerified is filled in by the recipient of the Report Event Status message (therefore, the DRLC cluster server) to indicate whether the signature of the message has been verified and is valid:

  TRUE - verified and valid

  FALSE - verified and not valid, or not verified
- u16CoolingTemperatureSetPointApplied is an optional field containing the cooling temperature applied by the sending client (if the user has chosen to over-ride the original setting in

the LCE) - for the format of this setting, refer to the equivalent field description in Section 41.11.1 (0x8000 indicates that the field is not used)

- u16HeatingTemperatureSetPointApplied is an optional field containing the heating temperature applied by the sending client (if the user has chosen to over-ride the original setting in the LCE) - for the format of this setting, refer to the equivalent field description in Section 41.11.1 (0x8000 indicates that the field is not used)
- u32IssuerId is the unique identifier for the LCE, as issued by the utility company
- u``32EventStatusTime is the time (UTC) at which the Report Event Status message was issued
- s``Signature is the signature for the Report Event Status message - this is the concatenation of two ECDSA signature components (r,s)

Note: It is recommended that signatures are supported by your application for backward compatibility.

Parent topic: Structures

tsSE_DRLCCallBackMessage The structure of type tsSE_DRLCCallBackMessage contains a DRLC callback event. It is shown below but described in Section 41.7.

```
typedef struct
{
  teSE_DRLCCallBackEventType  eEventType;
  uint8 u8CommandId;
  teSE_DRLCStatus  eDRLCStatus;
  uint32      u32CurrentTime;
  union {
   tsSE_DRLCLoadControlEvent       sLoadControlEvent;
   tsSE_DRLCCancelLoadControlEvent      sCancelLoadControlEvent;
   tsSE_DRLCCancelLoadControlAllEvent   sCancelLoadControlAllEvent;
   tsSE_DRLCReportEvent     sReportEvent;
   tsSE_DRLCGetScheduledEvents     sGetScheduledEvents;
    } uMessage;
} tsSE_DRLCCallBackMessage;
```

Parent topic: Structures

Parent topic:*Demand-Response and Load Control Cluster*

Compile-time options This section describes the compile-time options that may be enabled in the **zcl_options.h** file of an application that uses the DRLC cluster.

The DRLC cluster is enabled by defining CLD_DRLC.

Client and server versions of the cluster are defined by DRLC_CLIENT and DRLC_SERVER, respectively.

Length of LCE Lists The number of LCEs that may be stored in an LCE list (see Section 41.4.2) is, by default, three. This default can be over-ridden on the cluster server and a cluster client by assigning the desired values to the macros:

SE_DRLC_NUMBER_OF_SERVER_LOAD_CONTROL_ENTRIES (server)

SE_DRLC_NUMBER_OF_CLIENT_LOAD_CONTROL_ENTRIES (client)

LCE Re-sends The DRLC cluster server may re-send an LCE when it becomes active in order to support clients that do not have a clock. This facility should not be enabled unless explicitly required. To enable this functionality, define:

DRLC_SEND_LCE_AGAIN_AT_ACTIVE_TIME

Message Signing (Security) On DRLC cluster clients that need to implement message signing (see Section 41.6), the following must be defined:

```
#define SE_MESSAGE_SIGNING
```

For a DRLC cluster server to check a message signature, it is necessary to locally store the certificates of any nodes that perform key establishment. The maximum number of certificates that can be stored is configured by defining the following on the server:

```
#define KEC_NUM_CERTIFICATES <       n>
```

where n is the number of certificates that can be stored.

Parent topic:*Demand-Response and Load Control Cluster*

Simple Metering Cluster This chapter outlines the Simple Metering cluster, which is used to handle information relating to the measured consumption of some resource, which may be electricity, gas, heat or water.

The Simple Metering cluster has a Cluster ID of 0x0702.

Overview The Simple Metering cluster is required in ZigBee devices as indicated in the table below.

	Server-side	Client-side
Mandatory in...	Metering Device	
Optional in...	ESP	ESP

IPD

PCT

|

Thus, a Metering Device or ESP can use this cluster to store attributes and respond to commands relating to these attributes. An IPD or PCT may use this cluster to issue commands to interact with remote attributes held on a Metering Device or ESP.

The Simple Metering cluster is enabled by defining CLD_SIMPLE_METERING in the **zcl_options.h** file. Further compile-time options for the Simple Metering cluster are detailed in Section 42.12.

The information that can potentially be stored in this cluster is organized into the following attribute sets:

- Reading Information Set (resource measurement information)
- TOU Information Set (Time-Of-Use information)
- Meter Status
- Formatting (data formatting/interpretation guidance)

- Historical Consumption
- Load Profile Configuration
- Supply Limit
- Block Information (for future use - not certifiable in SE 1.1.1 or earlier)
- Alarms (for future use - not certifiable in SE 1.1.1 or earlier)

This information is stored in both mandatory and optional attributes - see Section 42.3.

Note: Many of the Simple Metering cluster attributes are not certifiable in SE 1.1.1 (07-5356-17) or earlier and are reserved for future use (as indicated in Section 42.2).

Parent topic:*Simple Metering Cluster*

Simple Metering Cluster structure and attributes The Simple Metering cluster is contained in the following tsSE_SimpleMetering structure:

```
typedef struct
{
    /* Reading information attribute set attribute ID's (D.3.2.2.1) */
    zuint48             u48CurrentSummationDelivered;         /

where:

'Reading Information' Attribute Set

- u48CurrentSummationDelivered is the total amount of the measured resource (e.g. electrical energy) delivered to the premises so far, expressed in the units specified in eUnitOfMeasure and in the format specified in u8SummationFormatting
- The following are optional attributes and are fully described in the *ZigBee Smart Energy*

Profile Specification:

```
u48CurrentSummationReceived
u48CurrentMaxDemandDelivered
u48CurrentMaxDemandReceived
u48DFTSummation
u16DailyFreezeTime
i8PowerFactor
utctReadingSnapshotTime
utctCurrentMaxDemandDeliveredTime
utctCurrentMaxDemandReceivedTime
```

- The following are optional attributes that relate to Fast Polling mode (*both attributes are not certifiable in SE 1.1.1 or earlier and are for future use*):
  - u32DefaultUpdatePeriod is the default poll-period, in seconds, that is used in updating metering data outside of fast polling episodes
  - u8FastPollUpdatePeriod is the minimum poll-period, in seconds, that can be used in updating metering data during fast polling episodes (should not be set to less than 2 seconds)
- The following are optional attributes and are fully described in the *ZigBee Smart Energy Profile Specification*(*these attributes are not certifiable in SE 1.1.1 or earlier and are for future use*):

```
u48CurrentBlockPeriodConsumptionDelivered
u24DailyConsumptionTarget
e8CurrentBlock
```

- The following are optional attributes that relate to the 'Get Profile' feature:
  - eProfileIntervalPeriod is the time-interval over which one set of consumption data will be collected
  - u32IntervalReadReportingPeriod is the time-interval, in minutes, after which a sleepy End Device should wake up to provide metering data
- The following are optional attributes are fully described in the *ZigBee Smart Energy Profile Specification* (*all these attributes except*u8SupplyStatus *are not certifiable in SE 1.1.1 or earlier and are for future use*):

```
u16PresetReadingTime
u16VolumePerReport
u8FlowRestriction
u8SupplyStatus
u48CurrentInletEnergyCarrierSummation
u48CurrentOutletEnergyCarrierSummation
i16InletTemperature
i16OutletTemperature
i16ControlTemperature
i24CurrentInletEnergyCarrierDemand
i24CurrentOutletEnergyCarrierDemand
```

'Time-Of-Use (TOU) Information' Attribute Set

- The following are optional attributes and are fully described in the *ZigBee Smart Energy Profile Specification*(*the attributes for tiers 7 to 15 are not certifiable in SE 1.1.1 or earlier and are for future use*):

```
u48CurrentTier1SummationDelivered

```

'Meter Status' Attribute Set

- u``8MeterStatus is an 8-bit bitmap representing the status of the meter. Enumerated masks are provided that correspond to the possible settings - see Section 42.10.2*(this attribute is only certifiable for electricity meters in SE 1.1.1)*
- The following are optional attributes and are fully described in the *ZigBee Smart Energy Profile Specification*(*all the attributes are not certifiable in SE 1.1.1 or earlier and are for future use*):

```
u8RemainingBatteryLife
u24HoursInOperation
u24HoursInFault
```

'Formatting' Attribute Set

- eUnitOfMeasure indicates the unit of measure for the resource quantity contained above in u48CurrentSummationDelivered and below in i24InstantaneousDemand. Enumerations for the possible units are provided - see Section 42.10.3
- The following are optional attributes and are fully described in the *ZigBee Smart Energy Profile Specification*:

```
u24Multiplier
u24Divisor
```

- u8SummationFormatting indicates the formatting for the resource quantity contained above in u48CurrentSummationDelivered. Enumerations for the possible formats are provided - see Section 42.10.4
- The following are optional attributes and are fully described in the *ZigBee Smart Energy Profile Specification*:

```
u8DemandFormatting
u8HistoricalConsumptionFormatting
```

- eMeteringDeviceType indicates the type of Metering Device in terms of the resource type which it measures. Enumerations for the possible device types are provided - see Section 42.10.6
- The following pair of elements represents an optional attribute which identifies the location of a Metering Device (*this attribute is not certifiable in SE 1.1.1 or earlier and is for future use*):

  - sSiteId is a tsZCL_OctetString structure containing information on the site identifier. This element is paired with au8SiteId (below)
  - au8SiteId is an array containing the site identifier. This element is paired with sSiteId (above)

Note: This identifier is known in the UK as the M-PAN for electricity and MPRN for gas, and in South Africa as as the 'Stand Point'. The field is large enough to accommodate the number of characters typically used in the UK and Europe (16 digits).

- The following pair of elements represents an optional attribute, which indicates the serial number of a Metering Device (*this attribute is not certifiable in SE 1.1.1 or earlier and is for future use*):
  - sMeterSerialNumber is a tsZCL_OctetString structure containing information on the serial number of a Metering Device. This element is paired with au8SiteId (below)
  - au8MeterSerialNumber is an array containing the serial number of a Metering Device. This element is paired with sMeterSerialNumber (above)
- The following are optional attributes and are fully described in the *ZigBee Smart Energy Profile Specification*(*these attributes are not certifiable in SE 1.1.1 or earlier and are for future use*):

```
e8EnergyCarrierUnitOfMeasure
u8EnergyCarrierSummationFormatting
u8EnergyCarrierDemandFormatting
e8TemperatureUnitOfMeasure
u8TemperatureFormatting
```

'Historical Consumption' Attribute Set

- i24InstantaneousDemand is an optional attribute containing the current rate of consumption of the metered resource with respect to time. The unit of measure for the relevant resource is as specified in eUnitOfMeasure
  - If this attribute is used, the metering application should update its value on a regular basis, between once every second and once every five seconds. The attribute value can be negative, meaning that the relevant resource is currently being supplied from the premises to the utility company - for example, the case of locally generated electricity from roof-mounted solar panels being supplied to the national grid.
- The following are optional attributes and are fully described in the *ZigBee Smart Energy Profile Specification*:

```
u24CurrentDayConsumptionDelivered
u24CurrentDayConsumptionReceived
u24PreviousDayConsumptionDelivered
u24PreviousDayConsumptionReceived
utctCurrentPartialProfileIntervalStartTimeDelivered
utctCurrentPartialProfileIntervalStartTimeReceived
u24CurrentPartialProfileIntervalValueDelivered
u24CurrentPartialProfileIntervalValueReceived
```

- The following are optional attributes and are fully described in the *ZigBee Smart Energy Profile Specification*(*these attributes are not certifiable in SE 1.1.1 or earlier and are for future use*):

```
u48CurrentDayMaxPressure
u48CurrentDayMinPressure
u48PreviousDayMaxPressure
```

(continues on next page)

(continued from previous page)

Parent topic:*Simple Metering Cluster*

Attribute Settings The Simple Metering cluster contains both mandatory and optional attributes (see Section 42.2). The cluster structure is shown below with only the mandatory attributes (which are enabled by default):

```
typedef struct PACK
{
  zuint48                 u48CurrentSummationDelivered;
  zbmap8                  u8MeterStatus;
  teSE_UnitOfMeasure      eUnitOfMeasure;
  zbmap8                  u8SummationFormatting;
  teSE_MeteringDeviceType eMeteringDeviceType;
} tsSE_SimpleMetering;
```

The mandatory attribute settings are outlined below.

eMeteringDeviceType The element eMeteringDeviceType of the structure tsSE_SimpleMetering indicates the type of Metering Device in terms of the resource type which it measures: electricity, gas, water, heat, cooling or pressure. This attribute belongs to the cluster's Formatting attribute set.

Enumerated values are provided for the full range of possible metering devices - for example, E_CLD_SM_MDT_GAS for a gas meter. Enumerated values are also provided for devices that mirror a Metering Device - for example, E_CLD_SM_MDT_GAS_MIRRORED for the mirroring device of a gas meter. All of these enumerations are defined in the structure teCLD_SM_MeteringDeviceType, detailed in Section 42.10.6.

u8MeterStatus The element u8MeterStatus of the structure tsSE_SimpleMetering indicates the current status of the device by means of an 8-bit value. This attribute has its own attribute set, Meter Status.

The status value is a bitmap with the bit representations indicated in the table below:

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
Reserved	Service						

Disconnect

Open *

|Leak Detect|Power Quality|Power

Failure

|Tamper Detect|Battery Low|Check Meter|

* Set to '1' when service to this site has been disconnected

A bit is set (to '1') to indicate the corresponding error or warning.

A number of macros are defined to reflect the above bit settings - for example, E_CLD_SM_METER_STATUS_POWER_FAILURE_BIT contains the state of the Power Failure bit (Bit 3). There are also macros for masking off the appropriate bit - these macros are detailed in Section 42.10.2.

eUnitOfMeasure The element eUnitOfMeasure of the structure tsSE_SimpleMetering indicates the unit of measure in which the relevant resource is metered, e.g. kiloWatt-hour for electricity. This attribute belongs to the cluster's Formatting attribute set.

Enumerated values are provided for the possible units of measure - for example, E_CLD_SM_UOM_CUBIC_METER for cubic metre (of gas or water). This example will also configure measurements to be expressed in binary/hex. However, enumerated values are also provided to configure measurements to be expressed in binary coded decimal - for example, E_CLD_SM_UOM_CUBIC_METER_BCD configures measurements in cubic metres and expressed in binary coded decimal. All of these enumerations are defined in the structure teCLD_SM_UnitOfMeasure, detailed in Section 42.10.3.

u8SummationFormatting The element u8SummationFormatting of the structure tsSE_SimpleMetering is an 8-bit value indicating the position of the decimal point in the metered value (see *u48CurrentSummationDelivered*). This attribute belongs to the cluster's Formatting attribute set.

This value contains bit fields, as follows:

- **Bits 2-0:** 3-bit value indicating number of digits to right of point
- **Bits 6-3:** 3-bit value indicating number of digits to left of point
- **Bit 7:** Setting this bit (to '1') suppresses leading zeros

A number of macros are defined to accommodate the above format information - these macros are detailed in Section 42.10.4.

u48CurrentSummationDelivered The element u48CurrentSummationDelivered of the structure tsSE_SimpleMetering is a 48-bit value representing the total quantity consumed, so far, of the metered resource (e.g. electrical energy). This attribute belongs to the Reading Information attribute set.

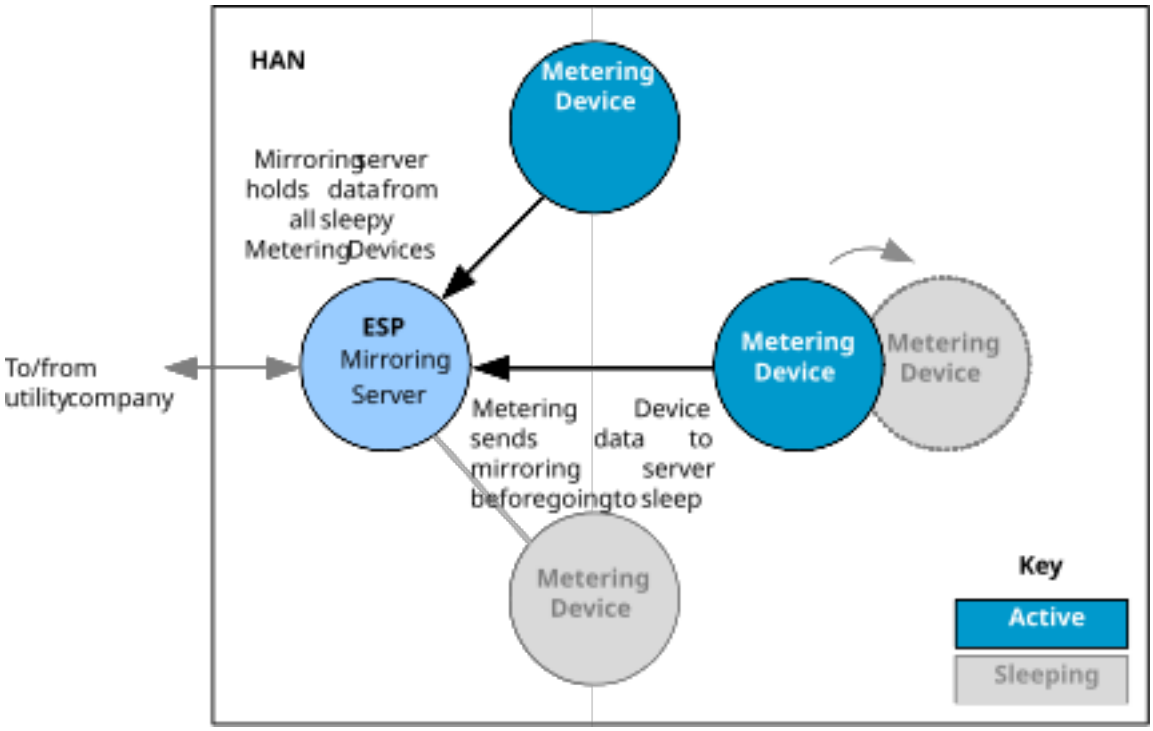
The attribute value is interpreted with the aid of the elements eUnitOfMeasure and u8SummationFormatting, which indicate the unit of measure and the position of the decimal point respectively.

Parent topic:*Simple Metering Cluster*

Remotely Reading Simple Metering Attributes Dedicated functions are provided for remotely reading the Simple Metering attributes:

1. The application must first call **eSE_ReadMeterAttributes()** to submit a 'read attributes' request to the relevant remote endpoint. The resulting read process is as described for **eZCL_SendReadAttributesRequest()** in Section 2.3.2.

2. On receiving the 'read attributes' response, the event E_ZCL_CBET_READ_ATTRIBUTES_RESPONSE is generated, which causes the callback function for the local endpoint to be invoked. This callback function should include a call to **eSE_HandleReadAttributesResponse()** which checks whether all the Simple Metering attributes are included in the response. If the response is not complete, the function re-sends 'read attributes' requests until all attribute values are obtained.

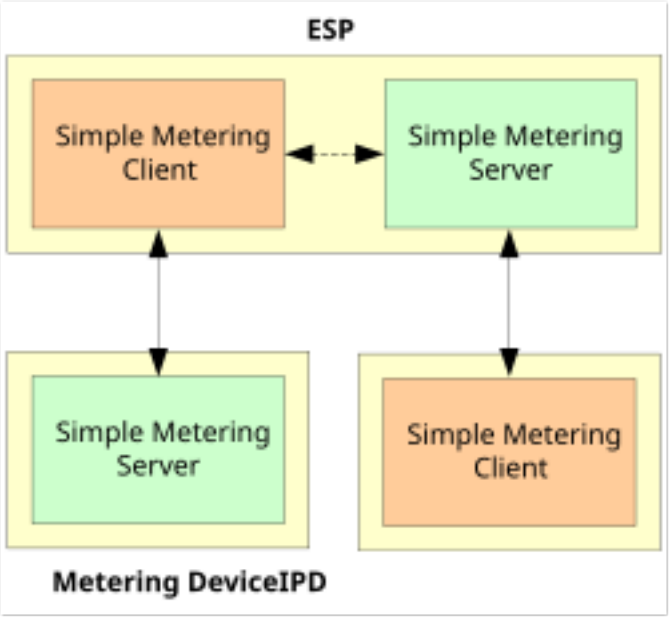


Note that read access to cluster attributes must be explicitly enabled at compile-time as described in Section 1.3.

Parent topic:*Simple Metering Cluster*

Mirroring Metering Data 'Mirroring' is a facility that stores and provides access to metering data which originates from Metering Devices that sleep. A Metering Device cannot be accessed during periods of sleep and therefore its data cannot normally be read at these times. Mirroring involves holding the data from sleepy Metering Devices centrally on a server, allowing access to the data at all times.

Normally, the ESP (Co-ordinator) acts as the mirroring server. One or more sleepy Metering Devices (End Devices) can mirror their data on this server. A Metering Device must send its latest data to the mirroring server immediately before entering sleep mode. This is illustrated in the figure below.



Mirroring of Metering Data

Every mirror (one for each Metering Device) on the mirroring server has its own endpoint. The maximum number of mirror endpoints is defined at compile-time (see Section 42.12). Note that these endpoints are in addition to the main endpoint for the ESP (registered using **eSE_RegisterEspMeterEndPoint()** or **eSE_RegisterEspEndPoint()**).

Mirroring versions of the Simple Metering cluster server and/or client are implemented on the mirror endpoints. This is illustrated in the figure below, where the ESP, as the mirroring server, incorporates both the Simple Metering cluster server and client, the Metering device incorporates a cluster server and the IPD incorporates a cluster client.

Simple Metering Cluster in Mirroring

The ESP device structure tsSE_EspMeterDevice contains a section on mirroring support which includes an array of tsSE_Mirror structures (see Section 42.11.2). This array contains one element/structure per mirror endpoint, with the first mirror endpoint occupying array element 0 and the array size corresponding to the maximum number of mirror endpoints allowed on the mirroring server. The information stored in an array element includes the IEEE address of the Metering Device to which the mirror endpoint has been allocated.

Configuring Mirroring on ESP The ESP normally acts as the mirroring server, containing a unique mirror endpoint for each (mirrored) Metering Device. Configuration of the mirroring server is carried out both within the application that runs on the device and as compile-time options - refer to Section 42.12 for the relevant compile-time options.

On the ESP, mirroring can be enabled in the application code when the device is registered using the function **eSE_RegisterEspMeterEndPoint()** or **eSE_RegisterEspEndPoint()**. These functions require specification of the first endpoint that is to be used for mirroring. Starting at this endpoint, consecutive endpoints to be used for mirrors are reserved, up to the maximum number of mirrors defined by the compile-time option CLD_SM_NUMBER_OF_MIRRORS. For example, if 5 is specified as the first mirror endpoint and up to 4 mirrors can be used then endpoints 5, 6, 7 and 8 are reserved for mirrors. Note that mirroring is disabled by setting the start endpoint to 0.

Note: The endpoints reserved for mirroring must also be included in the configuration diagram in the ZPS Configuration Editor. However, they must not be enabled since they are enabled when mirrors are created on them.

The tsSE_Mirror structures in the ESP device structure tsSE_EspMeterDevice contain the IEEE addresses of the Metering Devices being mirrored on the ESP (these IEEE addresses are automatically initialised to zero). The ESP application must save an array of these IEEE addresses to non-volatile memory using the NVM module - this will allow the mirrored Metering Devices to be identified by the mirroring server following a reset of the ESP.

The ESP must allocate mirror endpoints to Metering Devices in response to requests from the Metering Devices (refer to Section 42.5.2 for details of requesting a mirror), as described below:

1. On receiving a mirror request on the ESP, the ZCL automatically allocates the next available mirror endpoint to the Metering Device (the IEEE address of the Metering Device is automatically written to the tsSE_Mirror structure which corresponds to the allocated mirror endpoint).

2. The event E_CLD_SM_CLIENT_RECEIVED_COMMAND containing the command E_CLD_SM_REQUEST_MIRROR is then generated on the ESP, causing the callback function on the ESP to be invoked.
3. The callback function must check whether all mirror endpoints have now been exhausted, in order to update the relevant status on the ESP. To do this, the function **eSM_GetFreeMirrorEndPoint()** must be called to obtain the number of the next free mirror endpoint. If the value 0xFFFF is returned, this means that no more mirror endpoints are available (for subsequent requests) and the attribute u8PhysicalEnvironment of the Basic cluster must be set to zero (to indicate to other Metering Devices that no more mirrors are available on the ESP). This step is illustrated in the code fragment below.

```
eSM_GetFreeMirrorEndPoint (&u16FoundEP);
if (u16FoundEP == 0xFFFF)
{
        psSE_EspMeterDevice->sBasicCluster.u8PhysicalEnvironment = 0x00;
}
else
{
        psSE_EspMeterDevice->sBasicCluster.u8PhysicalEnvironment = 0x01;
}
```

4. The callback function must copy the IEEE addresses from the tsSE_Mirror structures (which are automatically kept up-to-date) to the application's array of IEEE addresses for mirrored devices, and this array should be re-saved in non-volatile memory using the NVM module. This step is illustrated below in the code fragment under "*Writing and Preserving Array of IEEE Addresses*".
5. A response is automatically sent to the requesting Metering Device, where this response contains the number of the assigned endpoint.

The ESP is then ready to receive metering data from the remote Metering Device, as described in Section 42.5.3.

Writing and Preserving Array of IEEE Addresses The ESP application must maintain an array of the IEEE addresses of the mirrored Metering Devices and keep a copy of this array in NVM. The array can be updated from the tsSE_Mirror structures for the mirror endpoints and saved to NVM as illustrated in the code fragment below:

```
case E_UPDATE_EVENT_REQUEST_MIRROR:
case E_UPDATE_EVENT_REMOVE_MIRROR:
{
  uint8 u8LoopCntr;
  for (u8LoopCntr =0; u8LoopCntr < CLD_SM_NUMBER_OF_MIRRORS; u8LoopCntr++)
     {
       sMirrorState.u64ExtAddr[u8LoopCntr] =
                sMeter.sSE_Mirrors[u8LoopCntr].u64SourceAddress;
     }
     sMirrorState.bNetworkUp = TRUE;
    NvSaveOnIdle(&sMirrorState, TRUE);
}
break;
```

Recreating Mirrors Following an ESP Reset If the ESP is reset, the mirrors that have been created on the device are lost. However, if the IEEE addresses (of the mirrored Metering Devices) associated with the mirror endpoints have been preserved in NVM, this data can be read by the ESP application following the reset and the mirrors recreated. Given the relevant endpoint number and IEEE address, a mirror can be recreated using the function **eSM_CreateMirror()**.

Note: A matching function **eSM_RemoveMirror()**also exists to allow the application to remove a mirror.

Parent topic: Mirroring Metering Data

Configuring Mirroring on Metering Devices Configuration of a Metering Device for mirroring is carried out both within the application that runs on the device and as a compile-time option - refer to Section42.12 for the relevant compile-time options.

It is the responsibility of the Metering Device to request a mirror on the ESP, but first it must establish whether the ESP is accepting mirror requests. To do this, the application should use the function **eZCL_SendReadAttributesRequest()** to obtain the value of the u8PhysicalEnvironment attribute of the Basic cluster on the ESP - if this value is non-zero then the ESP is open to receiving mirror requests.

Provided that the ESP is accepting mirror requests, a Metering Device application can request a mirror using the function **eSM_ServerRequestMirrorCommand()**. This function sends a mirror request to the ESP with the aim of being allocated a mirror endpoint. The handling of this request on the ESP is described in Section 42.5.1.

The Metering Device application must then wait for a response from the ESP. This response is indicated by the event E_CLD_SM_SERVER_RECEIVED_COMMAND containing the command E_CLD_SM_REQUEST_MIRROR_RESPONSE, causing the callback function for the receiving endpoint to be invoked.

If the request has resulted in the successful allocation of a mirror endpoint on the ESP, the tsSM_RequestMirrorResponseCommand structure (see Section 42.11.6) in this event will contain the allocated endpoint number. In this case:

- The callback function should write the allocated endpoint number and mirroring server (ESP) IEEE address to non-volatile memory for persistent data storage using the NVM module.
- The Metering Device application can now send metering data for storage on the ESP whenever required, as described in Section 42.5.3.

Note: If the Metering Device subsequently requests another mirror on the same ESP, the same mirror endpoint number will be returned - a Metering Device cannot have more than one mirror on the same ESP.

If the request did not result in an allocated mirror endpoint on the ESP, the endpoint number returned in the above structure will be 0xFFFF and no action needs to be taken by the callback function.

Parent topic: Mirroring Metering Data

Mirroring Data Once a mirror for a Metering Device has been set up, as described in Section 42.5.1 and Section 42.5.2, the mirror can be populated and refreshed with data in two ways:

- The ESP application can submit a 'read attributes' request to the Metering Device (when it is not asleep), as described in Section 2.3.2.
- The Metering Device can send metering data as unsolicited attribute reports to the mirror at any time (for example, before entering sleep mode). This method is described further below.

The Metering Device application sends unsolicited attribute reports for the Simple Metering cluster to the mirror using the function **eZCL_ReportAllAttributes()**, described in Section 5.2.

On receiving this data, the event E_ZCL_CBET_ATTRIBUTE_REPORT_MIRROR is generated on the ESP, causing the callback function on the ESP to be invoked. The callback function must then check that the data has come from a valid source (a Metering Device which has a mirror on the

ESP) by calling the function **eSM_IsMirrorSourceAddressValid()**. According to the outcome of this check, the function updates the event status:

```
sZCL_CallBackEvent.uMessage.sReportAttributeMirror.eStatus
```

- If eStatus is set to E_ZCL_ATTR_REPORT_OK, the reported attribute values (metering data) are automatically stored on the relevant mirror endpoint and an E_ZCL_CBET_REPORT_INDIVIDUAL_ATTRIBUTE event is generated for each attribute reported.
- If eStatus is set to anything else, a ZCL default response is automatically sent back to the reporting device to indicate that mirroring is not authorised for this device (E_ZCL_CMDS_NOT_AUTHORIZED).

Maintaining the Mirrored eMeteringDeviceType Attribute When a mirror is created on the ESP, the Simple Metering cluster attribute eMeteringDeviceType in the mirror will be set to the appropriate value for the Metering Device to be mirrored (e.g. E_CLD_SM_MDT_GAS). However, in order to distinguish the mirror cluster on the ESP from the original cluster on the Metering Device, the ESP application must replace this value in the mirror with the equivalent '_MIRRORED' value (e.g. E_CLD_SM_MDT_GAS_MIRRORED). In fact, this replacement must be performed every time the ESP receives a new set of attribute values from the Metering Device (by either of the two methods described above), since this attribute value in the mirror will be over-written each time and must subsequently be corrected.

Parent topic: Mirroring Metering Data

Reading Mirrored Data A ZigBee device such as an IPD may need to obtain data from a mirror on the ESP, particularly when the mirrored Metering Device is sleeping. The data is requested by means of the standard 'read attributes' method, described in Section 2.3.2 - that is, by calling the ZCL function **eZCL_SendReadAttributesRequest()** on the requesting device.

If an attempt is made to read an attribute that currently has no value in the mirror, the resulting E_ZCL_CBET_READ_INDIVIDUAL_ATTRIBUTE_RESPONSE event will contain the attribute status E_ZCL_CMDS_UNSUPPORTED_ATTRIBUTE.

Parent topic: Mirroring Metering Data

Removing a Mirror The removal of a mirror on the ESP is initiated by the application on the corresponding Metering Device using the function **eSM_ServerRemoveMirrorCommand()**. This function sends a 'remove mirror' request to the relevant mirror endpoint on the ESP.

Note: A mirror can be removed from an endpoint on the ESP but the endpoint will remain reserved for mirroring - it may later be re-assigned to another mirror.

On receiving this request, the ESP processes the request as follows:

1. The ZCL first verifies the source address of the request to ensure that it has come from the Metering Device which corresponds to the mirror to be removed. If the source address is not valid then a ZCL default response is automatically sent to the requesting Metering Device to indicate that the request was not authorised (E_ZCL_CMDS_NOT_AUTHORIZED) - otherwise, the ESP continues to process the request as described in the steps below.
2. The ZCL then removes the mirror from the specified endpoint, thus freeing the endpoint for future use by another mirror.
3. The event E_CLD_SM_CLIENT_RECEIVED_COMMAND containing the command E_CLD_SM_REMOVE_MIRROR is generated on the ESP, causing the callback function on the ESP to be invoked.

4. The callback function must set the u8PhysicalEnvironment attribute of the Basic cluster to 0x01 in order to indicate that the ESP has the capacity to accept mirror requests (since the removal of the mirror leaves at least one mirror endpoint free).
5. The callback function must copy the IEEE addresses from the tsSE_Mirror structures (which are automatically kept up-to-date) to the application's array of IEEE addresses for mirrored devices, and this array should be re-saved in non-volatile memory using the NVM module. This step is illustrated in the code fragment under "Writing and Preserving Array of IEEE Addresses" on page 1011.
6. A response is automatically sent to the requesting Metering Device to confirm the mirror removal.

The response (reporting successful mirror removal) results in the generation of the event E_CLD_SM_SERVER_RECEIVED_COMMAND containing the command E_CLD_SM_MIRROR_REMOVED on the Metering Device.

Note: The function **eSM_RemoveMirror()** is also provided, which allows the ESP application to directly remove a mirror.

Parent topic: Mirroring Metering Data

Parent topic:*Simple Metering Cluster*

Consumption Data Archive ('Get Profile') Devices that support the Simple Metering cluster can maintain and exchange historical consumption (profiling) data using the 'Get Profile' feature. A consumption data archive, which is distinct from the data of the Simple Metering cluster attributes, is maintained in a circular buffer on the cluster server. A cluster client can make a 'Get Profile' request to the server to obtain data from this archive. Normally, the cluster server is implemented on a Metering Device and the cluster client is implemented on an IPD. Typically, the IPD requests a consumption history from the Metering Device in order to display this information to the consumer.

The consumption data in the archive corresponds to a series of consecutive time intervals with their corresponding consumption values. Thus, the archive consists of the last few consumption measurements - it is the responsibility of the application running on the server device to update the archive (see Section 42.6.1).

If the 'Get Profile' feature is required, it must be enabled in the compile-time options as described in Section 42.12. These options include the maximum number of consumption intervals that can be archived on the server (and therefore requested).

Updating Consumption Data on Server The consumption archive is held on the Smart Metering cluster server in a circular buffer operating on a FIFO basis. This buffer provides storage space for a sequence of entries containing consumption data for consecutive time intervals, where each buffer entry is a structure of the type tsSEGetProfile consisting of:

- End-time of consumption interval (as UTC time)
- Units delivered to the customer
- Units received from the customer (when customer sells units to utility company)

The maximum number of entries that can be stored in the buffer is determined at compile-time (see Section 42.12). When a new entry is added to a full buffer, this entry replaces the oldest entry currently in the buffer.

The application must keep the buffer up-to-date by adding a new entry using the function **eSM_ServerUpdateConsumption()**. Before this function is called, the relevant consumption data must be updated in one or both of the following Simple Metering cluster attributes:

```
u24CurrentPartialProfileIntervalValueDelivered
```

- Contains the number of units delivered to the customer over the last interval

```
u24CurrentPartialProfileIntervalValueReceived
```

- Contains the number of units received from the customer over the last interval

An attribute only needs to be updated if the corresponding consumption has been implemented (for example, the utility company often only delivers units to the customer and does not receive any from the customer).

eSM_ServerUpdateConsumption() takes the current time as an input and then adds an entry containing the consumption data (in the above attributes) to the buffer, where the supplied current time becomes the end-time in the entry (thus, the duration of the consumption intervals is dictated by the frequency at which this function is called - see below).

Note: The current time can be obtained by the application using the function **u32ZCL_GetUTCTime()**, described in Section 18.7.

eSM_ServerUpdateConsumption() must be called periodically by the application. The period must match the value to which the Simple Metering eProfileIntervalPeriod attribute has been set (see Section 42.2). Standard periods, ranging from 2.5 minutes to one day, are provided as a set of enumerations (see Section 42.10.10).

Parent topic: Consumption Data Archive ('Get Profile')

Sending and Handling a 'Get Profile' Request The application on a device which supports the Simple Metering cluster as a client, such as an IPD, can send a 'Get Profile' request to the cluster server by calling the function **eSM_ClientGetProfileCommand()**. This function allows consumption data to be requested from the archive for one or more intervals.

The inputs for this function include:

- A value indicating whether the units delivered or units received (by the utility company) are being requested (see Section 42.6.1)
- An end-time (as a UTC time) - the most recent consumption data will be reported which has an end-time equal to or earlier than this end-time (a specified end-time of zero will result in the most recent consumption data)
- The number of consumption intervals to report (this number will be reported only if data for sufficient intervals is available) - the end-time rule, specified above, will be applied to all the reported intervals

On receiving the request, the event E_CLD_SM_SERVER_RECEIVED_COMMAND containing the command E_CLD_SM_GET_PROFILE is generated on the server, causing the callback function on the device to be invoked (for a Metering Device, this is the callback function registered through **eSE_RegisterEspMeterEndPoint()** or **eSE_RegisterMeterEndPoint()**). The callback function only needs to be concerned with this event if the archive data needs to be modified before the ZCL automatically sends the requested data in a 'Get Profile' response. The response indicates the number of consumption intervals reported and contains the consumption data for these intervals, as well as the end-time of the most recent interval reported.

On receiving the response, the event E_CLD_SM_CLIENT_RECEIVED_COMMAND containing the command E_CLD_SM_GET_PROFILE_RESPONSE is generated on the requesting client, causing the callback function on the device to be invoked (for an IPD, this is the callback function registered through **eSE_RegisterIPDEndPoint()**). The callback function should extract the requested data from the event using the function **u32SM_GetReceivedProfileData()** in order to process or store the data. This function should be called for each consumption interval reported in the event - the code fragment below illustrates repeated calls to the function until all the reported data has been obtained:

```
for (i =0 ;i < sGetProfileResponseCommand.u8NumberOfPeriodsDelivered; i
++)
{
   //Read data from event
X(i)= u32SM_GetReceivedProfileData(tsSM_
↪GetProfileResponseCommand *psSMGetProfileResponseCommand)
}
```

Alternatively, the function can be called repeatedly until it returns 0xFFFFFFFF, which indicates that there is no more data to be extracted from the event.

Parent topic: Consumption Data Archive ('Get Profile')

Parent topic:*Simple Metering Cluster*

Simple Metering Events The Simple Metering cluster has its own events that are handled through the callback mechanism described in *Chapter 3*. If a device uses the Simple Metering cluster then Simple Metering event handling must be included in the callback function for the associated endpoint, where this callback function is registered through the relevant endpoint registration function (for example, through **eSE_RegisterMeterEndPoint()** for a standalone Metering Device). The relevant callback function will then be invoked when a Simple Metering event occurs.

For a Simple Metering event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to a tsSM_CallBackMessage structure which contains the Simple Metering parameters:

```
typedef struct
{
  teSM_CallBackEventType eEventType;
  uint8 u8CommandId;
    union
    {
      tsSM_GetProfileResponseCommand      sGetProfileResponseCommand;
      tsSM_RequestFastPollResponseCommand     sRequestFastPollResponseCommand;
      tsSM_GetProfileRequestCommand      sGetProfileCommand;
      tsSM_RequestMirrorResponseCommand     sRequestMirrorResponseCommand;
      tsSM_MirrorRemovedResponseCommand     sMirrorRemovedResponseCommand;
      tsSM_RequestFastPollCommand       sRequestFastPollCommand;
      tsSM_Error            sError;
    }uMessage;
}tsSM_CallBackMessage;
```

Information on the elements of the above structure is provided below.

Event Types The eEventType field of the tsSM_CallBackMessage structure specifies the type of Simple Metering event that has been generated. These event types are enumerated in the teSM_CallBackEventType structure (see Section 42.10.7) and are listed in the table below.

Event Type Enumeration	Description
E_CLD_SM_CLIENT_RECEIVED_C(	Generated when a command has been received on a cluster client
E_CLD_SM_SERVER_RECEIVED_C	Generated when a command has been received on the cluster server
E_CLD_SM_FAST_POLLING_TIME	Generated on the cluster server at the end of a fast polling episode (*for future use*)

The possible command types for the above event types are listed in Section 42.7.2.

Parent topic: Simple Metering Events

Command Types For each event type listed in Section 42.7.1, one of a number of command types could have been received. The relevant command type is specified through the u8CommandId field of the tsSM_CallBackMessage structure. The possible command types for each event type are detailed below.

E_CLD_SM_CLIENT_RECEIVED_COMMAND The E_CLD_SM_CLIENT_RECEIVED_COMMAND event is generated when a command has been received on a cluster client. The possible command types for this event type are listed in the table below, which gives the enumerations and the associated uMessage union elements in the tsSM_CallBackMessage structure:

u8CommandId Enumeration	uMessage Union Element
E_CLD_SM_GET_PROFILE_RESPONSE	sGetProfileResponseCommand
E_CLD_SM_REQUEST_MIRROR	sRequestMirrorAdd
E_CLD_SM_REMOVE_MIRROR	sRequestMirrorRemove
E_CLD_SM_REQUEST_FAST_POLL_MODE_	

RESPONSE

|sRequestFastPollResponseCommand

(*for future use*)

| |E_CLD_SM_CLIENT_ERROR|sError|

The above command enumerations are fully described in Section 42.10.8.

E_CLD_SM_SERVER_RECEIVED_COMMAND The E_CLD_SM_SERVER_RECEIVED_COMMAND event is generated when a command has been received on the cluster server. The possible command types for this event type are listed in the table below, which gives the enumerations and the associated uMessage union elements in the tsSM_CallBackMessage structure:

u8CommandId Enumeration	uMessage Union Element
E_CLD_SM_GET_PROFILE	sGetProfileCommand
E_CLD_SM_REQUEST_MIRROR_RESPONSE	sRequestMirrorResponseCommand
E_CLD_SM_MIRROR_REMOVED	sMirrorRemovedResponseCommand
E_CLD_SM_REQUEST_FAST_POLL_MODE	sRequestFastPollCommand (*for future use*)
E_CLD_SM_SERVER_ERROR	sError

The above command enumerations are fully described in Section 42.10.9.

E_CLD_SM_FAST_POLLING_TIMER_EXPIRED The E_CLD_SM_FAST_POLLING_TIMER_EXPIRED event is generated on the cluster server at the end of a fast polling episode. It has no associated data structure. *Fast polling is not certifiable in SE 1.1.1 or earlier and this event is reserved for future use.*

Parent topic: Simple Metering Events

Parent topic:*Simple Metering Cluster*

Functions The following Simple Metering cluster functions are provided:

1. eSE_SMCreate
2. eSE_ReadMeterAttributes
3. eSE_HandleReadMeterAttributesResponse
4. eSM_ServerRequestMirrorCommand
5. eSM_ServerRemoveMirrorCommand
6. eSM_CreateMirror
7. eSM_RemoveMirror
8. eSM_GetFreeMirrorEndPoint
9. eSM_IsMirrorSourceAddressValid
10. eSM_ServerUpdateConsumption
11. eSM_ClientGetProfileCommand
12. u32SM_GetReceivedProfileData

eSE_SMCreate

```
teZCL_Status eSE_SMCreate(
    uint8 u8Endpoint,
    bool_t bIsServer,
    uint8 *pu8AttributeControlBits,
    tsZCL_ClusterInstance *psClusterInstance,
    tsZCL_ClusterDefinition *psClusterDefinition,
    tsSM_CustomStruct *psCustomDataStruct,
    void *pvEndPointSharedStructPtr);
```

Description This function creates an instance of the Simple Metering cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function will create a Simple Metering cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions. For more details of creating cluster instances on custom endpoints, refer to *Appendix D.*

Note: This function must not be called for an endpoint on which a standard ZigBee device (for example, an IPD) is used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function from those described in the *ZigBee Devices User Guide (JNUG3131).*

When used, this function must be the first Simple Metering cluster function called in the application, and must be called after the stack has been started and after the ZCL has been initialized.

The function requires an array to be declared for internal use, which contains one element (of type **uint8**) for each attribute of the cluster. The array length should therefore equate be the total number of attributes supported by the Simple Metering cluster, which can be obtained by using the macro SM_NUM_OF_ATTRIBUTES.

The array declaration should be as follows:

```
uint8 au8AppSMClusterAttributeControlBits[SM_NUM_OF_ATTRIBUTES];
```

The function initializes the array elements to zero.

Parameters

- *u8Endpoint*: Number of local endpoint on which the cluster instance is to be created, in the range 1 to 240.
- *bIsServer* : Type of cluster instance (server or client) to be created:
- : TRUE - server
- : FALSE - client
- *pu8AttributeControlBits*: Pointer to an array of **uint8** values, with one element for each attribute in the cluster (see above).
- *psClusterInstance*: Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initialising individual structure fields.
- *psClusterDefinition*: Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the Simple Metering cluster. This parameter can refer to a pre-filled structure called sCLD_SimpleMetering which is provided in the **SimpleMetering.h** file.
- *psCustomDataStructure*: Pointer to structure which contains custom data for the Simple Metering cluster. This structure is used for internal data storage and also contains data relating to a received command/message. No knowledge of the fields of this structure is required.
- *pvEndPointSharedStructPtr*: Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_SimpleMetering which defines the attributes of Simple Metering cluster. The function will initialize the attributes with default values.

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eSE_ReadMeterAttributes

```
teZCL_Status eSE_ReadMeterAttributes(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used to send a 'read attributes' request to the Simple Metering cluster on a remote endpoint. The function requests all Simple Metering attributes to be read - alternatively, the function **eZCL_SendReadAttributesRequest()** can be used if only specific attributes are required. Note that read access to cluster attributes on the remote node (server) and local node (client) must be enabled at compile-time, as described in Section 1.3.

You must specify the endpoint on the local node from which the request is to be sent. This is also used to identify the instance of the local shared device structure which holds the relevant attributes. The obtained attribute values are written to this shared structure by the function.

You must also specify the address of the destination node and the destination endpoint number. It is possible to use this function to send a request to bound endpoints or to a group of endpoints on remote nodes - in the latter case, a group address must be specified. Note that when sending requests to multiple endpoints through a single call to this function, multiple responses will subsequently be received from the remote endpoints.

You are also required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Following the first response to this function call, your application should call the function **eSE_HandleReadAttributesResponse()** to ensure that all the Simple Metering attributes are received from the remote endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which the request is sent
- *u8DestinationEndPointId*: Number of the remote endpoint to which the request is sent. Note that this parameter is ignored when sending to address types E_ZCL_AM_BOUND and E_ZCL_AM_GROUP
- *psDestinationAddress*: Pointer to a structure containing the address of the remote node to which the request is sent
- *pu8TransactionSequenceNumber*: Pointer to a location to store the Transaction Sequence Number (TSN) of the request

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_CLUSTER_ID_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_ATTRIBUTE_WO
- E_ZCL_ERR_ATTRIBUTES_ACCESS
- E_ZCL_ERR_ATTRIBUTE_NOT_FOUND
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_PARAMETER_RANGE

Parent topic: Functions

eSE_HandleReadMeterAttributesResponse

```
teSE_Status eSE_HandleReadAttributesResponse(
    tsZCL_CallBackEvent *psEvent,
    uint8 *puTransactionSequenceNumber);
```

Description This function should be called after **eSE_ReadMeterAttributes()**. The function examines the response to a 'read attributes' request for the Simple Metering cluster and determines whether the response is complete - that is, whether it contains all the Simple Metering attributes (the response may be incomplete if the returned data is too large to fit into a single APDU). If the response is not complete, the function will re-send 'read attributes' requests until all attribute values have been obtained. Any further attribute values obtained are written to the local shared device structure containing the attributes.

This function call should normally be included in the user-defined callback function that is invoked when the event E_ZCL_CBET_READ_ATTRIBUTES_RESPONSE is generated. This is the callback function which is specified when the (requesting) endpoint is registered using the appropriate endpoint registration function. The callback function must pass the generated event into **eSE_HandleReadAttributesResponse()**.

You are also required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request/response.

Parameters

- *psEvent*: Pointer to the generated event E_ZCL_CBET_READ_ATTRIBUTES_RESPONSE
- *pu8TransactionSequenceNumber*: Pointer to a location to store the Transaction Sequence Number (TSN) of the request/response

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_CLUSTER_ID_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_ATTRIBUTE_WO
- E_ZCL_ERR_ATTRIBUTES_ACCESS
- E_ZCL_ERR_ATTRIBUTE_NOT_FOUND
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_PARAMETER_RANGE

Parent topic: Functions

eSM_ServerRequestMirrorCommand

```
teZCL_Status eSM_ServerRequestMirrorCommand(
    uint8 u8SourceEndpoint,
    uint8 u8DestinationEndpoint,
    tsZCL_Address *psDestinationAddress);
```

Description This function can be used by a Metering Device to request a mirror on the ESP, for the central storage of its metering data. A mirror is useful for a Metering Device which sleeps, in order to allow access to its metering data while the device is sleeping.

The function sends an 'Add Mirror' request to the ESP. The address of the ESP device must be specified as well as the endpoint that will receive and process the request - this is the main endpoint on which the ESP is registered on the Co-ordinator. If successful, the request will result in the allocation of a mirror endpoint (on the ESP) to the Metering Device.

Note: Before using this function to send an 'Add Mirror' request, the Metering Device application should check whether the ESP is currently accepting these requests by calling the function **eZCL_SendReadAttributesRequest()** to obtain the value of the u8PhysicalEnvironment attribute of the Basic cluster on the ESP. This attribute value will be non-zero if 'Add Mirror' requests are being accepted.

eSM_ServerRequestMirrorCommand() is a non-blocking function and so returns immediately after the request has been sent. The application must then wait for a response, indicated by the event E_CLD_SM_SERVER_RECEIVED_COMMAND containing the command E_CLD_SM_REQUEST_MIRROR_RESPONSE. If a mirror was successfully created, the number of the allocated mirror endpoint on the ESP is included in the event.

Mirroring and mirror set-up are fully described in Section 42.5.

Parameters

- *u8SourceEndpoint*: Number of local endpoint through which request is sent
- *u8DestinationEndpoint*: Number of ESP endpoint to which request is sent (main endpoint of ESP)
- *psDestinationAddress*: Pointer to a structure containing the address of the ESP device (to which the request is sent)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_ZTRANSMIT_FAIL
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_CLUSTER_ID_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_EP_RANGE

Parent topic: Functions

eSM_ServerRemoveMirrorCommand

```
teZCL_Status eSM_ServerRemoveMirrorCommand(
    uint8 u8SourceEndpoint,
    uint8 u8DestinationEndpoint,
    tsZCL_Address *psDestinationAddress);
```

Description This function can be used on a Metering Device to request the removal of the corresponding mirror on the ESP. The function should only be used to remove a mirror that has been previously set up by the Metering Device application using the function **eSM_ServerRequestMirrorCommand()**.

The function sends a 'Remove Mirror' request to the ESP. The address of the ESP must be specified as well as the endpoint number of the mirror to be removed.

This is a non-blocking function and so returns immediately after the request has been sent. The application must then wait for a response.

- If the request was successful, a response will be received from the ESP resulting in the generation of the event E_CLD_SM_SERVER_RECEIVED_COMMAND containing the command E_CLD_SM_MIRROR_REMOVED
- If the request was unsuccessful, a ZCL default response will be received from the ESP to indicate that the request was not authorised (E_ZCL_CMDS_NOT_AUTHORIZED)

Mirror removal is fully described in Section 42.5.5.

Parameters

- *u8SourceEndpoint*: Number of local endpoint through which request is sent
- *u8DestinationEndpoint*: Number of ESP endpoint which contains the mirror to be removed
- *psDestinationAddress*: Pointer to a structure containing the address of the ESP device (to which the request is sent)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_ZTRANSMIT_FAIL
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_CLUSTER_ID_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_EP_RANGE

Parent topic: Functions

eSM_CreateMirror

```
teSM_Status eSM_CreateMirror(
    uint8 u8MirrorEndpoint,
    uint64 u64RemoteIeeeAddress);
```

Description This function can be used on the mirroring server (ESP) to create a mirror with the specified endpoint number for the Metering Device with the specified IEEE address. The endpoint number must be within the valid range for mirror endpoints on the ESP.

An error will be returned if there is no free mirror endpoint on which to create a mirror.

The function is normally used by an ESP application following a device reset, in order to recreate mirrors that were lost during the reset. This recovery assumes that the relevant IEEE addresses (for Metering Devices) associated with the mirror endpoints can be retrieved from non-volatile memory, where they were saved before the reset.

Parameters

- *u8MirrorEndpoint*: Number of endpoint on which mirror will be created (must be within valid range for mirror endpoints)
- *u64RemoteIeeeAddress*: IEEE address of Metering Device to be mirrored

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_RANGE
- E_CLD_SM_STATUS_EP_NOT_AVAILABLE

Parent topic: Functions

eSM_RemoveMirror

```
teSM_Status eSM_RemoveMirror(
    uint8 u8MirrorEndpoint,
    uint64 u64RemoteIeeeAddress);
```

Description This function can be used on the mirroring server (ESP) to remove the mirror with the specified endpoint number for the Metering Device with the specified IEEE address. The endpoint will then become free to be re-allocated for another mirror.

An error will be returned if the specified mirror endpoint cannot be found.

Parameters

- *u8MirrorEndpoint*: Number of endpoint which hosts mirror to be removed (must be within valid range for mirror endpoints)
- *u64RemoteIeeeAddress*: : IEEE address of mirrored Metering Device

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_PARAMETER_RANGE
- E_CLD_SM_STATUS_EP_NOT_AVAILABLE
- E_ZCL_FAIL

Parent topic: Functions

eSM_GetFreeMirrorEndPoint

```
teZCL_Status eSM_GetFreeMirrorEndPoint(
    uint16 *pu16FreeEP);
```

Description This function can be used on the mirroring server (ESP) to obtain the number of the next available mirror endpoint. If there are no free mirror endpoints, the function sets the returned endpoint number to 0xFFFF.

The function is normally used in the ESP callback function to check the availability of mirror endpoints before updating the u8PhysicalEnvironment attribute of the Basic cluster (this attribute is set to zero if no more mirror endpoints are available).

Use of this function is described in Section 42.5.1.

Parameters

- *pu16FreeEP*: Pointer to location to receive next free endpoint number

Returns

- E_ZCL_SUCCESS

Parent topic: Functions

eSM_IsMirrorSourceAddressValid

```
eSM_IsMirrorSourceAddressValid(
tsZCL_ReportAttributeMirror *psZCL_ReportAttributeMirror);
```

Description This function can be used on the ESP to handle mirroring data reported from a Metering Device. If mirroring is enabled, the function should be included in the callback function on the ESP.

When the ESP receives mirroring data from a Metering Device, the event E_ZCL_CBET_ATTRIBUTE_REPORT_MIRROR is generated, causing the callback function to be invoked. The callback function should call this function to deal with the event.

The function first checks that the data comes from a Metering Device which has a mirror on the ESP (the source IEEE address of the data is used for this check) and then updates the event status accordingly:

```
sZCL_CallBackEvent.uMessage.sReportAttributeMirror.eStatus
```

If the source device is valid then this status is set to E_ZCL_ATTR_REPORT_OK and the metering data is automatically stored on the relevant mirror endpoint. Otherwise, a ZCL default response is returned to the Metering Device to indicate that mirroring is not authorised for this device (E_ZCL_CMDS_NOT_AUTHORIZED).

The mirroring of metering data is fully described in Section 42.5.3.

Parameters

- *psZCL_ReportAttributeMirror*: Pointer to sReportAttributeMirror element of the event

Returns

- E_ZCL_SUCCESS

Parent topic: Functions

eSM_ServerUpdateConsumption

```
teZCL_Status eSM_ServerUpdateConsumption(
    uint8 u8SourceEndPointId,
    uint32 u32UtcTime);
```

Description This function can be used on a Simple Metering cluster server (with the 'Get Profile' feature enabled) to add a new entry to the circular buffer used to store historical consumption data. The buffer stores a sequence of entries containing consumption data for consecutive time intervals, identified by their end-times.

Before this function is called, the application must update one or both of the following Simple Metering cluster attributes with the relevant consumption(s) over the last time interval (since the last readings were made):

```
u24CurrentPartialProfileIntervalValueDelivered
u24CurrentPartialProfileIntervalValueReceived
```

An attribute only needs to be updated if the corresponding consumption has been implemented.

The function takes the current time (UTC time) as an input and adds a buffer entry containing the consumption measurements together with the supplied UTC time, which is saved as the end-time of the interval

The entry is stored as a tsSEGetProfile structure, described in Section 42.11.5.

The buffer can contain a limited number of entries, determined at compile-time (see Section 42.12), and operates on a FIFO basis so that a new entry added to a full buffer will over-write the oldest entry.

The function should be called periodically by the application. The period must match the value to which the Simple Metering eProfileIntervalPeriod attribute has been set (see Section 42.2). Standard periods, ranging from 2.5 minutes to one day, are provided as a set of enumerations (see Section 42.10.10).

Parameters

- *u8SourceEndPointId*: Number of local endpoint on which the Simple Metering cluster server operates
- *u32UtcTime*: Current time (as UTC time which can be obtained using **u32ZCL_GetUTCTime()**)

Returns

- E_ZCL_SUCCESS

Parent topic: Functions

eSM_ClientGetProfileCommand

```
teZCL_Status eSM_ClientGetProfileCommand(
    uint8 u8SourceEndpoint,
    uint8 u8DestinationEndpoint,
    tsZCL_Address *psDestinationAddress,
    uint8 u8IntervalChannel,
    uint32 u32EndTime,
    uint8 u8NumberOfPeriods);
```

Description This function can be used on a Simple Metering cluster client (with the 'Get Profile' feature enabled) to send a 'Get Profile' request to the Simple Metering cluster server in order to retrieve historical consumption data.

The server contains a circular buffer which stores a sequence of data entries containing consumption data for consecutive time intervals, identified by their end-times. This function can

request a number of entries from the buffer, containing the consumption data over multiple intervals.

The function parameters include:

- The number of buffer entries (corresponding to consumption intervals) requested
- The most recent end-time for which a buffer entry will be reported - the most recent consumption data will be reported which has an end-time equal to or earlier than this end-time (a specified end-time of zero will result in the most recent consumption data)
- A value indicating whether the units delivered or units received are being requested

This is a non-blocking function and so returns immediately after the request has been sent. The application must then wait for a response, which is accessed using the function **u32SM_GetReceivedProfileData()**.

Parameters

- *u8SourceEndpoint*: Number of local endpoint through which request is sent
- *u8DestinationEndpoint*: Number of endpoint to which request is sent on the destination device
- *psDestinationAddress*: : Pointer to a structure containing the address of the destination device
- *u8IntervalChannel*: Required consumption data - received or delivered:
- E_CLD_SM_CONSUMPTION_RECEIVED
- E_CLD_SM_CONSUMPTION_DELIVERED
- *u32EndTime*: A UTC time representing the most recent interval end-time for which data will be reported (a zero value means report data for the most recent interval)
- *u8NumberOfPeriods*: Number of consumption intervals to be reported

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_ZTRANSMIT_FAIL
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_CLUSTER_ID_RANGE
- E_ZCL_ERR_EP_UNKNOWN
- E_ZCL_ERR_EP_RANGE

Parent topic: Functions

u32SM_GetReceivedProfileData

```
uint32 u32SM_GetReceivedProfileData(
    tsSM_GetProfileResponseCommand
    *psSMGetProfileResponseCommand);
```

Description This function is used on a Simple Metering cluster client to obtain the consumption data received in a 'Get Profile' response. The response is obtained from the Simple Metering cluster server (and previously requested by the client through a call to **eSM_ClientGetProfileCommand()**).

When a 'Get Profile' response from the server arrives, the event E_CLD_SM_CLIENT_RECEIVED_COMMAND containing the command E_CLD_SM_GET_PROFILE_RESPONSE is generated on the client. This response causes the callback function on the device to be invoked (for an IPD, this is the callback function registered through **eSE_RegisterIPDEndPoint()**). The callback function should deal with the response.

This function can be called within the callback function to extract consumption data from the event. It is necessary to provide the function with a pointer to the response within the event. The function returns the data corresponding to one consumption interval on each call. Therefore, if the response contains data for multiple intervals, the function must be called multiple times to extract all of this data. The number of intervals contained in the response is also included in the response:

```
sSMCallBackMessage.uMessage.sGetProfileResponseCommand.u8NumberOfPeriodsDelivered
```

When there is no more data to be extracted from the event, the function returns 0xFFFFFFFF.

Parameters

- *psSMGetProfileResponseCommand*: Pointer to sGetProfileResponseCommand element of the event

Returns

- 32-bit value corresponding to consumption data for one interval

0xFFFFFFFF indicates that there is no more data to be read from the event.

Parent topic:*Simple Metering Cluster*

Return codes The Simple Metering cluster functions use the ZCL return codes, listed in Section 7.2.

Parent topic:*Simple Metering Cluster*

Enumerations

'Attribute ID' Enumerations The following structure contains the enumerations used to identify the attributes of the Simple Metering cluster.

Note: Some of the following enumerations correspond to attributes that are not certifiable in SE 1.1.1 (07-5356-17) or earlier and are for future use (as indicated in the attribute descriptions in Section 42.2).

```
typedef enum PACK
{
    /* Reading information attribute set attribute IDs*/
    E_CLD_SM_ATTR_ID_CURRENT_SUMMATION_DELIVERED     =     0x0000,
    E_CLD_SM_ATTR_ID_CURRENT_SUMMATION_RECEIVED,
    E_CLD_SM_ATTR_ID_CURRENT_MAX_DEMAND_DELIVERED,
```

(continues on next page)

(continued from previous page)

```
    E_CLD_SM_ATTR_ID_CURRENT_MAX_DEMAND_RECEIVED,
    E_CLD_SM_ATTR_ID_DFT_SUMMATION,
    E_CLD_SM_ATTR_ID_DAILY_FREEZE_TIME,
    E_CLD_SM_ATTR_ID_POWER_FACTOR,
    E_CLD_SM_ATTR_ID_READING_SNAPSHOT_TIME,
    E_CLD_SM_ATTR_ID_CURRENT_MAX_DEMAND_DELIVERED_TIME,
    E_CLD_SM_ATTR_ID_CURRENT_MAX_DEMAND_RECEIVED_TIME,
    E_CLD_SM_ATTR_ID_DEFAULT_UPDATE_PERIOD,
    E_CLD_SM_ATTR_ID_FAST_POLL_UPDATE_PERIOD,
    E_CLD_SM_ATTR_ID_CURRENT_BLOCK_PERIOD_CONSUMPTION_DELIVERED,
    E_CLD_SM_ATTR_ID_DAILY_CONSUMPTION_TARGET,

Parent topic: Enumerations

'Meter Status' Enumerations Enumerations for the u8MeterStatus element in the Simple Metering cluster structure tsSE_SimpleMetering are provided as #defines.

The following enumerated masks can be used to set the meter status:

Enumeration	Description
E_CLD_SM_METER_STATUS_CHECK_METER_MASK	Non-fatal problem detected on meter
E_CLD_SM_METER_STATUS_LOW_BATTERY_MASK	Battery level is low
E_CLD_SM_METER_STATUS_TAMPER_DETECT_MASK	Detected tampering with device
E_CLD_SM_METER_STATUS_POWER_FAILURE_MASK	Indicates power failure on device
E_CLD_SM_METER_STATUS_POWER_QUALITY_MASK	Power anomaly detected
E_CLD_SM_METER_STATUS_LEAK_DETECT_MASK	Detected leak (e.g. of gas or water)
E_CLD_SM_METER_STATUS_SERVICE_DISCONNECT_OPEN_	Service to premises disconnected

Parent topic: Enumerations

'Unit of Measure' Enumerations The following enumerations are used to set the teSE_UnitOfMeasure element in the Simple Metering cluster structure tsSE_SimpleMetering. Separate sets of enumerations are provided for binary and BCD (Binary Coded Decimal) representations.

```
typedef enum PACK
{
    /* Binary values */
    E_CLD_SM_UOM_KILO_WATTS                 = 0x00,
    E_CLD_SM_UOM_CUBIC_METER,
    E_CLD_SM_UOM_CUBIC_FEET,
    E_CLD_SM_UOM_100_CUBIC_FEET,            /* ccf & ccf/h */
    E_CLD_SM_UOM_US_GALLON,                 /* USG & USG/h */
    E_CLD_SM_UOM_IMPERIAL_GALLON,           /* IMPG & IMPG/h */
    E_CLD_SM_UOM_BTU,                       /* BTU & BTU/h */
    E_CLD_SM_UOM_LITERS,                    /* Liters & Liters/h */
    E_CLD_SM_UOM_KPA_GAUGE,
    E_CLD_SM_UOM_KPA_ABSOLUTE,
    /* BCD values */
    E_CLD_SM_UOM_KILO_WATTS_BCD             = 0x80,
    E_CLD_SM_UOM_CUBIC_METER_BCD,
    E_CLD_SM_UOM_CUBIC_FEET_BCD,
    E_CLD_SM_UOM_100_CUBIC_FEET_BCD,        /* ccf & ccf/h */
    E_CLD_SM_UOM_US_GALLON_BCD,             /* USG & USG/h */
    E_CLD_SM_UOM_IMPERIAL_GALLON_BCD,       /* IMPG & IMPG/h */
    E_CLD_SM_UOM_BTU_BCD,                   /* BTU & BTU/h */
    E_CLD_SM_UOM_LITERS_BCD,                /* Liters & Liters/h */
    E_CLD_SM_UOM_KPA_GAUGE_BCD,
    E_CLD_SM_UOM_KPA_ABSOLUTE_BCD
} teCLD_SM_UnitOfMeasure;
```

The above enumerations are detailed in the table below.

Enumeration	Description
	Instantaneous
Binary Values	
E_CLD_SM_UOM_KILO_WATTS	kW (kiloWatts)
E_CLD_SM_UOM_CUBIC_METER	m3/h (cubic metres per hour)
E_CLD_SM_UOM_CUBIC_FEET	ft3/h (cubic feet per hour)
E_CLD_SM_UOM_100_CUBIC_FEET	ccf/h (100 cubic feet per hour)
E_CLD_SM_UOM_US_GALLON	US gl/h (US Gallons per hour)
E_CLD_SM_UOM_IMPERIAL_GALLON	Imperial gl/h (Imperial Gallons per hour)
E_CLD_SM_UOM_BTU	BTU/h (British Thermal Units per hour)
E_CLD_SM_UOM_LITERS	l/h (litres per hour)
E_CLD_SM_UOM_KPA_GAUGE	kPA (kiloPascal) gauge
E_CLD_SM_UOM_KPA_ABSOLUTE	kPA (kiloPascal) absolute
BCD Values	
E_CLD_SM_UOM_KILO_WATTS_BCD	kW (kiloWatts)
E_CLD_SM_UOM_CUBIC_METER_BCD	m3/h (cubic metres per hour)
E_CLD_SM_UOM_CUBIC_FEET_BCD	ft3/h (cubic feet per hour)
E_CLD_SM_UOM_100_CUBIC_FEET_BCD	ccf/h (100 cubic feet per hour)
E_CLD_SM_UOM_US_GALLON_BCD	US gl/h (US Gallons per hour)
E_CLD_SM_UOM_IMPERIAL_GALLON_BCD	Imperial gl/h (Imperial Gallons per hour)
E_CLD_SM_UOM_BTU_BCD	BTU/h (British Thermal Units per hour)
E_CLD_SM_UOM_LITERS_BCD	l/h (litres per hour)
E_CLD_SM_UOM_KPA_GAUGE_BCD	kPA (kiloPascal) gauge
E_CLD_SM_UOM_KPA_ABSOLUTE_BCD	kPA (kiloPascal) absolute

Parent topic: Enumerations

'Summation Formatting' Enumerations Enumerations for use with the u8SummationFormatting element in the Simple Metering cluster structure u8SummationFormatting are provided as #defines. The enumerations allow the following formatting information to be extracted from the u8SummationFormatting bitmap:

Enumeration	Description
E_CLD_SM_FORMATTING_DIGITS_TO_RI	Position of least significant bit of bit-field indicating number of digits to right of decimal point
E_CLD_SM_FORMATTING_DIGITS_TO_RI	Number of bits in bit-field indicating number of digits to right of decimal point
E_CLD_SM_FORMATTING_DIGITS_TO_RI	Bit-mask used to extract number of digits to right of decimal point
E_CLD_SM_FORMATTING_DIGITS_TO_LE	Position of least significant bit of bit-field indicating number of digits to left of decimal point
E_CLD_SM_FORMATTING_DIGITS_TO_LE	Number of bits in bit-field indicating number of digits to left of decimal point
E_CLD_SM_FORMATTING_DIGITS_TO_LE	Bit-mask used to extract number of digits to left of decimal point
E_CLD_SM_FORMATTING_SUPPRESS_LE	Bit-mask used to extract bit indicating whether lead-ing zeros will be suppressed

The following are examples of the use of the above enumerations.

Extracting the number of digits to the right of the decimal point:

```
u8BitsToRight = (u8SummationFormatting & E_CLD_SM_FORMATTING_DIGITS_TO_RIGHT_OF_
↪DP_MASK)
>> E_CLD_SM_FORMATTING_DIGITS_TO_RIGHT_OF_DP_LS_BIT
```

Extracting the number of digits to the left of the decimal point:

```
u8BitsToLeft = (u8SummationFormatting & E_CLD_SM_FORMATTING_DIGITS_TO_LEFT_OF_DP_
↪MASK)
>> E_CLD_SM_FORMATTING_DIGITS_TO_LEFT_OF_DP_LS_BIT
```

Determining whether leading zeros will be suppressed:

```
bSuppressZeros = !((u8SummationFormatting & E_CLD_SM_FORMATTING_SUPPRESS_LEADING_
↪ZEROS_BIT) == 0)
```

Parent topic: Enumerations

'Supply Direction' Enumerations The following enumerations are used to indicate the direction of supply.

```
typedef enum PACK
{
    E_CLD_SM_CONSUMPTION_DELIVERED,
    E_CLD_SM_CONSUMPTION_RECEIVED
}teSM_IntervalChannel;
```

The above enumerations are detailed in the table below.

Enumeration	Description
E_CLD_SM_CONSUMPT	Specifies that the supply is from the customer to the utility company (in cases where the customer generates their own supply)
E_CLD_SM_CONSUMPT	Specifies that the supply is from the utility company to the customer

Parent topic: Enumerations

'Metering Device Type' Enumerations The following enumerations are used to set the eMeteringDeviceType element in the Simple Metering cluster structure tsSE_SimpleMetering.

```
typedef enum PACK
{
    E_CLD_SM_MDT_ELECTRIC                = 0x00,
    E_CLD_SM_MDT_GAS,
    E_CLD_SM_MDT_WATER,
    E_CLD_SM_MDT_THERMAL,                /* Deprecated */
    E_CLD_SM_MDT_PRESSURE,
    E_CLD_SM_MDT_HEAT,
    E_CLD_SM_MDT_COOLING,
    E_CLD_SM_MDT_GAS_MIRRORED            = 0x80,
    E_CLD_SM_MDT_WATER_MIRRORED,
    E_CLD_SM_MDT_THERMAL_MIRRORED,
    E_CLD_SM_MDT_PRESSURE_MIRRORED,
```

(continues on next page)

(continued from previous page)

```
    E_CLD_SM_MDT_HEAT_MIRRORED,
    E_CLD_SM_MDT_COOLING_MIRRORED,
} teCLD_SM_MeteringDeviceType;
```

The above enumerations are detailed in the table below.

Enumeration	Description
E_CLD_SM_MDT_ELECTRIC	Electric Meter
E_CLD_SM_MDT_GAS	Gas Meter
E_CLD_SM_MDT_WATER	Water Meter
E_CLD_SM_MDT_THERMAL	Thermal Meter (deprecated)
E_CLD_SM_MDT_PRESSURE	Pressure Meter
E_CLD_SM_MDT_HEAT	Heat Meter
E_CLD_SM_MDT_COOLING	Cooling Meter
E_CLD_SM_MDT_GAS_MIRRORED	Mirrored Gas Meter
E_CLD_SM_MDT_WATER_MIRRORED	Mirrored Water Meter
E_CLD_SM_MDT_THERMAL_MIRRORED	Mirrored Thermal Meter (deprecated)
E_CLD_SM_MDT_PRESSURE_MIRRORED	Mirrored Pressure Meter
E_CLD_SM_MDT_HEAT_MIRRORED	Mirrored Heat Meter
E_CLD_SM_MDT_COOLING_MIRRORED	Mirrored Cooling Meter

Parent topic: Enumerations

'Simple Metering Event' Enumerations The event types generated by the Simple Metering cluster are enumerated in the teSM_CallBackEventType structure below:

```
typedef enum PACK
{
        E_CLD_SM_CLIENT_RECEIVED_COMMAND,
        E_CLD_SM_SERVER_RECEIVED_COMMAND,
        E_CLD_SM_FAST_POLLING_TIMER_EXPIRED
}teSM_CallBackEventType;
```

The above event types are described in the table below.

Event Type Enumeration	Description
E_CLD_SM_CLIENT_RECEIVE	Generated on a cluster client when a command is received from the server
E_CLD_SM_SERVER_RECEIVE	Generated on the cluster server when a command is received from a client
E_CLD_SM_FAST_POLLING_T	Generated on the cluster server when the end-time of a fast polling episode is reached (*for future use*)

Parent topic: Enumerations

'Server Command' Enumerations The comands issued by a Simple Metering cluster server and received by a client are enumerated in the teSM_ClusterServerCommands structure below:

```
typedef enum PACK
{
    E_CLD_SM_GET_PROFILE_RESPONSE,
```

(continues on next page)

(continued from previous page)

```
    E_CLD_SM_REQUEST_MIRROR,
    E_CLD_SM_REMOVE_MIRROR,
    E_CLD_SM_REQUEST_FAST_POLL_MODE_RESPONSE,
    E_CLD_SM_CLIENT_ERROR
}teSM_ClusterServerCommands;
```

Command Enumeration	Description
E_CLD_SM_GET_PROFILI	Response to 'Get Profile' request - content of response is contained in the structure tsS-M_GetProfileResponseCommand in the event (see Section 42.11.9)
E_CLD_SM_REQUEST_MI	An 'Add Mirror' request
E_CLD_SM_REMOVE_MII	A 'Remove Mirror' request
E_CLD_SM_REQUEST_FA RESPONSE	Response to 'Fast Polling' request (*for future use*)
E_CLD_SM_CLIENT_ERR	Error condition - content of error is contained in the structure tsSM_Error in the event (see Section 42.11.10)

Parent topic: Enumerations

'Client Command' Enumerations The comands issued by a Simple Metering cluster client and received by the server are enumerated in the teSM_ClusterClientCommands structure below:

```
typedef enum PACK
{
    E_CLD_SM_GET_PROFILE,
    E_CLD_SM_REQUEST_MIRROR_RESPONSE,
    E_CLD_SM_MIRROR_REMOVED,
    E_CLD_SM_REQUEST_FAST_POLL_MODE,
    E_CLD_SM_SERVER_ERROR
}teSM_ClusterClientCommands;
```

Command Enumeration	Description
E_CLD_SM_GET_PR	A 'Get Profile' request - content of request is contained in the structure tsSM_GetProfile-RequestCommand in the event (see Section42.11.8)
E_CLD_SM_REQUES	Response to 'Add Mirror' request - content of response is contained in the structure tsS-M_RequestMirrorResponseCommand in the event (see Section 42.11.6)
E_CLD_SM_MIRROR	Response to 'Remove Mirror' request - content of response is contained in the structure tsS-M_MirrorRemovedResponseCommand in the event (see Section 42.11.7)
E_CLD_SM_REQUES	A 'Fast Polling' request (*for future use*)
E_CLD_SM_SERVER_	Error condition - content of error is contained in the structure tsSM_Error in the event (see Section 42.11.10)

Parent topic: Enumerations

'Consumption Interval' Enumerations The following enumerations define the possible time-intervals for the consumption data captured in the 'Get Profile' feature.

```
typedef enum PACK
{
   E_CLD_SM_TIME_FRAME_DAILY,
   E_CLD_SM_TIME_FRAME_60MINS,
   E_CLD_SM_TIME_FRAME_30MINS,
   E_CLD_SM_TIME_FRAME_15MINS,
   E_CLD_SM_TIME_FRAME_10MINS,
   E_CLD_SM_TIME_FRAME_7_5MINS,
   E_CLD_SM_TIME_FRAME_5MINS,
   E_CLD_SM_TIME_FRAME_2_5MINS
}teSM_TimeFrame;
```

Time Frame Enumeration	Time Interval
E_CLD_SM_TIME_FRAME_DAILY	One day
E_CLD_SM_TIME_FRAME_60MINS	60 minutes
E_CLD_SM_TIME_FRAME_30MINS	30 minutes
E_CLD_SM_TIME_FRAME_15MINS	15 minutes
E_CLD_SM_TIME_FRAME_10MINS	10 minutes
E_CLD_SM_TIME_FRAME_7_5MINS	7.5 minutes
E_CLD_SM_TIME_FRAME_5MINS	5 minutes
E_CLD_SM_TIME_FRAME_2_5MINS	2.5 minutes

Parent topic: Enumerations

'Simple Metering Status' Enumerations The following enumerations are used to report status in the Simple Metering cluster.

```
typedef enum PACK
{
   E_CLD_SM_STATUS_SUCCESS,
   E_CLD_SM_STATUS_UNDEFINED_INTERVAL_CHANNEL,
   E_CLD_SM_STATUS_INTERVAL_NOT_SUPPORTED,
   E_CLD_SM_STATUS_INVALID_END_TIME,
   E_CLD_SM_STATUS_MORE_PERIODS_REQUESTED_THAN_SUPPORTED,
   E_CLD_SM_STATUS_NO_INTERVALS_AVAILABLE_FOR_REQUESTED_TIME,
   E_CLD_SM_STATUS_EP_NOT_AVAILABLE
}teSM_Status;
```

Status Enumeration	Description
E_CLD_SM_STATUS_SUCCESS	Success
E_CLD_SM_STATUS_UNDEFINED_INTI	Undefined eIntervalChannel value speci-fied in 'Get Profile' request (see Section42.11.8)
E_CLD_SM_STATUS_INTERVAL_NOT_S	Unsupported consumption data specifed through eIntervalChannel in 'Get Profile' request (see Section 42.11.8)
E_CLD_SM_STATUS_INVALID_END_TI	Invalid end-time specified in 'Get Profile' request (Section 42.11.8)
E_CLD_SM_STATUS_MORE_PERIODS_	More periods specified in 'Get Profile' request than can be returned
E_CLD_SM_STATUS_NO_INTERVALS_A	No intervals available for the end-time specified in 'Get Profile' request
E_CLD_SM_STATUS_EP_NOT_AVAILAE	Specified endpoint not available

Structures

tsSM_CallBackMessage For a Simple Metering event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsSM_CallBackMessage structure which contains the Simple Metering parameters:

```
typedef struct
{
    teSM_CallBackEventType eEventType;
     uint8 u8CommandId;
  union
    {
    tsSM_GetProfileResponseCommand     sGetProfileResponseCommand;
    tsSM_RequestFastPollResponseCommand  sRequestFastPollResponseCommand;
    tsSM_GetProfileRequestCommand     sGetProfileCommand;
    tsSM_RequestMirrorResponseCommand    sRequestMirrorResponseCommand;
    tsSM_MirrorRemovedResponseCommand    sMirrorRemovedResponseCommand;
    tsSM_RequestFastPollCommand      sRequestFastPollCommand;
    tsSM_Error           sError;
 }uMessage;
}tsSM_CallBackMessage;
```

where:

- eEventType is the Simple Metering event type from those listed in Section42.10.7
- u8CommandId is the identifier of the type of Simple Metering command received. This field is only valid for the following Simple Metering event types:
  - E_CLD_SM_CLIENT_RECEIVED_COMMAND - enumerated commands are provided, as described in Section 42.10.8
  - E_CLD_SM_SERVER_RECEIVED_COMMAND - enumerated commands are provided, as described in Section 42.10.9
- uMessage is a union containing the command payload in one of the following forms (depending on the command specified in the field u8CommandId):
  - s``GetProfileResponseCommand is a structure containing the payload of a 'Get Profile' response - see Section 42.11.9
  - sRequestFastPollResponseCommand is a structure containing the payload of a 'Fast Polling' response (*for future use*)
  - sGetProfileCommand is a structure containing the payload of a 'Get Profile' request - see Section 42.11.8
  - sRequestMirrorResponseCommand is a structure containing the payload of an 'Add Mirror' response - see Section 42.11.6
  - sMirrorRemovedResponseCommand is a structure containing the payload of an 'Remove Mirror' response - see Section 42.11.7
  - sRequestFastPollCommand is a structure containing the payload of an 'Fast Polling' request (*for future use*)
  - sError is a structure containing the details of an error condition - see Section 42.11.10

Parent topic: Structures

tsSE_Mirror Details of the mirror endpoints on the ESP are kept in an array of structures of the type tsSE_Mirror (one structure per endpoint) within the tsSE_EspMeterDevice structure. The tsSE_Mirror structure is shown and described below.

Note: This structure is only for use by the ZCL and should not be modified by the application.

```
typedef struct
{
        /*Mirrored EndPoint*/
   tsZCL_EndPointDefinition sEndPoint;
   /*Mirror Requester address*/
   uint64       u64SourceAddress;
   /*Mirror cluster instances*/
   tsSE_MirrorClusterInstances        sSEMirrorClusterInstances;
   /*Event Address, Custom callback event, Custom callback message*/
   tsSM_CustomStruct sSMMirrorCustomDataStruct;
}tsSE_Mirror;
```

where:

- sEndPoint is a tsZCL_EndPointDefinition structure which contains details of the endpoint corresponding to the mirror (for details of this structure, refer to Section 6.1.1)
- u64SourceAddress is the 64-bit IEEE address of the Metering Device to which the mirror endpoint is assigned - a zero value indicates that the mirror endpoint is not currently assigned to a device
- sSEMirrorClusterInstances is a tsSE_MirrorClusterInstances structure (see Section 42.11.3) which contains information on the Basic and Simple Metering cluster instances that are associated with the mirror endpoint
- sSMMirrorCustomDataStruct is a tsSM_CustomStruct structure (see Section 42.11.4) which contains data relating to a received command/message for the mirror endpoint

Parent topic: Structures

tsSE_MirrorClusterInstances This structure contains information on the Basic and Simple Metering cluster instances that are associated with a mirror endpoint.

Note: This structure is only for use by the ZCL and should not be modified by the application.

```
typedef struct
{
  /*Basic Cluster Instance*/
        tsZCL_ClusterInstance sBasicCluster;
        /* SM Cluster Instance */
        tsZCL_ClusterInstance sSM_Cluster;
}tsSE_MirrorClusterInstances;
```

where:

- sBasicCluster is a tsZCL_ClusterInstance structure which contains information on the Basic cluster instance associated with a mirror endpoint (for details of this structure, refer to Section 6.1.16)
- sSM_Cluster is a tsZCL_ClusterInstance structure which contains information on the Simple Metering cluster instance associated with a mirror endpoint (for details of this structure, refer to Section 6.1.16)

Parent topic: Structures

tsSM_CustomStruct This structure contains data relating to a command/message for a mirror endpoint.

Note: This structure is only for use by the ZCL software and should not be modified by the application.

```
typedef struct
{
   tsZCL_ReceiveEventAddress  sReceiveEventAddress;
   tsZCL_CallBackEvent        sSMCustomCallBackEvent;
   tsSM_CallBackMessage       sSMCallBackMessage;
} tsSM_CustomStruct;
```

where:

- sReceiveEventAddress is a tsZCL_ReceiveEventAddress structure which contains addressing information relating to a received mirroring command/message
- sSMCustomCallBackEvent is a tsZCL_CallBackEvent structure (see Section 3.1) which contains the event that has been generated as a result of the received command/message
- sSMCallBackMessage is a tsSM_CallBackMessage structure (see Section42.11.1) which contains details of the event and the command/message that caused the event

Parent topic: Structures

tsSEGetProfile This structure is used to store historical consumption data when the 'Get Profile' feature is enabled. The data within the structure corresponds to a single consumption interval.

```
typedef struct
{
        uint32 u32UtcTime;
        zuint24 u24ConsumptionReceived;
        zuint24 u24ConsumptionDelivered;
}tsSEGetProfile;
```

where:

- u32UtcTime is the end-time of the consumption interval (as a UTC time)
- u24ConsumptionReceived is the number of units received from the customer during the interval (for customers who generate and sell their own units)
- u24ConsumptionDelivered is the number of units delivered to the customer during the interval

Parent topic: Structures

tsSM_RequestMirrorResponseCommand This structure contains the details of an 'Add Mirror' response (from a cluster client). It is included in the structure tsSM_CallBackMessage when an E_CLD_SM_SERVER_RECEIVED_COMMAND event containing the command E_CLD_SM_REQUEST_MIRROR_RESPONSE is generated on the cluster server.

```
typedef struct
{
   uint16 u16Endpoint;
}tsSM_RequestMirrorResponseCommand;
```

where u16Endpoint is the number of the endpoint on which the mirror was successfully added or takes the value 0xFFFF if the request failed because no free endpoint was available for the mirror.

Parent topic: Structures

tsSM_MirrorRemovedResponseCommand This structure contains the details of a 'Remove Mirror' response (from a cluster client). It is included in the structure tsSM_CallBackMessage when an E_CLD_SM_SERVER_RECEIVED_COMMAND event containing the command E_CLD_SM_MIRROR_REMOVED is generated on the cluster server.

```
typedef struct
{
    uint16 u16Endpoint;
}tsSM_MirrorRemovedResponseCommand;
```

where u16Endpoint is the number of the endpoint from which the mirror was successfully removed, or takes the value 0xFFFF if the remove request failed.

Parent topic: Structures

tsSM_GetProfileRequestCommand This stucture contains the details of a 'Get Profile' request (from a cluster client). It is included in the structure tsSM_CallBackMessage when an E_CLD_SM_SERVER_RECEIVED_COMMAND event containing the command E_CLD_SM_GET_PROFILE is generated on the cluster server.

```
typedef struct
{
    teSM_IntervalChannel eIntervalChannel;
    uint8 u8NumberOfPeriods;
    uint8 u8SourceEndPoint;
    uint8 u8DestinationEndPoint;
    uint32 u32EndTime;
    tsZCL_Address sSourceAddress;
}tsSM_GetProfileRequestCommand;
```

where:

- eIntervalChannel is a value indicating the required consumption data:
  - E_CLD_SM_CONSUMPTION_RECEIVED - units from customer
  - E_CLD_SM_CONSUMPTION_DELIVERED - units to customer
- u8NumberOfPeriods is the number of consumption intervals for which data is being requested
- u8SourceEndPoint is the number of the source endpoint of the request on the client
- u8DestinationEndPoint is the number of the destination endpoint of the request on the server
- u32EndTime is the end-time for which consumption data is being requested - the most recent consumption data will be reported which has an end-time equal to or earlier than this end-time (a zero value will result in the most recent consumption data)
- sSourceAddress is a structure containing the source address of the request - that is, the address of the requesting client (the structure is described in Section 6.1.4)

Parent topic: Structures

tsSM_GetProfileResponseCommand This stucture contains the details of a 'Get Profile' response (from the cluster server). It is included in the structure tsSM_CallBackMessage when an E_CLD_SM_CLIENT_RECEIVED_COMMAND event containing the command E_CLD_SM_GET_PROFILE_RESPONSE is generated on the cluster server.

```
typedef struct
{
    uint32          u32Endtime;
    teSM_Status     eStatus;
    teSM_TimeFrame u8ProfileIntervalPeriod;
    uint8           u8NumberOfPeriodsDelivered;
    zuint24         *pau24Intervals;
}tsSM_GetProfileResponseCommand;
```

where:

- u32Endtime is the end-time of the consumption data that is being reported, as a UTC time
- eStatus is the status of the response, represented by one of the enumerated values listed in Section 42.10.11
- u8ProfileIntervalPeriod is the time-interval (consumption interval) over which each set of consumption data is collected - one of the standard enumerated values listed in Section 42.10.10
- u8NumberOfPeriodsDelivered is the number of consumption intervals being reported
- pau24Intervals is a pointer to the consumption data being reported

Parent topic: Structures

tsSM_Error This stucture contains the details of an error response (from cluster server or client). It is included in the structure tsSM_CallBackMessage when an E_CLD_SM_SERVER_RECEIVED_COMMAND event is generated containing the command E_CLD_SM_SERVER_ERROR on a client or E_CLD_SM_CLIENT_ERROR on the server.

```
typedef struct
{
    uint8 u8Endpoint;
    uint8 u8Status;
}tsSM_Error;
```

where

- u8Endpoint is the number of the endpoint from which the error is reported
- u8Status is a value representing the nature of the error

Parent topic: Structures

Parent topic:*Simple Metering Cluster*

Compile-time options This section describes the compile-time options that may be enabled in the **zcl_options.h** file of an application that uses the Simple Metering cluster.

The Simple Metering cluster is enabled by defining CLD_SIMPLE_METERING.

Optional Attributes The optional attributes for the Simple Metering cluster are enabled/disabled by defining:

- For optional attributes from 'Reading Information' attribute set:

  - CLD_SM_ATTR_CURRENT_SUMMATION_RECEIVED
  - CLD_SM_ATTR_CURRENT_MAX_DEMAND_DELIVERED
  - CLD_SM_ATTR_CURRENT_MAX_DEMAND_RECEIVED
  - CLD_SM_ATTR_DFT_SUMMATION
  - CLD_SM_ATTR_DAILY_FREEZE_TIME
  - CLD_SM_ATTR_POWER_FACTOR
  - CLD_SM_ATTR_READING_SNAPSHOT_TIME
  - CLD_SM_ATTR_CURRENT_MAX_DEMAND_DELIVERED_TIME
  - CLD_SM_ATTR_CURRENT_MAX_DEMAND_RECEIVED_TIME
- For optional attributes from 'Time-Of-Use (TOU) Information' attribute set:
  - CLD_SM_ATTR_CURRENT_TIER_1_SUMMATION_DELIVERED
  - CLD_SM_ATTR_CURRENT_TIER_1_SUMMATION_RECEIVED
  - CLD_SM_ATTR_CURRENT_TIER_2_SUMMATION_DELIVERED
  - CLD_SM_ATTR_CURRENT_TIER_2_SUMMATION_RECEIVED
  - CLD_SM_ATTR_CURRENT_TIER_3_SUMMATION_DELIVERED
  - CLD_SM_ATTR_CURRENT_TIER_3_SUMMATION_RECEIVED
  - CLD_SM_ATTR_CURRENT_TIER_4_SUMMATION_DELIVERED
  - CLD_SM_ATTR_CURRENT_TIER_4_SUMMATION_RECEIVED
  - CLD_SM_ATTR_CURRENT_TIER_5_SUMMATION_DELIVERED
  - CLD_SM_ATTR_CURRENT_TIER_5_SUMMATION_RECEIVED
  - CLD_SM_ATTR_CURRENT_TIER_6_SUMMATION_DELIVERED
  - CLD_SM_ATTR_CURRENT_TIER_6_SUMMATION_RECEIVED
- For optional attributes from 'Block Information' attribute set:
  - CLD_SM_ATTR_NO_TIER_BLOCK_CURRENT_SUMMATION_DELIVERED_MAX_COUNT (maximum value of 16)
  - CLD_SM_ATTR_NUM_OF_TIERS_CURRENT_SUMMATION_DELIVERED

    (maximum value of 15)
  - CLD_SM_ATTR_NUM_OF_BLOCKS_IN_EACH_TIER_CURRENT_SUMMATION_DELIVERED

    (maximum value of 16)
- For optional attributes from 'Formatting' attribute set:
  - CLD_SM_ATTR_MULTIPLIER
  - CLD_SM_ATTR_DIVISOR
  - CLD_SM_ATTR_DEMAND_FORMATING
  - CLD_SM_ATTR_HISTORICAL_CONSUMPTION_FORMATTING
- For optional attributes from 'ESP Historical Consumption' attribute set:
  - CLD_SM_ATTR_INSTANTANEOUS_DEMAND
  - CLD_SM_ATTR_CURRENT_DAY_CONSUMPTION_DELIVERED
  - CLD_SM_ATTR_CURRENT_DAY_CONSUMPTION_RECEIVED
  - CLD_SM_ATTR_PREVIOUS_DAY_CONSUMPTION_DELIVERED

  - CLD_SM_ATTR_PREVIOUS_DAY_CONSUMPTION_RECEIVED
  - CLD_SM_ATTR_CURRENT_PARTIAL_PROFILE_INTERVAL_START_TIME_DELIVERED
  - CLD_SM_ATTR_CURRENT_PARTIAL_PROFILE_INTERVAL_START_TIME_RECEIVED
  - CLD_SM_ATTR_CURRENT_PARTIAL_PROFILE_INTERVAL_VALUE_DELIVERED
  - CLD_SM_ATTR_CURRENT_PARTIAL_PROFILE_INTERVAL_VALUE_RECEIVED
- For optional attribute from 'Load Profile' attribute set:
  - CLD_SM_ATTR_MAX_NUMBER_OF_PERIODS_DELIVERED
- For optional attributes from 'Supply Limit' attribute set:
  - CLD_SM_ATTR_CURRENT_DEMAND_DELIVERED
  - CLD_SM_ATTR_DEMAND_LIMIT
  - CLD_SM_ATTR_DEMAND_INTEGRATION_PERIOD
  - CLD_SM_ATTR_NUMBER_OF_DEMAND_SUBINTERVALS

Mirroring If the mirroring of metering data is to be enabled (see Section 42.5), the following options must be defined in the **zcl_options.h** file.

On the Simple Metering server on the Metering Device (which will request and report to a mirror on a mirroring server, such as the ESP), there is no need to define anything.

On the Simple Metering client on the mirroring server, such as the ESP, the mirroring option must be enabled by including:

```
#define CLD_SM_SUPPORT_MIRROR
```

In addition, the following defines must be added on the mirroring server (e.g. ESP):

```
#define CLD_BAS_ATTR_PHYSICAL_ENVIRONMENT
```

(flags support for mirroring via a non-zero value of the u8PhysicalEnvironment attribute of the Basic cluster)

```
#define CLD_SM_NUMBER_OF_MIRRORS          <n>
```

(sets the maximum number of mirrors supported on the mirroring server to the value n)

```
#define ZCL_ATTRIBUTE_REPORTING_CLIENT_SUPPORTED
```

(enables support for attribute reporting clients)

The Simple Metering cluster attributes that are supported by mirroring must be defined on the mirroring server (the same set of attributes are mirrored on all endpoints):

- CLD_SM_MIRROR_ATTR_CURRENT_SUMMATION_RECEIVED
- CLD_SM_MIRROR_ATTR_CURRENT_MAX_DEMAND_DELIVERED
- CLD_SM_MIRROR_ATTR_CURRENT_MAX_DEMAND_RECEIVED
- CLD_SM_MIRROR_ATTR_DFT_SUMMATION
- CLD_SM_MIRROR_ATTR_DAILY_FREEZE_TIME
- CLD_SM_MIRROR_ATTR_POWER_FACTOR

- CLD_SM_MIRROR_ATTR_READING_SNAPSHOT_TIME
- CLD_SM_MIRROR_ATTR_CURRENT_MAX_DEMAND_DELIVERED_TIME
- CLD_SM_MIRROR_ATTR_CURRENT_MAX_DEMAND_RECEIVED_TIME
- CLD_SM_MIRROR_ATTR_CURRENT_TIER_1_SUMMATION_DELIVERED
- CLD_SM_MIRROR_ATTR_CURRENT_TIER_1_SUMMATION_RECEIVED
- CLD_SM_MIRROR_ATTR_CURRENT_TIER_2_SUMMATION_DELIVERED
- CLD_SM_MIRROR_ATTR_CURRENT_TIER_2_SUMMATION_RECEIVED
- CLD_SM_MIRROR_ATTR_CURRENT_TIER_3_SUMMATION_DELIVERED
- CLD_SM_MIRROR_ATTR_CURRENT_TIER_3_SUMMATION_RECEIVED
- CLD_SM_MIRROR_ATTR_CURRENT_TIER_4_SUMMATION_DELIVERED
- CLD_SM_MIRROR_ATTR_CURRENT_TIER_4_SUMMATION_RECEIVED
- CLD_SM_MIRROR_ATTR_CURRENT_TIER_5_SUMMATION_DELIVERED
- CLD_SM_MIRROR_ATTR_CURRENT_TIER_5_SUMMATION_RECEIVED
- CLD_SM_MIRROR_ATTR_CURRENT_TIER_6_SUMMATION_DELIVERED
- CLD_SM_MIRROR_ATTR_CURRENT_TIER_6_SUMMATION_RECEIVED
- CLD_SM_MIRROR_ATTR_MULTIPLIER
- CLD_SM_MIRROR_ATTR_DIVISOR
- CLD_SM_MIRROR_ATTR_DEMAND_FORMATING
- CLD_SM_MIRROR_ATTR_HISTORICAL_CONSUMPTION_FORMATTING
- CLD_SM_MIRROR_ATTR_INSTANTANEOUS_DEMAND
- CLD_SM_MIRROR_ATTR_CURRENT_DAY_CONSUMPTION_DELIVERED
- CLD_SM_MIRROR_ATTR_CURRENT_DAY_CONSUMPTION_RECEIVED
- CLD_SM_MIRROR_ATTR_PREVIOUS_DAY_CONSUMPTION_DELIVERED
- CLD_SM_MIRROR_ATTR_PREVIOUS_DAY_CONSUMPTION_RECEIVED
- CLD_SM_MIRROR_ATTR_CURRENT_PARTIAL_PROFILE_INTERVAL_START_TIME_DELIVERED
- CLD_SM_MIRROR_ATTR_CURRENT_PARTIAL_PROFILE_INTERVAL_START_TIME_RECEIVED
- CLD_SM_MIRROR_ATTR_CURRENT_PARTIAL_PROFILE_INTERVAL_VALUE_DELIVERED
- CLD_SM_MIRROR_ATTR_CURRENT_PARTIAL_PROFILE_INTERVAL_VALUE_RECEIVED
- CLD_SM_MIRROR_ATTR_MAX_NUMBER_OF_PERIODS_DELIVERED
- CLD_SM_MIRROR_ATTR_CURRENT_DEMAND_DELIVERED
- CLD_SM_MIRROR_ATTR_DEMAND_LIMIT
- CLD_SM_MIRROR_ATTR_DEMAND_INTEGRATION_PERIOD
- CLD_SM_MIRROR_ATTR_NUMBER_OF_DEMAND_SUBINTERVALS

The Basic cluster attributes that are supported by mirroring must also be defined on the mirroring server (the same set of attributes are mirrored on all endpoints), from the following:

- CLD_BAS_MIRROR_ATTR_APPLICATION_VERSION
- CLD_BAS_MIRROR_ATTR_STACK_VERSION
- CLD_BAS_MIRROR_ATTR_HARDWARE_VERSION
- CLD_BAS_MIRROR_ATTR_MANUFACTURER_NAME

- CLD_BAS_MIRROR_ATTR_MODEL_IDENTIFIER
- CLD_BAS_MIRROR_ATTR_DATE_CODE
- CLD_BAS_MIRROR_ATTR_LOCATION_DESCRIPTION
- CLD_BAS_MIRROR_ATTR_PHYSICAL_ENVIRONMENT
- CLD_BAS_MIRROR_ATTR_DEVICE_ENABLED
- CLD_BAS_MIRROR_ATTR_ALARM_MASK
- CLD_BAS_MIRROR_ATTR_DISABLE_LOCAL_CONFIG

Get Profile If the 'Get Profile' feature is to be used (see Section 42.6), the following options must be defined in the **zcl_options.h** file.

The 'Get Profile' option must be enabled on the server and clients by including:

```
#define CLD_SM_SUPPORT_GET_PROFILE
```

Then, the following must be included on the server (only):

```
#ifdef CLD_SM_SUPPORT_GET_PROFILE
#define     CLD_SM_GETPROFILE_MAX_NO_INTERVALS      <n>
#endif
```

where <n> is the maximum number of consumption intervals to be held on the server (and therefore determines the amount of memory to be reserved for the circular buffer that is used to store the data for these consumption intervals).

Parent topic:*Simple Metering Cluster*

Part X: Commissioning Clusters This part comprises two chapters:

- *Chapter 43* details the **Commissioning** cluster
- *Chapter 44* details the **Touchlink Commissioning** cluster

Commissioning Cluster This chapter details the Commissioning cluster which is defined in the ZCL and is a optional cluster for all ZigBee devices.

The Commissioning cluster has a Cluster ID of 0x0015.

Overview The Commissioning cluster is used for commissioning the ZigBee stack on a device during network installation and defining the device behaviour with respect to the ZigBee network (it does not affect applications operating on the devices).

- The Commissioning cluster server must be implemented on a device that is to be commissioned into a network.
- The Commissioning cluster client must be implemented on a device that can initiate the commissioning of another device into a network - for example, on a commissioning tool.

This optional cluster is enabled by defining CLD_COMMISSIONING in the **zcl_options.h** file. The inclusion of the client or server software must also be pre-defined in the application's compile-time options (in addition, if the cluster is to reside on a custom endpoint then the role of client or server must also be specified when creating the cluster instance). The compile-time options for the Commissioning cluster are fully detailed in Section 43.10.

Only server attributes are supported and all are optional - the required attributes must be enabled in the compile-time options. The information that can potentially be stored in the Commissioning cluster is organised into the following attribute sets: Start-up Parameters, Join Parameters, End Device Parameters, Concentrator Parameters.

Note: The attribute values are set by the application but the application must ensure that these values are synchronized with the settings and NIB values for the ZigBee PRO stack.

The Commissioning cluster also provides optional commands, which can be enabled in the compile-time options.

Parent topic:*Commissioning Cluster*

Commissioning Cluster structure and attributes The Commissioning cluster has only server attributes that are contained in the following tsCLD_Commissioning structure, organised as a set of structures containing the Commissioning cluster attribute sets:

```
typedef struct
{
#ifdef COMMISSIONING_SERVER
/* Start- attribute setup Parameters attribute set */
    tsCLD_StartupParameters          sStartupParameters;
/* Join Parameters attribute set */
    tsCLD_JoinParameters             sJoinParameters;
/* End Device Parameters attribute set */
    tsCLD_EndDeviceParameters        sEndDeviceParameters;
/* Concentrator Parameters attribute set */
    tsCLD_ConcentratorParameters     sConcentratorParameters;
#endif
    zuint16        u16ClusterRevision;
} tsCLD_Commissioning;
```

where:

```
sStartupParameters is a structure containing the attributes of the Start-up Parameters attribute set -
↪ this structure and the associated attributes are detailed in [Section 43.2.1](start-up_parameters_tscld_
↪startupparameters.md#id_d22b5600-7fda-403a-90c7-d433548a4983)
sJoinParameters is a structure containing the attributes of the Join Parameters attribute set -
↪ this structure and the associated attributes are detailed in [Section 43.2.2](join_parameters_tscld_
↪joinparameters.md#id_02f93815-3ce8-498e-a271-cd3675dc7015)
sEndDeviceParameters is a structure containing the attributes of the End Device Parameters attribute set -
↪ this structure and the associated attributes are detailed in [Section 43.2.3](end_device_parameters_tscld_
↪enddeviceparameters.md#id_a29fedbf-ef44-458b-88af-f134a455d4c0)
sConcentratorParameters is a structure containing the attributes of the Concentrator Parameters attribute set -
↪ this structure and the associated attributes are detailed in [Section 43.2.4](concentrator_parameters_tscld_
↪concentratorparamete.md#id_3713b9e8-5da6-4db8-b678-617069de5091)
u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specifica-
tion on which this cluster instance is based. The cluster specification in the ZCL r6 corresponds to a cluster re-
vision of 1. The value is incremented by one for each subsequent revision of the cluster specification. This at-
tribute is also described in [Section 2.4](../../ZCL_fundamentals/topics/global_attributes.md#id_8f80e769-
↪8ccd-4b4f-8609-579f4457d527).
```

Note: Memory is allocated at compile-time for all the Commissioning cluster attributes.

Start-up Parameters (tsCLD_StartupParameters) The tsCLD_StartupParameters structure below contains the attributes of the Start-up Parameters attribute set:

```
typedef struct
{
#ifdef    CLD_COMMISSIONING_ATTR_SHORT_ADDRESS
    uint16              u16ShortAddress;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_EXTENED_PAN_ID
    zieeeaddress        u64ExtPanId;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_PAN_ID
    uint16              u16PANId;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_CHANNEL_MASK
    zbmap32             u32ChannelMask;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_PROTOCOL_VERSION
    uint8               u8ProtocolVersion;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_STACK_PROFILE
    uint8               u8StackProfile;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_START_UP_CONTROL
    zenum8              e8StartUpControl;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_TC_ADDR
    zieeeaddress        u64TcAddr;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_TC_MASTER_KEY
    tsZCL_Key           sTcMasterKey;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_NWK_KEY
    tsZCL_Key           sNwkKey;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_USE_INSECURE_JOIN
    bool_t              bUseInsecureJoin;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_PRE_CONFIG_LINK_KEY
    tsZCL_Key           sPreConfigLinkKey;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_NWK_KEY_SEQ_NO
    uint8               u8NwkKeySeqNo;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_NWK_KEY_TYPE
    zenum8              e8NwkKeyType;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_NWK_MANAGER_ADDR
    uint16              u16NwkManagerAddr;
#endif
} tsCLD_StartupParameters;
```

where:

- u``16ShortAddress is the intended 16-bit network address of the device (which will be used provided that the address is not to be obtained from the parent - that is, on the Co-ordinator or on other ZigBee PRO devices for which e8StartUpControl is set to 0x00).
- u64ExtPanId is the 64-bit Extended PAN ID of the network which the device should join (the special value of 0xFFFFFFFF can be used to specify no particular network).
- u16PANId is the 16-bit PAN ID of the network which the device should join (which will be used provided that the PAN ID is not to be obtained from the parent - that is, on the Co-ordinator or on other ZigBee PRO devices for which e8StartUpControl is set to 0x00).
- u32ChannelMask is a 32-bit bitmap representing an IEEE 802.15.4 channel mask which in-

dicates the set of radio channels that the device should scan as part of the network join or formation process.

- u8ProtocolVersion is used to indicate the ZigBee protocol version that the device is to support (only needed if the device potentially supports multiple versions).
- u8StackProfile is used to indicate the stack profile to be implemented on the device - the possible values are 0x01 for ZigBee Stack profile and 0x02 for ZigBee PRO Stack profile.
- e8StartUpControl is an enumeration which is used to indicate the start-up mode of the device (e.g. device should form a network with the specified Extended PAN ID) and therefore determines how certain other attributes will be used. For further information on how this attribute is used, refer to the ZCL Specification.
- u64TcAddr is the 64-bit IEEE/MAC address of the Trust Centre node for the network with the specified Extended PAN ID (this is needed if security is to be implemented).
- sTcMasterKey is the master key to be used during key establishment with the specified Trust Centre (this is needed if security is to be implemented). The default is a 128-bit zero value indicating that the key is unspecified.
- sNwkKey is the network key to be used when communicating within the network with the specified Extended PAN ID (this is needed if security is to be implemented). The default is a 128-bit zero value indicating that the key is unspecified.
- bUseInsecureJoin is a Boolean flag which, when set to TRUE, allows an unsecured join as a fall-back (even if security is enabled).
- sPreConfigLinkKey is the pre-configured link key between the device and the Trust Centre (this is needed if security is to be implemented). The default is a 128-bit zero value indicating that the key is unspecified.
- u8NwkKeySeqNo is the 8-bit sequence number for the network key. The default value is 0x00.
- e8NwkKeyType is the type of the network key. The default value is 0x01 when u8StackProfile is 0x01 and 0x05 when u8StackProfile is 0x02.
- u16NwkManagerAddr is the 16-bit network address of the Network Manager. The default value is 0x0000, indicating that the Network Manager is the ZigBee Co-ordinator.

Parent topic: Commissioning Cluster structure and attributes

Join Parameters (tsCLD_JoinParameters) The tsCLD_JoinParameters structure below contains the attributes of the Join Parameters attribute set:

```
typedef struct
{
#ifdef    CLD_COMMISSIONING_ATTR_SCAN_ATTEMPTS
   uint8        u8ScanAttempts;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_TIME_BW_SCANS
   uint16       u16TimeBwScans;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_REJOIN_INTERVAL
   uint16       u16RejoinInterval;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_MAX_REJOIN_INTERVAL
   uint16       u16MaxRejoinInterval;
#endif
} tsCLD_JoinParameters;
```

where:

- u8ScanAttempts is the number of scan attempts to make before selecting a parent to join. The default value is 0x05.
- u16TimeBwScans is the time-interval, in milliseconds, between consecutive scan attempts. The default value is 0x64.
- u16RejoinInterval is the time-interval, in seconds, between consecutive attempts to rejoin the network for an End Device which has lost its network connection. The default value is 0x3C.
- u16MaxRejoinInterval is an upper limit, in seconds, on the value of the u16RejoinInterval attribute. The default value is 0x0E10.

Parent topic: Commissioning Cluster structure and attributes

End Device Parameters (tsCLD_EndDeviceParameters) The tsCLD_EndDeviceParameters structure below contains the attributes of the End Device Parameters attribute set:

```
typedef struct
{
#ifdef    CLD_COMMISSIONING_ATTR_INDIRECT_POLL_RATE
   uint16         u16IndirectPollRate;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_PARENT_RETRY_THRSHLD
   uint8          u8ParentRetryThreshold;
#endif
} tsCLD_EndDeviceParameters;
```

where:

- u16IndirectPollRate is the time-interval, in milliseconds, between consecutive polls from an End Device which polls its parent while awake (an End Device with a receiver that is inactive while sleeping).
- u8ParentRetryThreshold is the number of times that an End Device should attempt to re-contact its parent before initiating the rejoin process.

Parent topic: Commissioning Cluster structure and attributes

Concentrator Parameters (tsCLD_ConcentratorParameters) The sCLD_ConcentratorParameters structure below contains the attributes of the Concentrator Parameters attribute set:

```
typedef struct
{
#ifdef    CLD_COMMISSIONING_ATTR_CONCENTRATOR_FLAG
   bool_t         bConcentratorFlag;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_CONCENTRATOR_RADIUS
   uint8          u8ConcentratorRadius;
#endif
#ifdef    CLD_COMMISSIONING_ATTR_CONCENTRATOR_DISCVRY_TIME
   uint8          u8ConcentratorDiscoveryTime;
#endif
} tsCLD_ConcentratorParameters;
```

where:

- bConcentratorFlag is a Boolean flag which, when set to TRUE, enables the device as a concentrator for many-to-one routing. The default value is FALSE.

- u8ConcentratorRadius is the hop-count radius for concentrator route discoveries. The default value is 0x0F.
- u8ConcentratorDiscoveryTime is the time-interval, in seconds, between consecutive discoveries of inbound routes initiated by the concentrator. The default value is 0x0000, indicating that this time-interval is unknown and the discoveries must be triggered by the application.

Parent topic: Commissioning Cluster structure and attributes

Parent topic:*Commissioning Cluster*

Attribute Settings The Commissioning cluster structure contains only optional attributes. Each attribute is enabled/disabled through a corresponding macro defined in the **zcl_options.h** file (see Section 43.10) - for example, u16ShortAddress is enabled/disabled through the macro CLD_COMM_ATTR_SHORT_ADDRESS.

The function **eCLD_CommissioningSetAttribute()** can be used on the cluster server to write values to any one of the four attribute sets of the Commissioning cluster.

Parent topic:*Commissioning Cluster*

Initialisation The function **eCLD_CommissioningClusterCreateCommissioning()** is used to create an instance of the Commissioning cluster. The function is generally called by the initialization function for the host device.

Parent topic:*Commissioning Cluster*

Commissioning Commands A number of commissioning commands are provided to allow a Commissioning cluster client to remotely request actions relating to the Start-up Parameters attribute set (see Section 43.2.1) on a cluster server. This includes initiating a device restart from the current Start-up Parameter values, as well as the management of these attributes.

Device Start-up The 'current' set of Start-up Parameter values on a cluster server are those used in the start-up procedure, which can be remotely initiated from a cluster client using the function **eCLD_CommissioningCommandRestartDeviceSend()**. This function sends a Restart Device command to the remote device hosting the cluster server. This command provides a number of options concerning the timing of the restart:

- **Without delay:** The start-up procedure is invoked as soon as the command is received. This option requires both the delay and jitter to be specified as zero.
- **With delay:**The start-up procedure is invoked after a specified delay (in seconds). If no delay is required, the delay period must be specified as zero.
- **With delay and jitter:** The start-up procedure is invoked after a specified delay (in seconds) with a random jitter period added. It is necessary to indicate a maximum jitter period but the actual period will be randomly generated. If no jitter is required, the maximum jitter period must be specified as zero.

Note: If only jitter is required, the delay period must be specified as zero and the maximum jitter period must be non-zero.

In all of the above cases, it is possible to configure the start-up procedure to begin either without any further delay or at a 'convenient' moment (when there are no pending actions that should be completed before the restart).

The above options are configured in the command payload (see Section 43.9.2).

The cluster server will send a Restart Device Response to the requesting client before invoking the start-up procedure or starting the countdown (for the delay).

Parent topic: Commissioning Commands

Stored Start-up Parameters In addition to the 'current' set of values for the Start-up Parameters attribute set, the cluster server can store other sets of values for these attributes in non-volatile memory. Each stored set of Start-up Parameter values is assigned a unique index number. At any time, a particular stored set of values can be retrieved and loaded to become the current set. Functions are provided for managing the saved sets of Start-up Parameter values.

Saving Start-up Parameters In order to save a set of Start-up Parameter values, it is first necessary to set them as the current attribute values - this must be done locally by the application on the device hosting the server, possibly using the function **eCLD_CommissioningSetAttribute()**.

The application on a device hosting a cluster client can send a Save Start-up Parameters command to the cluster server in order to request that the current set of Start-up Parameter values is saved to non-volatile memory. This can be done by calling **eCLD_CommissioningCommandSaveStartupParamsSend ()** or, alternatively, **eCLD_CommissioningCommandModifyStartupParamsSend ()**. The index number of the saved record must be specified in the request. If this number has already been used, the existing stored values will be over-written with the new values.

It is the responsibility of the user application on the device hosting the server to perform the save. When the command arrives, a ZCL custom event will be generated and the request should be handled by the user-defined callback function for the endpoint on which the application is located. The server will automatically send a Save Start-up Parameters Response to the requesting client.

Parent topic: Stored Start-up Parameters

Retrieving Stored Start-up Parameters A set of Start-up Parameter values that have been stored by in non-volatile memory (as described in Section 43.5.2.1) can be retrieved and loaded as the current set of values. The required stored set of values is specified using its unique index number.

The application on a device hosting a cluster client can send a Restore Start-up Parameters command to the cluster server in order to request that the specified set of Start-up Parameter values is loaded from non-volatile memory. This can be done by calling **eCLD_CommissioningCommandRestoreStartupParamsSend ()** or, alternatively, **eCLD_CommissioningCommandModifyStartupParamsSend ()**. The index number of the relevant set must be specified in the request.

It is the responsibility of the user application on the device hosting the server to retrieve the relevant set of values and load them as the current values. When the command arrives, a ZCL custom event will be generated and the request should be handled by the user-defined callback function for the endpoint on which the application is located. The server will automatically send a Restore Start-up Parameters Response to the requesting client.

A device restart is required in order to implement the loaded values, as described in Section 43.5.1.

Parent topic: Stored Start-up Parameters

Parent topic: Commissioning Commands

Reset Start-up Parameters to Default Values A set of Start-up Parameters on the cluster server can be reset to their default values.

The application on a device hosting a cluster client can send a Reset Start-up Parameters command to the cluster server in order to request that the Start-up Parameters are reset to their default values. This can be done by calling **eCLD_CommissioningCommandResetStartupParamsSend ()** or, alternatively,

eCLD_CommissioningCommandModifyStartupParamsSend (). Options are available concerning the set(s) of Start-up Parameters to reset - any combination of the following can be performed:

- Reset the current set of Start-up Parameters
- Reset all stored sets of Start-up Parameters or the stored set with given index
- Erase the stored set of Start-up Parameters with given index

The required options must be specified in the request. The option to erase a stored set of Start-up Parameters allows storage space to be freed up.

It is the responsibility of the user application on the device hosting the server to reset the relevant set(s) of values. When the command arrives, a ZCL custom event will be generated and the request should be handled by the user-defined callback function for the endpoint on which the application is located. The server will automatically send a Reset Start-up Parameters Response to the requesting client.

A device restart is required in order to implement the reset (current) values, as described in Section 43.5.1.

Parent topic: Commissioning Commands

Parent topic:*Commissioning Cluster*

Commissioning Events The Commissioning cluster has its own events that are handled through the callback mechanism outlined in *Chapter 3*. If a device uses this cluster then application-specific Commissioning event handling must be included in the user-defined callback function for the associated endpoint, where this callback function is registered through the relevant endpoint registration function. This callback function will then be invoked when a Commissioning event occurs and needs the attention of the application.

For a Commissioning event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsCLD_CommissioningCallBackMessage structure (fully detailed in Section43.9.6).

```
typedef struct
{
    uint8                   u8CommandId;
    union
    {
        tsCLD_Commissioning_RestartDevicePayload
                            *psRestartDevicePayload;
        tsCLD_Commissioning_ModifyStartupParametersPayload
                            *psModifyStartupParamsPayload;
    } uReqMessage;
    union
    {
        tsCLD_Commissioning_ResponsePayload
                            *psCommissioningResponsePayload;
    } uRespMessage;
} tsCLD_CommissioningCallBackMessage;
```

When a Commissioning event occurs, one of a number of command types could have been received. The relevant command type is specified through the u8CommandId field of the tsCLD_CommissioningCallBackMessage structure. The possible command types are detailed below.

The table below details the command types that can be received by the cluster server.

u8CommandId Enumeration	Description
E_CLD_COMMISSIONING_CMD_RESTART_DEVI	A Restart Device command has been received
E_CLD_COMMISSIONING_CMD_SAVE_STARTUP	A Save Start-up Parameters command has been received
E_CLD_COMMISSIONING_CMD_RESTORE_STAR	A Restore Start-up Parameters command has been received
E_CLD_COMMISSIONING_CMD_RESET_STARTU	A Reset Start-up Parameters command has been received

The table below details the command types that can be received by the cluster client.

u8CommandId Enumeration	Description
E_CLD_COMMISSIONING_CMD_RESTART_DEVI(	A Restart Device response has been received
E_CLD_COMMISSIONING_CMD_SAVE_STARTUP_	A Save Start-up Parameters response has been received
E_CLD_COMMISSIONING_CMD_RESTORE_STAR'	A Restore Start-up Parameters response has been received
E_CLD_COMMISSIONING_CMD_RESET_STARTU_	A Reset Start-up Parameters response has been received

Parent topic:*Commissioning Cluster*

Functions The following Commissioning cluster function is provided:

1. eCLD_CommissioningClusterCreateCommissioning
2. eCLD_CommissioningCommandRestartDeviceSend
3. eCLD_CommissioningCommandSaveStartupParamsSend
4. eCLD_CommissioningCommandRestoreStartupParamsSend
5. eCLD_CommissioningCommandResetStartupParamsSend
6. eCLD_CommissioningCommandModifyStartupParamsSend
7. eCLD_CommissioningSetAttribute

eCLD_CommissioningClusterCreateCommissioning

```
teZCL_Status eCLD_CommissioningClusterCreateCommissioning(
    tsZCL_ClusterInstance *psClusterInstance,
    bool_t bIsServer,
    tsZCL_ClusterDefinition *psClusterDefinition,
    void *pvEndPointSharedStructPtr,
    uint8 *pu8AttributeControlBits,
    tsCLD_CommissioningCustomDataStructure
    *psCustomDataStructure);
```

Description This function creates an instance of the Commissioning cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function will create a Commissioning cluster instance on the endpoint, but instances of

other clusters may also be created on the same endpoint by calling their corresponding creation functions. For more details of creating cluster instances on custom endpoints, refer to *Appendix D.*

Note: This function must not be called for an endpoint on which a standard ZigBee device is used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function from those described in the *ZigBee Devices User Guide*

Note: *(JNUG3131)*.

When used, this function must be called after the stack has been started and after the ZCL has been initialized.

The function requires an array to be declared for internal use, which contains one element (of type **uint8**) for each attribute of the cluster. The array length is automatically adjusted by the compiler using the following declaration:

```
uint8 au8CommissioningAttributeControlBits
[(sizeof(asCLD_CommissioningClusterAttributeDefinitions) / sizeof(tsZCL_AttributeDefinition))];
```

Parameters

- *psClusterInstance* Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initialising individual structure fields.
- *bIsServer* Type of cluster instance (server or client) to be created:
- TRUE - server
- FALSE - client
- *psClusterDefinition* Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the Commissioning cluster. This parameter can refer to a pre-filled structure called sCLD_Commissioning which is provided in the **Commissioning.h** file.
- *pvEndPointSharedStructPtr* Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_Commissioning which defines the attributes of Commissioning cluster. The function initializes the attributes with default values.
- *pu8AttributeControlBits* Pointer to an array of **uint8** values, with one element for each attribute in the cluster (see above). For a cluster client, set this pointer to NULL.
- *psCustomDataStructure* Pointer to a structure containing the storage for internal functions of the cluster (see Section 43.9.5)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_CommissioningCommandRestartDeviceSend

```
teZCL_Status eCLD_CommissioningCommandRestartDeviceSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber, tsCLD_Commissioning_RestartDevicePayload *psPayload);
```

Description This function can be used on a Commissioning cluster client to send a Restart Device command to a cluster server on a remote device. This command is used to run the start-up procedure with a new set of values for the Start-up Parameters attributes (these values must already be installed). The new values may be implemented immediately or after a specified delay with an optional jitter.

When the command arrives, a ZCL custom event will be generated and the request should be handled by the user-defined callback function for the endpoint on which the application is located (see Section 43.6). Before running the start-up procedure or starting the countdown (for the delay), the server will send a Restart Device Response to the requesting client, where a ZCL custom event will be generated.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId* Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress* Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber* Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload* Pointer to a structure containing the payload for this message (see Section 43.9.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_CommissioningCommandSaveStartupParamsSend

```
teZCL_Status eCLD_CommissioningCommandSaveStartupParamsSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
```

(continues on next page)

(continued from previous page)

```
uint8 *pu8TransactionSequenceNumber
tsCLD_Commissioning_ModifyStartupParametersPayload *psPayload);
```

Description This function can be used on a Commissioning cluster client to send a Save Start-up Parameters command to a cluster server on a remote device. This command instructs the server to locally save a set of values for the attributes of the Start-up Parameters attribute set. A device can store different sets of start-up parameters (in non-volatile memory), with each set being referenced using an index number. This index number must be specified and if a set has already been stored with the same index number then the stored values will be over-written with the new values.

It is the responsibility of the user application on the device hosting the server to implement the command. When the command arrives, a ZCL custom event will be generated and the request should be handled by the user-defined callback function for the endpoint on which the application is located (see Section 43.6). The server will automatically send a Save Start-up Parameters Response to the client, where a ZCL custom event will be generated.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId* Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress* Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber* Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload* Pointer to a structure containing the payload for this message (see Section 43.9.3)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_CommissioningCommandRestoreStartupParamsSend

```
teZCL_Status eCLD_CommissioningCommandRestoreStartupParamsSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber, tsCLD_Commissioning_*psPayload)
```

Description This function can be used on a Commissioning cluster client to send a Restore Start-up Parameters command to a cluster server on a remote device. This command instructs the server to load a saved set of values for the attributes of the Start-up Parameters attribute set. The index of the required set of Start-up Parameters must be specified in the command payload. Note that the command does not instruct the server to implement the loaded values using the start-up procedure - a Restart Device command is required to do this.

It is the responsibility of the user application on the device hosting the server to implement the command. When the command arrives, a ZCL custom event will be generated and the request should be handled by the user-defined callback function for the endpoint on which the application is located (see Section 43.6). The server will automatically send a Restore Start-up Parameters Response to the client, where a ZCL custom event will be generated.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId* Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress* Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber* Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload* Pointer to a structure containing the payload for this message (see Section 43.9.3)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_CommissioningCommandResetStartupParamsSend

```
teZCL_Status eCLD_CommissioningCommandResetStartupParamsSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber, tsCLD_*psPayload);
```

Description This function can be used on a Commissioning cluster client to send a Reset Start-up Parameters command to a cluster server on a remote device. This command instructs the server to set the current Start-up Parameters to their default values. It is also possible to set one or all of any saved sets of Start-up Parameters to the defaults. The command can also be used to delete a specified set of saved Start-up Parameters.

It is the responsibility of the user application on the device hosting the server to implement the command. When the command arrives, a ZCL custom event will be generated and the request should be handled by the user-defined callback function for the endpoint on which the application is located (see Section 43.6). The server will automatically send a Reset Start-up Parameters Response to the client, where a ZCL custom event will be generated.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId* Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress* Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber* Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload* Pointer to a structure containing the payload for this message (see Section 43.9.3)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_CommissioningCommandModifyStartupParamsSend

```
teZCL_Status eCLD_CommissioningCommandModifyStartupParamsSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_Commissioning_ModifyStartupParametersPayload *psPayload,
    teCLD_Commissioning_Command eCLD_Commissioning_Command);
```

Description This function can be used on a Commissioning cluster client to send a command to modify a set of values for the Start-up Parameters attributes in the cluster server on a remote device. One of four commands can be specified and sent, as listed and described in the table below:

Command	Description
Restart Device	Used to run the start-up procedure with the current set of values for the Start-up Parameters attributes, as described for the function **eCLD_CommissioningCommandRestartDeviceSend()**. These values may have been loaded using the Restore Start-up Parameters or Reset Start-up Parameters command.
Save Start-up Parameters	Used to save the current set of Start-up Parameter values with the specified index, as described for the function **eCLD_CommissioningCommandSaveStartupParamsSend()**.
Restore Start-up Parameters	Used to load the saved set of Start-up Parameter values with the specified index, such that these values become the current Start-up Parameter val-ues, as described for the function **eCLD_CommissioningCommandRe-storeStartupParamsSend()**. Note that these values are not implemented, which requires a Restart Device command.
Reset Start-up Parameters	Used to reset the current Start-up Parameters to their defaults. One or all of any stored sets of Start-up Parameter values can also be reset to the defaults, as described for the function **eCLD_CommissioningComman-dResetStartupParamsSend()**. The command can also be used to delete a particular set of stored Start-up Parameters.

It is the responsibility of the user application on the device hosting the server to implement the command. When the command arrives, a ZCL custom event will be generated and the request should be handled by the user-defined callback function for the endpoint on which the application is located (see Section 43.6). The server will automatically send a response for the relevant command to the client, where a ZCL custom event will be generated.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which to send the request. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values

- *u8DestinationEndPointId* Number of the endpoint on the remote node to which the request is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress* Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber* Pointer to a location to receive the Transaction Sequence Number (TSN) of the request
- *psPayload* Pointer to a structure containing the payload for this message (see Section 43.9.3)
- *eCLD_Commissioning_Command* Type of command to send, one of:
- E_CLD_COMMISSIONING_CMD_RESTART_DEVICE
- E_CLD_COMMISSIONING_CMD_SAVE_STARTUP_PARAMS
- E_CLD_COMMISSIONING_CMD_RESTORE_STARTUP_PARAMS
- E_CLD_COMMISSIONING_CMD_RESET_STARTUP_PARAMS

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_CommissioningSetAttribute

```
teZCL_Status eCLD_CommissioningSetAttribute(
    uint8 u8SourceEndPointId,
    teCLD_Commissioning_AttributeSet eAttributeSet,
    void *vptrAttributeSetStructure);
```

Description { This function can be used on a Commissioning cluster server to write values to a particular attribute set of the Commissioning cluster.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which to issue the request.
- *eAttributeSet* Enumeration indicating attribute set to write to, one of:
- E_CLD_COMMISSIONING_ATTR_SET_STARTUP_PARAMS
- E_CLD_COMMISSIONING_ATTR_SET_JOIN_PARAMS
- E_CLD_COMMISSIONING_ATTR_SET_ENDDEVICE_PARAMS
- E_CLD_COMMISSIONING_ATTR_SET_CONCENTRATOR_PARAMS
- *vptrAttributeSetStructure* Pointer to a structure containing the new values for the attribute set - the relevant structures are detailed in Section 43.2

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic:*Commissioning Cluster*

Enumerations

teCLD_Commissioning_AttributeID The following structure contains the enumerations used to identify the attributes of the Commissioning cluster.

```
typedef enum
{
    E_CLD_COMMISSIONING_ATTR_ID_SHORT_ADDRESS            = 0x0000,
    E_CLD_COMMISSIONING_ATTR_ID_EXT_PANID,
    E_CLD_COMMISSIONING_ATTR_ID_PANID,
    E_CLD_COMMISSIONING_ATTR_ID_CHANNEL_MASK,
    E_CLD_COMMISSIONING_ATTR_ID_PROTOCOL_VERSION,
    E_CLD_COMMISSIONING_ATTR_ID_STACK_PROFILE,
    E_CLD_COMMISSIONING_ATTR_ID_STARTUP_CONTROl,
    E_CLD_COMMISSIONING_ATTR_ID_TC_ADDR                  = 0x0010,
    E_CLD_COMMISSIONING_ATTR_ID_TC_MASTER_KEY,
    E_CLD_COMMISSIONING_ATTR_ID_NETWORK_KEY,
    E_CLD_COMMISSIONING_ATTR_ID_USE_INSECURE_JOIN,
    E_CLD_COMMISSIONING_ATTR_ID_PRECONFIG_LINK_KEY,
    E_CLD_COMMISSIONING_ATTR_ID_NWK_KEY_SEQ_NO,
    E_CLD_COMMISSIONING_ATTR_ID_NWK_KEY_TYPE,
    E_CLD_COMMISSIONING_ATTR_ID_NWK_MANAGER_ADDR,
    E_CLD_COMMISSIONING_ATTR_ID_SCAN_ATTEMPTS            = 0x0020,
    E_CLD_COMMISSIONING_ATTR_ID_TIME_BW_SCANS,
    E_CLD_COMMISSIONING_ATTR_ID_REJOIN_INTERVAL,
    E_CLD_COMMISSIONING_ATTR_ID_MAX_REJOIN_INTERVAL,
    E_CLD_COMMISSIONING_ATTR_ID_INDIRECT_POLL_RATE       = 0x0030,
    E_CLD_COMMISSIONING_ATTR_ID_PARENT_RETRY_THRSHOLD,
    E_CLD_COMMISSIONING_ATTR_ID_CONCENTRATOR_FLAG        = 0x0040,
    E_CLD_COMMISSIONING_ATTR_ID_CONCENTRATOR_RADIUS,
    E_CLD_COMMISSIONING_ATTR_ID_CONCENTRATOR_DISCVRY_TIME,
} teCLD_Commissioning_AttributeID;;
```

Parent topic: Enumerations

teCLD_Commissioning_AttributeSet The following structure contains the enumerations used to identify the attribute sets of the Commissioning cluster.

```
typedef enum
{
    E_CLD_COMMISSIONING_ATTR_SET_STARTUP_PARAMS       = 0x00,
    E_CLD_COMMISSIONING_ATTR_SET_JOIN_PARAMS,
    E_CLD_COMMISSIONING_ATTR_SET_ENDDEVICE_PARAMS,
    E_CLD_COMMISSIONING_ATTR_SET_CONCENTRATOR_PARAMS
} teCLD_Commissioning_AttributeSet;
```

Parent topic: Enumerations

teCLD_Commissioning_Command The following structure contains the enumerations used to identify commands of the Commissioning cluster (the same enumerations are used for requests and their corresponding responses).

```
typedef enum
{
    E_CLD_COMMISSIONING_CMD_RESTART_DEVICE              = 0x00,
    E_CLD_COMMISSIONING_CMD_SAVE_STARTUP_PARAMS,
    E_CLD_COMMISSIONING_CMD_RESTORE_STARTUP_PARAMS,
    E_CLD_COMMISSIONING_CMD_RESET_STARTUP_PARAMS
} teCLD_Commissioning_Command;
```

The above enumerations are described in the table below:

Enumeration	Command
E_CLD_COMMISSIONING_CMD_RESTART_DEVICE	Restart Device request or response
E_CLD_COMMISSIONING_CMD_SAVE_STARTUP_PAI	Save Start-up Parameters request or response
E_CLD_COMMISSIONING_CMD_RESTORE_STARTUP_	Restore Start-up Parameters request or response
E_CLD_COMMISSIONING_CMD_RESET_STARTUP_PA	Reset Start-up Parameters request or response

Parent topic: Enumerations

Parent topic:*Commissioning Cluster*

Structures

Attribute Set Structures The following structures contain the Commissioning cluster attribute sets and are detailed in the referenced sections:

- tsCLD_StartupParameters - see Section 43.2.1
- tsCLD_JoinParameters - see Section 43.2.2
- tsCLD_EndDeviceParameters - see Section 43.2.3
- tsCLD_ConcentratorParameters - see Section 43.2.4

Parent topic: Structures

tsCLD_Commissioning_RestartDevicePayload The following structure contains the payload of a Restart Device command.

```
typedef struct
{
    zbmap8                  u8Options;
    uint8                   u8Delay;
    uint8                   u8Jitter;
} tsCLD_Commissioning_RestartDevicePayload;
```

where:

u8Options is a 8-bit bitmap specifying the required start-up options:

Bits	Option	Description
0-2	Start-up Mode	Determines the starting state of the device restart:

- 0b000: Restart with current Start-up Parameter values
- 0b001: Restart from existing stack state

All other values are reserved.

| |3|Immediate|Determines how quickly the start-up procedure will begin follow-ing receipt of the command or the specified delay/jitter:

- 1: Immediately
- 0: At a convenient moment (e.g. following any pending actions)

| |4-7|-|Reserved|

u8Delay specifies the time-delay, in seconds, before the start-up procedure should be executed.
u8Jitter is a value which determines the possible range of values of the jitter that is added to the delay u8Delay - ↪ the jitter, in milliseconds, is a random value in the range 0 to u8Jitter x 80.

Parent topic: Structures

tsCLD_Commissioning_ModifyStartupParametersPayload The following structure contains the payload of the following commands: Save Start-up Parameters, Restore Start-up Parameters and Reset Start-up Parameters.

```
typedef struct
{
    zbmap8                  u8Options;
    uint8                   u8Index;
} tsCLD_Commissioning_ModifyStartupParametersPayload;
```

where:

u8Options is an 8-bit bitmap specifying the required reset options for the Reset Start- ↪up Parameters command (it is not used by the other commands):

Bits	Option	Description
0	Reset Current	Determines whether the current Start-up Parameters will be reset to their default values:

- 1: Reset to default values
- 0: Do not reset (remain unchanged)

| |1|Reset All|Determines whether all stored Start-up Parameter sets will be reset to their default values:

- 1: Reset all stored Start-up Parameter sets
- 0: Reset the stored Start-up Parameter set with specified index

| |2|Erase Index|Determines whether the stored Start-up Parameter set with speci-fied index will be erased:

- 1: Erase Start-up Parameter set with specified index
- 0: Do not erase Start-up Parameter set with specified index

| |3-7|-|Reserved|

```
u8Index is the index of the saved Start-
↪up Parameter set to which actions specified in u8Options relate (this index is ignored if no actions are specified).
```

Parent topic: Structures

tsCLD_Commissioning_ResponsePayload The following structure contains the payload of the responses to the following commands: Save Start-up Parameters, Restore Start-up Parameters and Reset Start-up Parameters.

```
typedef struct
{
    zenum8                  u8Status;
} tsCLD_Commissioning_ResponsePayload;
```

where u8Status contains one of the ZCL command status codes listed and described in Section 7.1.4.

Parent topic: Structures

tsCLD_CommissioningCustomDataStructure The Commissioning cluster requires extra storage space to be allocated to be used by internal functions. The structure definition for this storage is shown below:

```
typedef struct
{
    tsZCL_ReceiveEventAddress               sReceiveEventAddress;
    tsZCL_CallBackEvent                     sCustomCallBackEvent;
    tsCLD_CommissioningCallBackMessage      sCallBackMessage;
} tsCLD_CommissioningCustomDataStructure;
```

The fields are for internal use and no knowledge of them is required.

Parent topic: Structures

tsCLD_CommissioningCallBackMessage For a Commissioning event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsCLD_CommissioningCallBackMessage structure:

```
typedef struct
{
    uint8                       u8CommandId;
    union
    {
        tsCLD_Commissioning_RestartDevicePayload
                            *psRestartDevicePayload;
        tsCLD_Commissioning_ModifyStartupParametersPayload
                            *psModifyStartupParamsPayload;
    } uReqMessage;
    union
```

(continues on next page)

(continued from previous page)

```
    {
        tsCLD_Commissioning_ResponsePayload
                        *psCommissioningResponsePayload;
    } uRespMessage;
} tsCLD_CommissioningCallBackMessage;
```

where:

- u8CommandId indicates the type of Commissioning command that has been received by a cluster server or client (the same enumerations are used for requests on the server and responses on the client), one of:
  - E_CLD_COMMISSIONING_CMD_RESTART_DEVICE
  - E_CLD_COMMISSIONING_CMD_SAVE_STARTUP_PARAMS
  - E_CLD_COMMISSIONING_CMD_RESTORE_STARTUP_PARAMS
  - E_CLD_COMMISSIONING_CMD_RESET_STARTUP_PARAMS
- uReqMessage is a union containing the payload of a request command in the following form:
  - psRestartDevicePayload is a pointer to a structure containing the Restart Device command payload - see Section 43.9.2
  - psModifyStartupParamsPayload is a pointer to a structure containing the (common) payload for the Save Start-up Parameters, Restore Start-up Parameters and Reset Start-up Parameters commands - see Section43.9.3
- uRespMessage is a union containing the payload of a response command in the following form:
  - psCommissioningResponsePayload is a pointer to a structure containing the (common) payload for the Save Start-up Parameters, Restore Start-up Parameters and Reset Start-up Parameters responses - see Section 43.9.4

For further information on Commissioning cluster events, refer to Section 43.6.

Parent topic: Structures

Parent topic:*Commissioning Cluster*

Compile-time options To enable the Commissioning cluster in the code to be built, it is necessary to add the following to the **zcl_options.h** file:

```
#define CLD_COMMISSIONING
```

In addition, to include the software for a cluster client or server or both, it is necessary to add one or both of the following to the same file:

```
#define COMMISSIONING_CLIENT
#define COMMISSIONING_SERVER
```

Optional Attributes The Commissioning cluster contains attributes that may be optionally enabled at compile-time by adding some or all of the following lines to the **zcl_options.h** file (see Section 43.2 and Section 43.3):

```
#define        CLD_COMM_ATTR_SHORT_ADDRESS
#define CLD_COMM_ATTR_EXTENED_PAN_ID
#define CLD_COMM_ATTR_PAN_ID
#define CLD_COMM_ATTR_CHANNEL_MASK
#define CLD_COMM_ATTR_PROTOCOL_VERSION
#define CLD_COMM_ATTR_STACK_PROFILE
#define CLD_COMM_ATTR_START_UP_CONTROL
      #define CLD_COMM_ATTR_TC_ADDR
#define CLD_COMM_ATTR_TC_MASTER_KEY
      #define CLD_COMM_ATTR_NWK_KEY
#define CLD_COMM_ATTR_USE_INSECURE_JOIN
      #define CLD_COMM_ATTR_PRE_CONFIG_LINK_KEY
#define CLD_COMM_ATTR_NWK_KEY_SEQ_NO
      #define CLD_COMM_ATTR_NWK_KEY_TYPE
#define CLD_COMM_ATTR_NWK_MANAGER_ADDR
#define CLD_COMM_ATTR_SCAN_ATTEMPTS
#define CLD_COMM_ATTR_TIME_BW_SCANS
#define CLD_COMM_ATTR_REJOIN_INTERVAL
#define CLD_COMM_ATTR_MAX_REJOIN_INTERVAL
      #define CLD_COMM_ATTR_INDIRECT_POLL_RATE
#define CLD_COMM_ATTR_PARENT_RETRY_THRSHLD
#define CLD_COMM_ATTR_CONCENTRATOR_FLAG
#define CLD_COMM_ATTR_CONCENTRATOR_RADIUS
#define CLD_COMM_ATTR_CONCENTRATOR_DISCVRY_TIME
```

Optional Commands The Commissioning cluster contains commands that may be optionally enabled at compile-time by adding some or all of the following lines to the **zcl_options.h** file.

To enable the Save Start-up Parameters command, add the following line:

```
#define CLD_COMMISSIONING_CMD_SAVE_STARTUP_PARAMS
```

To enable the Restore Start-up Parameters command, add the following line:

```
#define CLD_COMMISSIONING_CMD_RESTORE_STARTUP_PARAMS
```

Parent topic:*Commissioning Cluster*

Touchlink Commissioning Cluster This chapter describes the Touchlink Commissioning cluster, which can be used when forming a network or adding a new node to an existing network.

The Touchlink Commissioning cluster has a Cluster ID of 0x1000.

Overview The Touchlink Commissioning cluster is associated with a node as a whole, rather than with individual ZigBee devices on the node. It must be used on nodes that incorporate one or more of the ZigBee devices indicated in *Table 83* below, which shows the supported devices when the Touchlink Commissioning cluster acts as a client, server and combined client/server.

Client	Client/Server	Server
Colour Controller	Colour Controller	Colour Controller
Colour Scene Controller	Colour Scene Controller	Colour Scene Controller
Non-Colour Controller	Non-Colour Controller	Non-Colour Controller
Non-Colour Scene Controller	Non-Colour Scene Controller	Non-Colour Scene Controller
Control Bridge	Control Bridge	Control Bridge
On/Off Sensor	On/Off Sensor	On/Off Sensor
	On/Off Light	On/Off Light
	On/Off Plug-in Unit	On/Off Plug-in Unit
	Dimmable Light	Dimmable Light
	Dimmable Plug-in Unit	Dimmable Plug-in Unit
	Colour Light	Colour Light
	Extended Colour Light	Extended Colour Light
	Colour Temperature Light	Colour Temperature Light

This cluster supports two sets of functionality, corresponding to two distinct commands sets:

- Touchlink
- Commissioning Utility

Functions are provided for implementing both sets of commands. These functions are referenced in Section 44.4 and Section 44.5, and detailed in Section 44.7.

The Commissioning Utility functionality is not required on Lighting devices.

For the compile-time options for enabling the Touchlink Commissioning cluster for Touchlink and the Commissioning Utility, refer to Section 44.10.

Parent topic:*Touchlink Commissioning Cluster*

Cluster structure and attributes This cluster has no attributes, as a server or a client. Therefore, the cluster structure tsCLD_ZllCommission is referred to using a null pointer.

Parent topic:*Touchlink Commissioning Cluster*

Commissioning operations Commissioning involves forming a network or adding a new node to an existing network. A node from which commissioning can be initiated is referred to as an 'initiator' - this may be a remote control unit, but could also be a lamp.

- An 'initiator' node must support the Touchlink Commissioning cluster as a client.
- A node to be added to the network must support the Touchlink Commissioning cluster as a server (or as both a server and client).

Note that commissioning a new network involves adding at least one node to the new network (as well as the initiator).

Commissioning may involve two stages, depending on the type of node added to the network by the initiator:

1. The node is added to the network using the Touchlink commands of the Touchlink Commissioning cluster. In practice for the user, this typically involves bringing the initiator node physically close to the target node and pressing a button.

2. If the initiator node and the new node will both be used to control lights in the network, the new node must learn certain information (such as controlled endpoints and configured groups) from the initiator. This exchange of information uses the Commissioning Utility commands of the Touchlink Commissioning cluster.

Note: **Note:**The Touchlink Commissioning cluster instance for Touchlink must reside on its own endpoint on a node. Therefore, a Touchlink commissioning application must be provided which is distinct from the main application. However, the cluster instance for the Commissioning Utility can reside on the same endpoint as the main application (and be used in this application).

Commissioning using the supplied functions for Touchlink and the Commissioning Utilty is described in Section 44.4 and Section 44.5.

Parent topic:*Touchlink Commissioning Cluster*

Using Touchlink Touchlink is used for the basic commissioning of a new network or adding a new node to an existing network. A dedicated Touchlink application (which is distinct from the main application on the node) must reside on its own endpoint. This requires:

- a Touchlink Commissioning cluster instance as a client to be created on the endpoint on the initiator node.
- a Touchlink Commissioning cluster instance as a server to be created on the endpoint on the target node.

The initiator node also requires a Touchlink Commissioning cluster instance as a server (on the same endpoint), since the node also needs the capability to join an existing network.

An endpoint is registered for Touchlink (on both nodes) using the function **eZLL_RegisterCommissionEndPoint()**. This function also creates a Touchlink Commissioning cluster instance of the type (server, client or both) determined by the compile-time options in the header file **zcl_options.h** (see Section 44.10).

The initiator must then send a sequence of request commands to the target node. The Touchlink request command set is summarized in Table 1. Touchlink functions for issuing these commands are provided and are detailed in Section 44.7.1.

Using Touchlink

Command	Identifier	Description
Scan Request *	0x00	Requests other devices (potential nodes) in the local neighbourhood to respond. A scan request is first performed on channel 11, up to five times until a response is received. If no response is received, a scan request is then performed once on each of channels 15, 20 and 25, and then the remaining channels (12, 13, 14, 16, etc) until a response is detected.
Device Information Request *	0x02	Requests information about the devices on a remote node
Identify Request	0x06	Requests a remote node to physically identify itself (for example, visually by flashing an LED)
Reset To Factory New Request	0x07	Requests a factory reset of a remote node
Network Start Request *	0x10	Requests a new network to be created comprising the initiator and a detected Router
Network Join Router Request *	0x12	Requests a Router to join the network
Network Join End Device Request *	0x14	Requests an End Device to join the network
Network Update Request *	0x16	Requests an update of the network settings on a remote node (if the supplied Network Update Identifier is more recent than the one on the node)

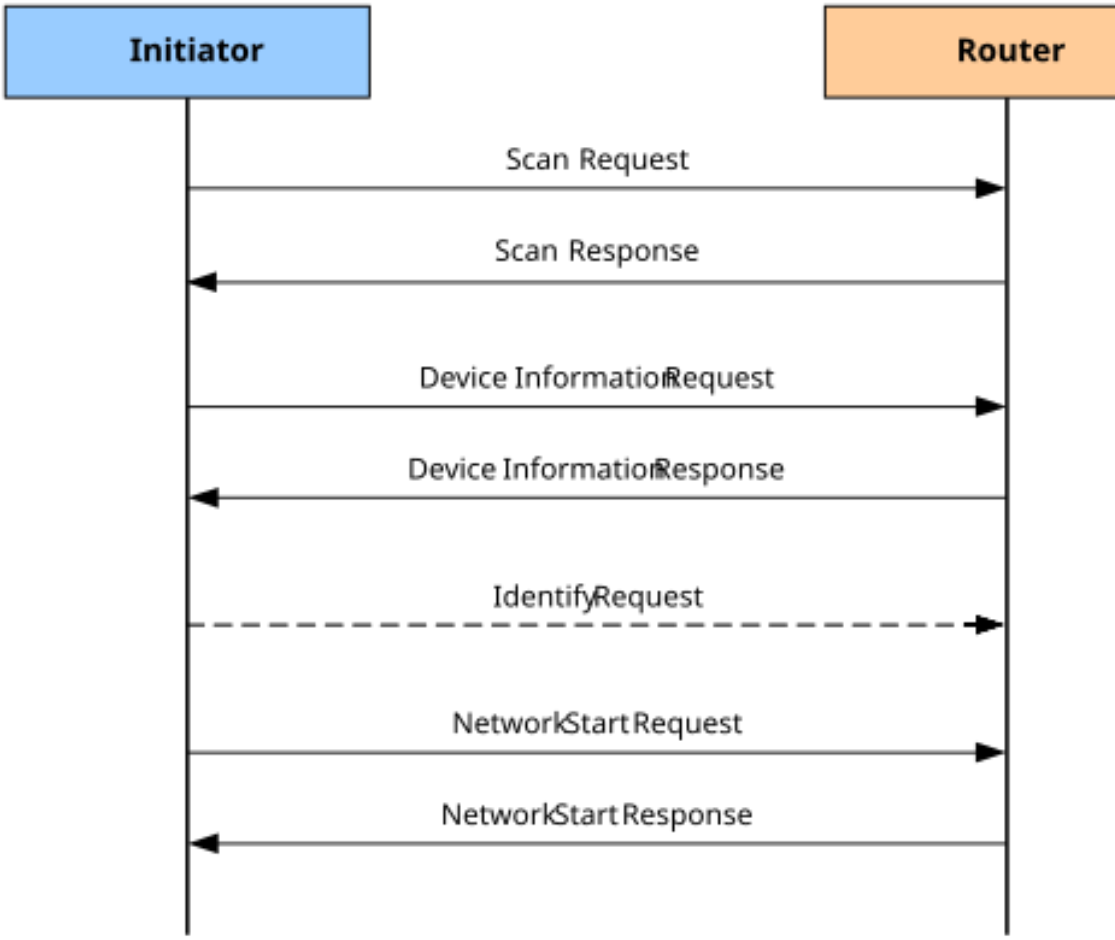
* These commands have corresponding responses.

All Touchlink commands are sent as inter-PAN messages.

Use of the above commands and associated functions is described in the sub-sections below.

Creating a network A network is formed from an initiator node and a Router node (usually the initiator is an End Device and will have no routing capability in the network). The Touchlink network creation process is described below and is illustrated in the figure below. (also refer to

the command list in the table in the Section Using Touchlink).



Note: Received Touchlink requests and responses are handled as ZigBee PRO events. The event handling is not detailed below but is outlined in Section 44.6.

1. **Scan Request:** The initiator sends a Scan Request to nodes in its vicinity. The required function is:
   eCLD_ZllCommissionCommandScanReqCommandSend\(\)
2. **Scan Response:** A receiving node replies to the Scan Request by sending a Scan Response, which includes the device type of the responding node (e.g. Router). The required function is: eCLD_ZllCommissionCommandScanRspCommandSend\(\)
3. **Device Information Request:** The initiator sends a Device Information Request to the detected Routers that are of interest. The required function is: eCLD_ZllCommissionCommandDeviceInfoReqCommandSend\(\)
4. **Device Information Response:** A receiving Router replies to the Device Information Request by sending a Device Information Response. The required function is:
   eCLD_ZllCommissionCommandDeviceInfoRspCommandSend\(\)
5. **Identify Request (Optional):** The initiator may send an Identify Request to the node which has been chosen as the first Router of the new network, in order to confirm that the correct physical node is being commissioned. The required function is:

   eCLD_ZllCommissionCommandDeviceIdentifyReqCommandSend\(\)
6. **Network Start Request:** The intiator sends a Network Start Request to the chosen Router in order to create and start the network. The required function is:
   eCLD_ZllCommissionCommandNetworkStartReqCommandSend\(\)
7. **Network Start Response:** The Router replies to the Network Start Request by sending a Network Start Response. The required function is: eCLD_ZllCommissionCommandNetworkStartRspCommandSend\(\)

Once the Router has started the network, the initiator joins the network (Router). The initiator then collects endpoint and cluster information from the Lighting device(s) on the Router node, and stores this information in a local lighting database.

Once the network (consisting of the initiator and one Router) is up and running, further nodes may be added as described in Section 44.4.2.

Creating a Network |

Parent topic: Using Touchlink

Adding to an existing network A network (that has been set up as described in Section 44.4.1) can be extended by adding a node. The Touchlink extension process is described below and illustrated in the figure below (also refer to the command list in Table 1).

Note: Received Touchlink requests and responses are handled as ZigBee PRO events. The event handling is not detailed below but is outlined in Section 44.6.

1. **Scan Request:** The initiator sends a Scan Request to nodes in its vicinity. The required function is:

- **eCLD_ZllCommissionCommandScanReqCommandSend()**

2. **Scan Response:** A receiving node replies to the Scan Request by sending a Scan Response. The required function is:

- **eCLD_ZllCommissionCommandScanRspCommandSend()**

3. **Device Information Request:** The initiator sends a Device Information Request to those detected nodes that are of interest. The required function is:

- **eCLD_ZllCommissionCommandDeviceInfoReqCommandSend()**

4. **Device Information Response:** A receiving node replies to the Device Information Request by sending a Device Information Response. The required function is:

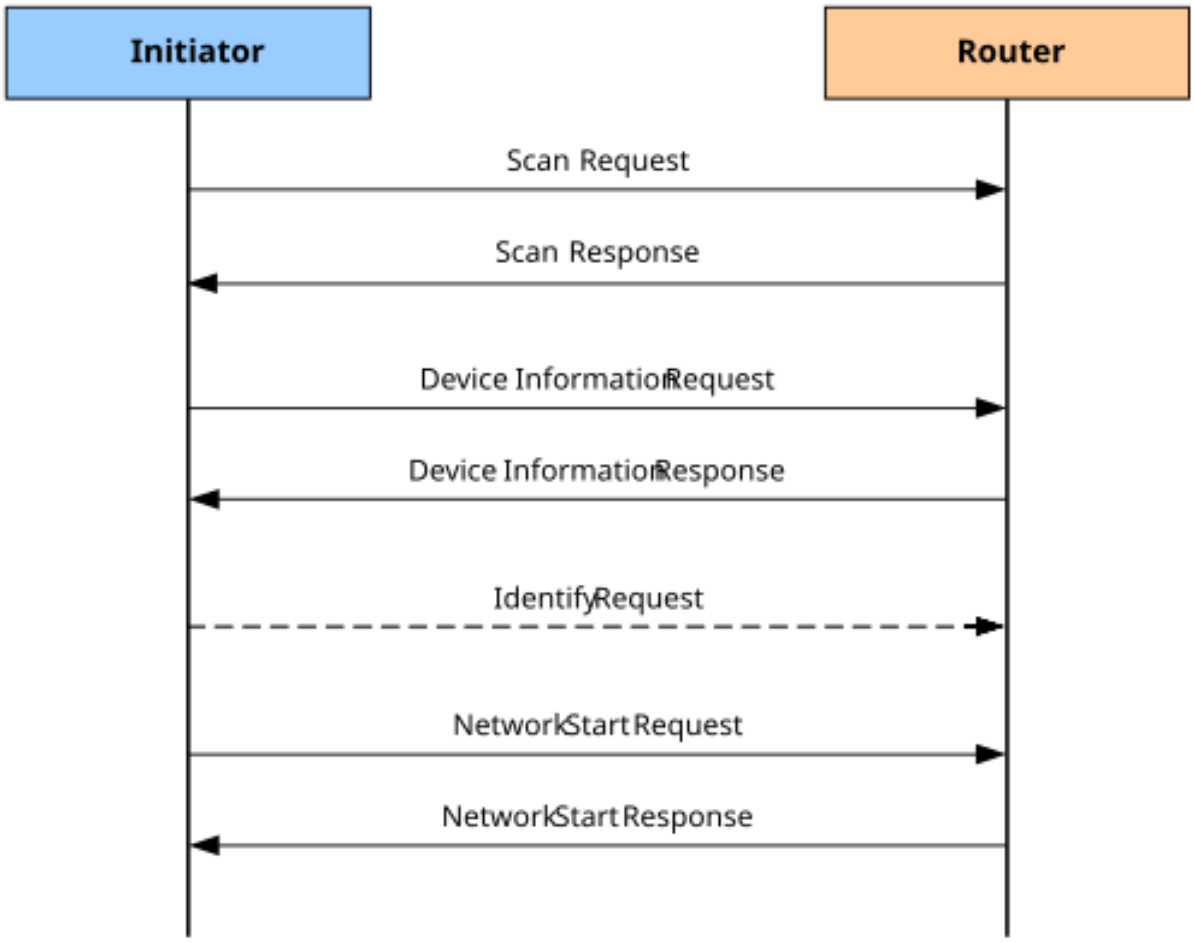
- **eCLD_ZllCommissionCommandDeviceInfoRspCommandSend()**

5. **Identify Request (Optional):** The initiator may send an Identify Request to the node which has been chosen to be added to the network, in order to confirm that the correct physical node is being commissioned. The required function is:

- **eCLD_ZllCommissionCommandDeviceIdentifyReqCommandSend()**

6. **Network Join Request:** Depending on the target node type, the initiator sends a Network Join Router Request or Network Join End Device Request, as appropriate, to the target node. The required function is one of:

- **eCLD_ZllCommissionCommandNetworkJoinRouterReqCommandSend()**
- **eCLD_ZllCommissionCommandNetworkJoinEndDeviceReqCommandSend()**



7. **Network Join Response:** Depending on the receiving node type, the node replies to the join request by sending a Network Join Router Response or Network Join End Device Response. The required function is one of:

- **eCLD_ZllCommissionCommandNetworkJoinRouterRspCommandSend()**
- **eCLD_ZllCommissionCommandNetworkJoinEndDeviceRspCommandSend()**

The node should now be a member of the network. The initiator then collects endpoint and cluster information from any Lighting device(s) on the new node, and stores this information in its local lighting database.

If the new node is to be used to control the light nodes of the network then it will need to learn certain information (such as controlled endpoints and configured groups) from the initiator - this is done using the Commissioning Utility commands, as described in Section 44.5.

Extending a Network (Adding a Node)

Parent topic: Using Touchlink

Updating network settings If one or more of the network settings change (e.g. the radio channel used), all nodes of the network need to be updated with the new settings.

To allow nodes to keep track of the status of the network settings, the Network Update Identifier is used. This identifier takes a value in the range 0x00 to 0xFF and is incremented when a network update has occurred (the value wraps around at 0xFF).

A node can be instructed to update its network settings by sending a Network Update Request to it. The required function is:

eCLD_ZllCommissionCommandNetworkUpdateReqCommandSend()

The payload of the sent command contains the latest network settings and the current value of the Network Update Identifier (see Section 44.8.17). If the payload value is more recent than the value held by the target node, the node should update its network settings with those in the payload.

Parent topic: Using Touchlink

Stealing a node A node that is already part of a network can be taken or 'stolen' by another network using Touchlink (in which case, the stolen node will cease to be a member of its previous network). This transfer can only be performed on a node which supports one or more Lighting devices (and not Controller devices).

The node is stolen using an initiator in the new network, e.g. from a remote control unit. The 'stealing' process is as follows:

1. The initiator sends a Scan Request to nodes in its vicinity. The required function is:

- **eCLD_ZllCommissionCommandScanReqCommandSend()**

2. A receiving node replies to the Scan Request by sending a Scan Response. The required function is:

- **eCLD_ZllCommissionCommandScanRspCommandSend()**

3. The initiator receives Scan Responses from one or more nodes and, based on these responses, selects a node (containing a Lighting device) that is already a member of another network.
4. The initiator then sends a Reset To Factory New Request to the desired node. The required function is:

- **eCLD_ZllCommissionCommandFactoryResetReqCommandSend()**

5. On receiving this request on the target node, the event E_CLD_COMMISSION_CMD_FACTORY_RESET_REQ is generated and the function **ZPS_eAplZdoLeaveNetwork()** should be called. In addition, all persistent data should be reset.
6. The node can then be commissioned into the new network by following the process in Section 44.4.2 from Step3.

Alternatively, instead of following the above process, a node can be stolen by either:

- Following the full process for creating a network in Section 44.4.1 and calling **ZPS_eAplZdoLeaveNetwork()**on the target node when a Network Start Request is received.
- Following the full process for adding a node in Section 44.4.2 and calling **ZPS_eAplZdoLeaveNetwork()**on the target node when a Network Join Router Request or Network Join End Device Request is received.

Note: If a node containing a Controller device (e.g. a remote control unit) is to be used in another network, it must first be reset using a Reset To Factory New Request. It can then be used to create a new network (see Section 44.4.1) or to learn the control information of an existing network (see Section 44.5).

Parent topic: Using Touchlink

Parent topic:*Touchlink Commissioning Cluster*

Using the Commissioning Utility The Commissioning Utility is used when a network node needs to learn lighting control information (such as controlled endpoints and configured groups) from another node in the network. It is typically used when a new remote control unit is introduced into the network and needs to learn information from an existing remote control unit.

Unlike Touchlink, the Commissioning Utility can be incorporated in the main application on the node (and therefore use the same endpoint). This requires:

- a Touchlink Commissioning cluster instance as a client to be created on the endpoint on the 'learner' node
- a Touchlink Commissioning cluster instance as a server to be created on the endpoint on the 'teacher' node

A Touchlink Commissioning cluster instance for the Commissioning Utility can be created using the function **eCLD_ZllUtilityCreateUtility()**, on both nodes.

It is the responsibility of the learner node to request the required information from the teacher node. The Commissioning Utility command set is summarised in *Table 85*. Commissioning Utility functions for issuing these commands are provided and are detailed in Section 44.7.2.

Command	Identifier	Description
Endpoint information	0x40	Sends information about local endpoint (from teacher to learner)
Get Group Identifiers Request	0x41	Requests Group information from a remote node (from learner to teacher)
Get Endpoint List Request	0x42	Requests endpoint information from a remote node (from learner to teacher)

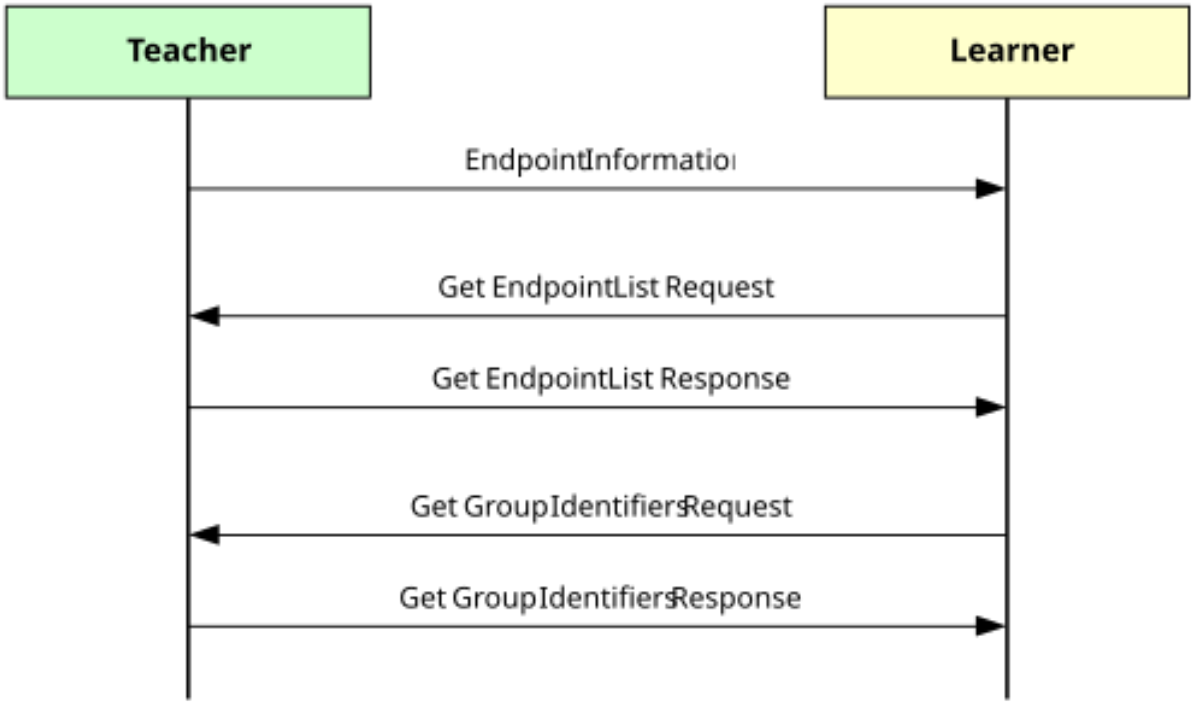
Use of the above commands and associated functions is described below and is illustrated in the figure below.

Note: Received Commissioning Utility requests and responses are handled as ZigBee PRO events by the ZCL (this event handling is therefore transparent to the application).

1. **Endpoint Information command:** The teacher node first sends an Endpoint Information command containing basic information about its local endpoint (IEEE address, network address endpoint number, Profile ID, Device ID) to the learner node. The required function is:

- **eCLD_ZllUtilityCommandEndpointInformationCommandSend()**
- Note that the teacher node will already have the relevant target endpoint on the learner node from the joining process (described in Section 44.4).

2. **Get Endpoint List Request:** The learner node then sends a Get Endpoint List Request to the teacher node to request information about the remote endpoints that the teacher node controls. The required function is:



- **eCLD_ZllUtilityCommandGetEndpointListReqCommandSend()**
- The teacher node automatically replies to the Get Endpoint List Request by sending a Get Endpoint List Response containing the requested information.

3. **Get Group Identifiers Request:** The learner node then sends a Get Group Identifiers Request to the teacher node to request a list of the lighting groups configured on the teacher node. The required function is:

- **eCLD_ZllUtilityCommandGetGroupIdReqCommandSend()**

- The teacher node automatically replies to the Get Group Identifiers Request by sending a Get Group Identifiers Response containing the requested information.

Learning Process

To complete the learning process, the learner node may need other information which can be acquired using commands/functions of the relevant cluster.

Parent topic:*Touchlink Commissioning Cluster*

Touchlink Commissioning events Touchlink Commissioning cluster events that result from receiving Touchlink requests and responses must be handled at the application level (while events that result from Commissioning Utility requests and responses are handled by the ZCL).

When a Touchlink request or response command (e.g. a Scan Request) is received by a node, a stack event is generated which is wrapped in a tsZCL_CallBackEvent structure. In this structure:

- eEventType field is set to E_ZCL_CBET_CLUSTER_CUSTOM
- sClusterCustomMessage field's tsZCL_ClusterCustomMessage structure is filled in by:
  - setting u16ClusterId to ZLL_CLUSTER_ID_COMMISSIONING
  - pointing pvCustomData to the payload data of the received command
    - The above structure is described in Section 6.1.15.

The payload data contains a command ID, which uses one of the enumerations listed in Section 44.6.1. The event is passed to the ZCL event handler which checks that the command ID is valid for the target endpoint. If it is valid, the user-defined callback function is invoked that was specified through the function **eZLL_RegisterCommissionEndPoint()**. The callback function can access the payload through the tsCLD_ZllCommissionCustomDataStructure structure, which is created when the above function is called.

Thus, the above user-defined callback function must be designed to handle the relevant Touchlink events:

- For a request, the callback function may need to populate a structure with the required data and send a response using the appropriate response function, e.g. by calling **eCLD_ZllCommissionCommandScanRspCommandSend()** to respond to a Scan Request.

- For a response, the callback function may just need to extract the returned data from the event.

Alternatively, the callback function may simply notify the main application of the received command and provide the payload, so that the application can process the command.

Touchlink command events The events that can be generated for Touchlink are listed and described below (the enumerations are defined in the structure teCLD_ZllCommission_Command, shown in Section 44.9.1).

Event	Description
E_CLD_COMMISSION_CMD_SCAN_REQ	A Scan Request has been received (by server)
E_CLD_COMMISSION_CMD_SCAN_RSP	A Scan Response has been received (by client)
E_CLD_COMMISSION_CMD_DEVICE_INFO_	A Device Information Request has been received (by server)
E_CLD_COMMISSION_CMD_DEVICE_INFO_	A Device Information Response has been received (by client)
E_CLD_COMMISSION_CMD_IDENTIFY_REC	An Identify Request has been received (by server)
E_CLD_COMMISSION_CMD_FACTORY_RES	A Reset To Factory New Request has been received (by server)
E_CLD_COMMISSION_CMD_NETWORK_ST	A Network Start Request has been received (by server)
E_CLD_COMMISSION_CMD_NETWORK_ST	A Network Start Response has been received (by cli-ent)
E_CLD_COMMISSION_CMD_NETWORK_JO	

ROUTER_REQ

|A Network Join Router Request has been received (by server)| |E_CLD_COMMISSION_CMD_NETWORK_JOIN_

ROUTER_RSP

|A Network Join Router Response has been received (by client)| |E_CLD_COMMISSION_CMD_NETWORK_JOIN_

END_DEVICE_REQ

|A Network Join End Device Request has been received (by server)| |E_CLD_COMMISSION_CMD_NETWORK_JOIN_

END_DEVICE_RSP

|A Network Join End Device Response has been received (by client)| |E_CLD_COMMISSION_CMD_NETWORK_UPDATE_REQ|A Network Update Request has been received (by server)|

Parent topic: Touchlink Commissioning events

Commissioning Utility Command Events The events that can be generated for the Commissioning Utility are listed and described below (the enumerations are defined in the structure teCLD_ZllUtility_Command, shown in Section 44.9.2).

Event	Description
E_CLD_UTILITY_CMD_ENDP	An Endpoint Information command has been received (by client)
E_CLD_UTILITY_CMD_GET_(	A Get Group Identifiers Request has been received (by server) or a Get Group Identifiers Response has been received (by client)
E_CLD_UTILITY_CMD_GET_I	A Get Endpoint List Request has been received (by server) or a Get Endpoint List Response has been received (by client)

Parent topic: Touchlink Commissioning events

Parent topic:*Touchlink Commissioning Cluster*

Functions The functions of the Touchlink Commissioning cluster are divided into two categories:

- Touchlink functions, detailed in Section 44.7.1
- Commissioning Utility functions, detailed in Section 44.7.2

Touchlink functions The following Touchlink functions are provided:

1. eZLL_RegisterCommissionEndPoint
2. eCLD_ZllCommissionCreateCommission
3. eCLD_ZllCommissionCommandScanReqCommandSend
4. eCLD_ZllCommissionCommandScanRspCommandSend
5. eCLD_ZllCommissionCommandDeviceInfoReqCommandSend
6. eCLD_ZllCommissionCommandDeviceInfoRspCommandSend
7. eCLD_ZllCommissionCommandDeviceIdentifyReqCommandSend
8. eCLD_ZllCommissionCommandFactoryResetReqCommandSend
9. eCLD_ZllCommissionCommandNetworkStartReqCommandSend
10. eCLD_ZllCommissionCommandNetworkStartRspCommandSend
11. eCLD_ZllCommissionCommandNetworkJoinRouterReqCommandSend
12. eCLD_ZllCommissionCommandNetworkJoinRouterRspCommandSend
13. eCLD_ZllCommissionCommandNetworkJoinEndDeviceReqCommandSend
14. eCLD_ZllCommissionCommandNetworkJoinEndDeviceRspCommandSend
15. eCLD_ZllCommissionCommandNetworkUpdateReqCommandSend

eZLL_RegisterCommissionEndPoint

```
teZCL_Status eZLL_RegisterCommissionEndPoint(
    uint8 u8EndPointIdentifier,
    tfpZCL_ZCLCallBackFunction cbCallBack,
    tsZLL_CommissionEndpoint *psDeviceInfo);
```

Description This function registers a 'commissioning' endpoint for Touchlink and creates a Touchlink Commissioning cluster instance on the endpoint.

Touchlink must have its own application (separate from the main application) on its own endpoint.

This function uses **eCLD_ZllCommissionCreateCommission()** to create the cluster instance. The type of cluster instance to be created (server or client, or both) is determined using the compile-time options in the header file **zcl_options.h** (refer to Section 44.10).

Parameters

- *u8EndPointIdentifier* Identifier of endpoint to be registered - this is an endpoint number in the range 1 to 240
- *cbCallBack* Pointer to a callback function to handle events associated with the registered endpoint
- *psDeviceInfo* Pointer to structure to be used to hold Touchlink endpoint information (see Section 44.8.1)

Returns

- E_ZCL_SUCCESS

Parent topic: Touchlink functions

eCLD_ZllCommissionCreateCommission

```
teZCL_Status eCLD_ZllCommissionCreateCommission(
    tsZCL_ClusterInstance *psClusterInstance,
    bool_t bIsServer,
    tsZCL_ClusterDefinition *psClusterDefinition,
    void *pvSharedStructPtr,
    tsZCL_AttributeStatus *psAttributeStatus,
    tsCLD_ZllCommissionCustomDataStructure
*psCustomDataStructure);
```

Description This function creates a Touchlink Commissioning cluster instance for Touchlink on the endpoint of the calling application. The type of cluster instance (server or client) to be created must be specified.

In practice, this function does not need to be called explicitly by the application, as the function **eZLL_RegisterCommissionEndPoint()** calls this function to create the cluster instance.

Parameters

- *psClusterInstance* Pointer to cluster instance structure on local endpoint
- *bIsServer* Type of cluster instance (server or client) to be created:
- TRUE - server
- FALSE - client
- *psClusterDefinition* Pointer to cluster definition structure containing information about the cluster
- *pvSharedStructPtr* Pointer to structure containing the shared storage for the cluster
- *psAttributeStatus* Pointer to a structure containing the storage for each attribute's status

- *psCustomDataStructure* Pointer to custom data to be provided to the cluster (see Section 44.8.3)

Returns

- E_ZCL_SUCCESS

Parent topic: Touchlink functions

eCLD_ZllCommissionCommandScanReqCommandSend

```
eCLD_ZllCommissionCommandScanReqCommandSend(
    ZPS_tsInterPanAddress *psDestinationAddress,
     *pu8TransactionSequenceNumber,
    tsCLD_ZllCommission_ScanReqCommandPayload
    *psPayload);
```

Description This function is used to send a Scan Request command to initiate a scan for other nodes in the local neighbourhood. The command is sent as an inter-PAN message.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *psDestinationAddress* Pointer to stucture containing PAN ID and address information for target node(s)
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the request
- *psPayload* Pointer to structure containing payload data for the Scan Request command (see Section44.8.5)

Returns

- E_ZCL_SUCCESS

Parent topic: Touchlink functions

eCLD_ZllCommissionCommandScanRspCommandSend

```
PUBLIC teZCL_Status eCLD_ZllCommissionCommandScanRspCommandSend(
    ZPS_tsInterPanAddress *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ZllCommission_ScanRspCommandPayload
*psPayload);
```

Description This function is used to send a Scan Response command containing information about the local node in reply to a received Scan Request from a remote node. The command is sent as an inter-PAN message.

A pointer must be provided to a structure containing the data to be returned.

The specified Transaction Sequence Number (TSN) of the response must match the TSN of the corresponding request, as this will allow the response to be paired with the request at the destination.

Parameters

- *psDestinationAddress* Pointer to stucture containing PAN ID and address information for target node
- *pu8TransactionSequenceNumber* Pointer to location containing the Transaction Sequence Number (TSN) of the response
- *psPayload* Pointer to structure containing payload data for the Scan Response command (see Section 44.8.6)

Returns

- E_ZCL_SUCCESS

Parent topic: Touchlink functions

eCLD_ZllCommissionCommandDeviceInfoReqCommandSend

```
teZCL_Status eCLD_ZllCommissionCommandDeviceInfoReqCommandSend(
ZPS_tsInterPanAddress *psDestinationAddress,
uint8 *pu8TransactionSequenceNumber, tsCLD_ZllCommission_DeviceInfoReqCommandPayload
↪*psPayload);
```

Description This function is used to send a Device Information Request command to obtain information about the devices on a remote node. The command is sent as an inter-PAN message.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *psDestinationAddress* Pointer to stucture containing PAN ID and address information for target node
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the request
- *psPayload* Pointer to structure containing payload data for the Device Information Request command (see Section 44.8.7)

Returns

- E_ZCL_SUCCESS

Parent topic: Touchlink functions

eCLD_ZllCommissionCommandDeviceInfoRspCommandSend

```
PUBLIC teZCL_Status eCLD_ZllCommissionCommandDeviceInfoRspCommandSend(
ZPS_tsInterPanAddress *psDestinationAddress,
uint8 *pu8TransactionSequenceNumber,
tsCLD_ZllCommission_DeviceInfoRspCommandPayload
*psPayload);
```

Description This function is used to send a Device Information Response command containing information about the devices on the local node in reply to a received Device Information Request from a remote node. The command is sent as an inter-PAN message.

A pointer must be provided to a structure containing the data to be returned.

The specified Transaction Sequence Number (TSN) of the response must match the TSN of the corresponding request, as this will allow the response to be paired with the request at the destination.

Parameters

- *psDestinationAddress* Pointer to stucture containing PAN ID and address information for target node
- *pu8TransactionSequenceNumber* Pointer to location containing the Transaction Sequence Number (TSN) of the response
- *psPayload* Pointer to structure containing payload data for the Device Information Response command (see Section 44.8.8)

Returns

- E_ZCL_SUCCESS

Parent topic: Touchlink functions

eCLD_ZllCommissionCommandDeviceIdentifyReqCommandSend

```
teZCL_Status eCLD_ZllCommissionCommandDeviceIdentifyReqCommandSend(
ZPS_tsInterPanAddress *psDestinationAddress,
uint8 *pu8TransactionSequenceNumber,
tsCLD_ZllCommission_IdentifyReqCommandPayload
*psPayload);
```

Description This function is used to send an Identify Request command to ask a remote node to identify itself by entering ‘identify mode’ (this is a visual indication, such as flashing a LED). The command is sent as an inter-PAN message.

The command payload contains a value indicating the length of time, in seconds, that the target device should remain in identify mode. It is also possible to use this command to instruct the target node to immediately exit identify mode (if it is already in this mode).

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *psDestinationAddress* Pointer to stucture containing PAN ID and address information for target node
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the request
- *psPayload* Pointer to structure containing payload data for the Identify Request command (see Section 44.8.9)

Returns

- E_ZCL_SUCCESS

Parent topic: Touchlink functions

eCLD_ZllCommissionCommandFactoryResetReqCommandSend

```
teZCL_Status eCLD_ZllCommissionCommandFactoryResetReqCommandSend(
    ZPS_tsInterPanAddress *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ZllCommission_FactoryResetReqCommandPayload
    *psPayload);
```

Description This function is used to send a Reset to Factory New Request command to ask a remote node to return to its 'factory new' state. The command is sent as an inter-PAN message.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *psDestinationAddress* Pointer to stucture containing PAN ID and address information for target node
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the request
- *psPayload* Pointer to structure containing payload data for the Reset to Factory New Request command (see Section 44.8.10)

Returns

- E_ZCL_SUCCESS

Parent topic: Touchlink functions

eCLD_ZllCommissionCommandNetworkStartReqCommandSend

```
teZCL_Status eCLD_ZllCommissionCommandNetworkStartReqCommandSend(
    ZPS_tsInterPanAddress *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ZllCommission_NetworkStartReqCommandPayload
*psPayload);
```

Description This function is used to send a Network Start Request command to create a new network with a detected Router. The command is sent as an inter-PAN message.

The function is called once the results of a Scan Request command have been received and a detected Router has been selected.

The command payload contains information about the network and the local node, as well as certain data for the target node. This payload information is detailed in Section 44.8.11.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *psDestinationAddress* Pointer to stucture containing PAN ID and address information for target node
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the request
- *psPayload* Pointer to structure containing payload data for the Network Start Request command (see Section 44.8.11)

Returns

- E_ZCL_SUCCESS

Parent topic: Touchlink functions

eCLD_ZllCommissionCommandNetworkStartRspCommandSend

```
PUBLIC teZCL_Status     eCLD_ZllCommissionCommandNetworkStartRspCommandSend(
    ZPS_tsInterPanAddress *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ZllCommission_NetworkStartRspCommandPayload
    *psPayload);
```

Description This function is used to send a Network Start Response command to confirm that the local (Router) node is ready to be the first node to join a newly created network in reply to a received Network Start Request from a remote node. The command is sent as an inter-PAN message.

A pointer must be provided to a structure containing the data to be returned.

The specified Transaction Sequence Number (TSN) of the response must match the TSN of the corresponding request, as this will allow the response to be paired with the request at the destination.

Parameters

- *psDestinationAddress* Pointer to stucture containing PAN ID and address information for target node
- *pu8TransactionSequenceNumber* Pointer to location containing the Transaction Sequence Number (TSN) of the response
- *psPayload* Pointer to structure containing payload data for the Network Start Response command (see Section 44.8.12)

Returns

- E_ZCL_SUCCESS

Parent topic: Touchlink functions

eCLD_ZllCommissionCommandNetworkJoinRouterReqCommandSend

```
teZCL_Status eCLD_ZllCommissionCommandNetworkJoinRouterReqCommandSend(
    ZPS_tsInterPanAddress *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ZllCommission_NetworkJoinRouterReqCommandPayload
    *psPayload);
```

Description This function is used to send a Network Join Router Request command to allow a detected Router to join the created network. The command is sent as an inter-PAN message.

The function can be called once a network has been created. The target Router is distinct from the Router that was included when network was created.

The command payload contains information about the network and the local node, as well as certain data for the target node. This payload information is detailed in Section 44.8.13.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *psDestinationAddress* Pointer to stucture containing PAN ID and address information for target node
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the request
- *psPayload* Pointer to structure containing payload data for the Network Join Router Request command (see Section 44.8.13)

Returns

- E_ZCL_SUCCESS

Parent topic: Touchlink functions

eCLD_ZllCommissionCommandNetworkJoinRouterRspCommandSend

```
PUBLIC teZCL_Status eCLD_ZllCommissionCommandNetworkJoinRouterRspCommandSend(
    ZPS_tsInterPanAddress psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ZllCommission_NetworkJoinRouterRspCommandPayload
    *psPayload);
```

Description This function is used to send a Network Join Router Response command to confirm that the local (Router) node is ready to join a network in reply to a received Network Join Router Request from a remote node. The command is sent as an inter-PAN message.

A pointer must be provided to a structure containing the data to be returned.

The specified Transaction Sequence Number (TSN) of the response must match the TSN of the corresponding request, as this will allow the response to be paired with the request at the destination.

Parameters

- *psDestinationAddress* Pointer to stucture containing PAN ID and address information for target node
- *psDestinationAddress* Pointer to location containing the Transaction Sequence Number (TSN) of the response
- **psPayload* Pointer to structure containing payload data for the Network Join Router Response command (see Section 44.8.14)

Returns

- E_ZCL_SUCCESS

Parent topic: Touchlink functions

eCLD_ZllCommissionCommandNetworkJoinEndDeviceReqCommandSend

```
teZCL_Status    eCLD_ZllCommissionCommandNetworkJoinEndDeviceReqCommandSend(
    ZPS_tsInterPanAddress *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_ZllCommission_NetworkJoinEndDeviceReqCommandPayload
*psPayload);
```

Description This function is used to send a Network Join End Device Request command to allow a detected End Device to join the created network. The command is sent as an inter-PAN message.

The function can be called once a network has been created.

The command payload contains information about the network and the local node, as well as certain data for the target node. This data includes a range of network addresses and a range of group IDs from which the target End Device can assign values to the other nodes - in this case, the End Device would typically be a remote control unit. This payload information is detailed in Section 44.8.15.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *psDestinationAddress*: Pointer to stucture containing PAN ID and address information for target node
- *pu8TransactionSequenceNumber*: Pointer to a location to store the Transaction Sequence Number (TSN) of the request

- *psPayload*: Pointer to structure containing payload data for the Network Join End Device Request command (see Section 44.8.15)

Returns

- E_ZCL_SUCCESS

Parent topic: Touchlink functions

eCLD_ZllCommissionCommandNetworkJoinEndDeviceRspCommandSend

```
PUBLIC teZCL_Status eCLD_ZllCommissionCommandNetworkJoinEndDeviceRspCommandSend(
ZPS_tsInterPanAddress *psDestinationAddress,
uint8 *pu8TransactionSequenceNumber,
tsCLD_ZllCommission_NetworkJoinEndDeviceRspCommandPayload
*psPayload);
```

Description This function is used to send a Network Join End Device Response command to confirm that the local (End Device) node is ready to join a network in reply to a received Network Join End Device Request from a remote node. The command is sent as an inter-PAN message.

A pointer must be provided to a structure containing the data to be returned.

The specified Transaction Sequence Number (TSN) of the response must match the TSN of the corresponding request, as this will allow the response to be paired with the request at the destination.

Parameters

- *psDestinationAddress* Pointer to stucture containing PAN ID and address information for target node
- *pu8TransactionSequenceNumber* Pointer to location containing the Transaction Sequence Number (TSN) of the response
- *psPayload* Pointer to structure containing payload data for the Network Join End Device Response command (see Section 44.8.16)

Returns

- E_ZCL_SUCCESS

Parent topic: Touchlink functions

eCLD_ZllCommissionCommandNetworkUpdateReqCommandSend

```
teZCL_Status eCLD_ZllCommissionCommandNetworkUpdateReqCommandSend(
        ZPS_tsInterPanAddress *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        tsCLD_ZllCommission_NetworkUpdateReqCommandPayload
        *psPayload);
```

Description This function is used to send a Network Update Request command to bring a node that has missed a network update back into the network. The command is sent as an inter-PAN message.

The command payload contains information about the network, including the current value of the Network Update Identifier. This identifier takes a value in the range 0x00 to 0xFF and is incremented when a network update has occurred (the value wraps around at 0xFF). Thus, if this value in the payload is more recent than the value of this identifier held by the target node, the node should update its network settings using the values in the rest of the payload. The payload information is detailed in Section 44.8.17.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *psDestinationAddress* Pointer to stucture containing PAN ID and address information for target node
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the request
- *psPayload* Pointer to structure containing payload data for the Network Update Request command (see Section 44.8.17)

Returns

- E_ZCL_SUCCESS

Parent topic: Touchlink functions

Parent topic: Functions

Commissioning Utility functions The following Commissioning Utility functions are provided:

1. eCLD_ZllUtilityCreateUtility
2. eCLD_ZllUtilityCommandEndpointInformationCommandSend
3. eCLD_ZllUtilityCommandGetGroupIdReqCommandSend
4. eCLD_ZllUtilityCommandGetGroupIdRspCommandSend
5. eCLD_ZllUtilityCommandGetEndpointListReqCommandSend
6. eCLD_ZllUtilityCommandGetEndpointListRspCommandSend
7. eCLD_ZllUtilityCommandHandler

eCLD_ZllUtilityCreateUtility

```
teZCL_Status eCLD_ZllUtilityCreateUtility(
        tsZCL_ClusterInstance *psClusterInstance,
        bool_t bIsServer,
        tsZCL_ClusterDefinition *psClusterDefinition,
        void *pvSharedStructPtr,
        tsZCL_AttributeStatus psAttributeStatus,
        tsCLD_ZllUtilityCustomDataStructure
    *psCustomDataStructure);
```

Description This function creates a Touchlink Commissioning cluster instance for the Commissioning Utility. The cluster instance is created on the endpoint of the calling application, which should be the main application on the node. The type of cluster instance (server or client) to be created must be specified.

Parameters

- *psClusterInstance* Pointer to cluster instance structure on local endpoint
- *bIsServer* Type of cluster instance (server or client) to be created:
- TRUE - server
- FALSE - client
- *psClusterDefinition* Pointer to cluster definition structure containing information about the cluster
- *pvSharedStructPtr* Pointer to structure containing the shared storage for the cluster
- *psAttributeStatus* Pointer to a structure containing the storage for each attribute's status
- *psCustomDataStructure* Pointer to custom data to be provided to the cluster (see Section 44.8.20)

Returns

- E_ZCL_SUCCESS

Parent topic: Commissioning Utility functions

eCLD_ZllUtilityCommandEndpointInformationCommandSend

```
teZCL_Status eCLD_ZllUtilityCommandEndpointInformationCommandSend(
        uint8 u8SrcEndpoint,
        uint8 u8DstEndpoint,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        tsCLD_ZllUtility_EndpointInformationCommandPayload
*psPayload);
```

Description This function is used to send an Endpoint Information command to provide a remote endpoint with general information about the local endpoint (this may prompt the remote endpoint to request further information about the local endpoint). The function would typically be used to send local endpoint information from a 'teacher' node to a 'learner' node, in order to facilitate two-way communication between the Commissioning Utilities on the two nodes.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the command. The TSN in the response is set to match the specified TSN, allowing an incoming response to be paired with the original command. This is useful when sending more than one command to the same destination endpoint.

Parameters

- *u8SrcEndpoint* Number of local endpoint (1-240)
- *u8DstEndpoint* Number of destination endpoint (1-240)
- *psDestinationAddress* Pointer to stucture containing address information for target node

- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the command
- *psPayload* Pointer to structure to contain payload data for the Endpoint Information command (see Section 44.8.20)

Returns

- E_ZCL_SUCCESS

Parent topic: Commissioning Utility functions

eCLD_ZllUtilityCommandGetGroupIdReqCommandSend

```
teZCL_Status eCLD_ZllUtilityCommandGetGroupIdReqCommandSend(
        uint8 u8Srcendpoint,
        uint8 u8DstEndpoint,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        uint8 u8StartIndex);
```

Description This function is used to send a Get Group Identifiers Request command to obtain information about the groups (of lights) that have been configured on a remote endpoint. The function would typically be used on a 'learner' node to request the groups that have been configured on a 'teacher' node.

The first group from the groups list to be included in the returned information must be specified in terms of an index.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SrcEndpoint* Number of local endpoint (1-240)
- *u8DstEndpoint* Number of destination endpoint (1-240)
- *psDestinationAddress* Pointer to stucture containing address information for target node
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the request
- *u8StartIndex* Index in group list of the first group to include in the returned information

Returns

- E_ZCL_SUCCESS

Parent topic: Commissioning Utility functions

eCLD_ZllUtilityCommandGetGroupIdRspCommandSend

```
PUBLIC teZCL_Status  eCLD_ZllUtilityCommandGetGroupIdRspCommandSend(
        uint8 u8SrcEndpoint,
        uint8 u8DstEndpoint,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        uint8 u8StartIndex);
```

Description This function is used to send a Get Group Identifiers Response command containing information about the groups (of lights) that have been configured on the local endpoint. The function would typically be used on a 'teacher' node to respond to a Get Group Identifiers Request from a 'learner' node.

The first group from the groups list to be included in the returned information must be specified in terms of an index. The returned information includes this index, the number of (consecutive) groups included and the identifier of each group.

The specified Transaction Sequence Number (TSN) of the response must match the TSN of the corresponding request, as this will allow the response to be paired with the request at the destination.

Parameters

- *u8SrcEndpoint* Number of local endpoint (1-240)
- *u8DstEndpoint* Number of destination endpoint (1-240)
- *psDestinationAddress* Pointer to stucture containing address information for target node
- *pu8TransactionSequenceNumber* Pointer to location containing the Transaction Sequence Number (TSN) of the response
- *u8StartIndex* Index in group list of the first group to include in the returned information

Returns

- E_ZCL_SUCCESS

Parent topic: Commissioning Utility functions

eCLD_ZllUtilityCommandGetEndpointListReqCommandSend

```
teZCL_Status eCLD_ZllUtilityCommandGetEndpointListReqCommandSend(
        uint8 u8SrcEndpoint,
        uint8 u8DstEndpoint,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        uint8 u8StartIndex);
```

Description This function is used to send a Get Endpoint List Request command to obtain information about controlled endpoints. The function would typically be used on a 'learner' node to request the remote endpoints that a 'teacher' node controls.

The first endpoint from the endpoints list to be included in the returned information must be specified in terms of an index.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing

an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SrcEndpoint* Number of local endpoint (1-240)
- *u8DstEndpoint* Number of destination endpoint (1-240)
- *psDestinationAddress* Pointer to stucture containing address information for target node
- *pu8TransactionSequenceNumber* Pointer to a location to store the Transaction Sequence Number (TSN) of the request
- *u8StartIndex* Index in endpoint list of the first endpoint to include in the returned information

Returns

- E_ZCL_SUCCESS

Parent topic: Commissioning Utility functions

eCLD_ZllUtilityCommandGetEndpointListRspCommandSend

```
PUBLIC teZCL_Status eCLD_ZllUtilityCommandGetEndpointListRspCommandSend(
        uint8 u8SrcEndpoint,
        uint8 u8DstEndpoint,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        uint8 u8StartIndex);
```

Description This function is used to send a Get Endpoint List Response command containing information about controlled endpoints. The function would typically be used on a 'teacher' node to respond to a Get Endpoint List Request from a 'learner' node.

The first endpoint from the endpoints list to be included in the returned information must be specified in terms of an index. The returned information will include this index, the number of (consecutive) endpoints included and the information about each endpoint (including endpoint number, identifier of resident ZigBee device and version of this device).

The specified Transaction Sequence Number (TSN) of the response must match the TSN of the corresponding request, as this will allow the response to be paired with the request at the destination.

Parameters

- *u8SrcEndpoint* Number of local endpoint (1-240)
- *u8DstEndpoint* Number of destination endpoint (1-240)
- *psDestinationAddress* Pointer to stucture containing address information for target node
- *pu8TransactionSequenceNumber* Pointer to location containing the Transaction Sequence Number (TSN) of the response
- *u8StartIndex* Index in endpoint list of the first endpoint to include in the returned information

Returns

- E_ZCL_SUCCESS

Parent topic: Commissioning Utility functions

eCLD_ZllUtilityCommandHandler

```
teZCL_Status eCLD_ZllUtilityCommandHandler(
    ZPS_tsAfEvent *pZPSevent,
    tsZCL_EndPointDefinition *psEndPointDefinition,
    tsZCL_ClusterInstance *psClusterInstance);
```

Description This function parses a ZigBee PRO event and invokes the user-defined callback function that has been registered for the device (using the relevant endpoint registration function).

The registered user-defined callback function must be designed to handle events associated with the Commissioning Utility.

Parameters

- *pZPSevent* Pointer to received ZigBee PRO event
- *psEndPointDefinition* Pointer to structure which defines endpoint on which the Commissioning Utility resides
- *psClusterInstance* Pointer to Touchlink Commissioning cluster instance structure

Returns

- E_ZCL_SUCCESS

Parent topic: Commissioning Utility functions

Parent topic: Functions

Parent topic:*Touchlink Commissioning Cluster*

Structures This section details the structures used in the Touchlink Commissioning cluster (both Touchlink and Commissioning Utility parts).

tsZLL_CommissionEndpoint This structure is used to hold endpoint information for a Touchlink application.

```
typedef struct
{
tsZCL_EndPointDefinition sEndPoint;
tsZLL_CommissionEndpointClusterInstances sClusterInstance;
#if (defined CLD_ZLL_COMMISSION) && (defined ZLL_COMMISSION_SERVER)
    tsCLD_ZllCommission sZllCommissionServerCluster;
    tsCLD_ZllCommissionCustomDataStructure
              sZllCommissionServerCustomDataStructure;
#endif
#if (defined CLD_ZLL_COMMISSION) && (defined ZLL_COMMISSION_CLIENT)
    tsCLD_ZllCommission sZllCommissionClientCluster;
    tsCLD_ZllCommissionCustomDataStructure
             sZllCommissionClientCustomDataStructure;
```

(continues on next page)

(continued from previous page)

```
#endif
} tsZLL_CommissionEndpoint;
```

where:

- sEndPoint is a ZCL structure containing information about the endpoint (refer to Section 6.1.1).
- sClusterInstance is a structure containing information about the Touchlink Commissioning cluster instance on the endpoint (see Section 44.8.2).
- For a Touchlink server, the following fields are used:
  - sZllCommissionServerCluster is the Touchlink Commissioning cluster structure (which contains no attributes).
  - sZllCommissionServerCustomDataStructure is a structure containing custom data for the cluster server (see Section 44.8.3).
- For a Touchlink client, the following fields are used:
  - sZllCommissionClientClusteris the Touchlink Commissioning cluster structure (which contains no attributes).
  - sZllCommissionClientCustomDataStructure is a structure containing custom data for the cluster client (see Section 44.8.3).

Parent topic: Structures

tsZLL_CommissionEndpointClusterInstances This structure holds information about the Touchlink Commissioning cluster instance on an endpoint.

```
typedef struct PACK
{
#if (defined CLD_ZLL_COMMISSION) && (defined ZLL_COMMISSION_SERVER)
   tsZCL_ClusterInstance sZllCommissionServer;
#endif
#if (defined CLD_ZLL_COMMISSION) && (defined ZLL_COMMISSION_CLIENT)
   tsZCL_ClusterInstance sZllCommissionClient;
#endif
} tsZLL_CommissionEndpointClusterInstances;
```

where:

- s``ZllCommissionServer is a ZCL structure containing information about the Touchlink Commissioning cluster server instance (refer to Section 6.1.16).
- s``ZllCommissionClient is a ZCL structure containing information about the Touchlink Commissioning cluster client instance (refer to Section 6.1.16).

Parent topic: Structures

tsCLD_ZllCommissionCustomDataStructure This structure is used to hold the data for a Touchlink command received by a node.

```
typedef struct
{
   tsZCL_ReceiveEventAddressInterPan    sRxInterPanAddr;
   tsZCL_CallBackEvent                  sCustomCallBackEvent;
   tsCLD_ZllCommissionCallBackMessage   sCallBackMessage;
```

(continues on next page)

(continued from previous page)

```
} tsCLD_ZllCommissionCustomDataStructure;
```

where:

- RxInterPanAddr is a ZCL structure containing the Inter-PAN addresses of the source and destination nodes of the command.
- sCustomCallBackEvent is the ZCL event structure for the command.
- sCallBackMessage is a structure containing the command ID and payload (see Section 44.8.4).

Parent topic: Structures

tsCLD_ZllCommissionCallBackMessage This structure contains the command ID and payload for a received Touchlink command.

```
typedef struct
{
    uint8   u8CommandId;
    union
    {
        tsCLD_ZllCommission_ScanReqCommandPayload
                                *psScanReqPayload;
        tsCLD_ZllCommission_ScanRspCommandPayload
                                *psScanRspPayload;
        tsCLD_ZllCommission_IdentifyReqCommandPayload
                                *psIdentifyReqPayload;
        tsCLD_ZllCommission_DeviceInfoReqCommandPayload
                                *psDeviceInfoReqPayload;
        tsCLD_ZllCommission_DeviceInfoRspCommandPayload
                                *psDeviceInfoRspPayload;
        tsCLD_ZllCommission_FactoryResetReqCommandPayload
                                *psFactoryResetPayload;
        tsCLD_ZllCommission_NetworkStartReqCommandPayload
                                *psNwkStartReqPayload;
        tsCLD_ZllCommission_NetworkStartRspCommandPayload
                                *psNwkStartRspPayload;
        tsCLD_ZllCommission_NetworkJoinRouterReqCommandPayload
                                *psNwkJoinRouterReqPayload;
        tsCLD_ZllCommission_NetworkJoinRouterRspCommandPayload
                                *psNwkJoinRouterRspPayload;
        tsCLD_ZllCommission_NetworkJoinEndDeviceReqCommandPayload
                                *psNwkJoinEndDeviceReqPayload;
        tsCLD_ZllCommission_NetworkJoinEndDeviceRspCommandPayload
                                *psNwkJoinEndDeviceRspPayload;
        tsCLD_ZllCommission_NetworkUpdateReqCommandPayload
                                *psNwkUpdateReqPayload;
    } uMessage;
} tsCLD_ZllCommissionCallBackMessage;
```

where:

- u8CommandId is the command ID - enumerations are provided, as detailed in Section 44.6.1.
- uMessage contains the payload of the command, where the structure used depends on the command ID (the structures are detailed in the sections below).

Parent topic: Structures

tsCLD_ZllCommission_ScanReqCommandPayload This structure is used to hold the payload data for a Touchlink Scan Request command.

```
typedef struct
{
    uint32 u32TransactionId;
    uint8  u8ZigbeeInfo;
    uint8  u8ZllInfo;
} tsCLD_ZllCommission_ScanReqCommandPayload;
```

where:

- u32TransactionId is the 32-bit Inter-PAN Transaction Identifier of the request. This is a random number generated and inserted automatically.
- u8ZigbeeInfo is a bitmap of ZigBee information which indicates the ZigBee device type of the sending node and whether the radio receiver remains on when the node is idle. This information is inserted by the ZigBee stack.
- u8ZllInfo is a bitmap indicating properties of the sending node, including whether the node is factory new, whether the node is able to assign addresses to other nodes and whether the node is able to initiate a link operation (supports Touchlink Commissioning cluster on the client side). This information is inserted automatically.

Parent topic: Structures

tsCLD_ZllCommission_ScanRspCommandPayload This structure is used to hold the payload data for a Touchlink Scan Response command.

```
typedef struct
{
    uint32  u32TransactionId;
    uint8   u8RSSICorrection;
    uint8   u8ZigbeeInfo;
    uint8   u8ZllInfo;
    uint16  u16KeyMask;
    uint32  u32ResponseId;
    uint64  u64ExtPanId;
    uint8   u8NwkUpdateId;
    uint8   u8LogicalChannel;
    uint16  u16PanId;
    uint16  u16NwkAddr;
    uint8   u8NumberSubDevices;
    uint8   u8TotalGroupIds;
    uint8   u8Endpoint;
    uint16  u16ProfileId;
    uint16  u16DeviceId;
    uint8   u8Version;
    uint8   u8GroupIdCount;
} tsCLD_ZllCommission_ScanRspCommandPayload;
```

where:

- u32TransactionId is the 32-bit Inter-PAN Transaction Identifier of the response, which must take the same value as the identifier in the corresponding request.
- u8RSSICorrection is the 8-bit RSSI correction offset for the node, in the range 0x00 to 0x20.
- u8ZigbeeInfo is an 8-bit field containing the following ZigBee-related information:
  - Bits 1-0: Node type (00 - Co-ordinator, 01 - Router, 10 - End Device)
  - Bit 2: Rx on when idle (1 - On, 0 - Off)

  - Bits 7-3: Reserved
- u8ZllInfo is an 8-bit field containing the following information:
  - Bit 0: Factory new (1 - Yes, 0 - No)
  - Bit 1: Address assignment capability (1 - Yes, 0 - No)
  - Bits 3-2: Reserved
  - Bit 4: Touchlink initiator (1 - Yes, 0 - No)
  - Bit 5: Touchlink priority request (1 - Yes, 0 - No)
  - Bits 7-6: Reserved
- u16KeyMask is a 16-bit bitmap indicating which link key is installed on the node - only one bit should be set to '1', corresponding to the key that is in use. The possible values and keys are:
  - 0x0001 (bit 0 set): Development key (defined by developer for use during application development)
  - 0x0010 (bit 4 set): Master key (obtained from the ZigBee Alliance after successful certification and agreement with the terms of the 'ZLL Security Key Licence and Confidentialty Agreement')
  - 0x8000 (bit 15 set): Certification key (defined in the ZLL Specification for use during development and during certification at test houses)
- u``32ResponseId is a 32-bit random identifier for the response, used during network key transfer.
- u64ExtPanId is the 64-bit Extended PAN ID of a network to which the node already belongs, if any (a zero value indicates no network membership).
- u8NwkUpdateId is the current value of the Network Update Identifier on the node (see Section 44.4.3).
- u8LogicalChannel is the number of the IEEE 802.15.4 radio channel used by a network to which the node already belongs, if any (a zero value indicates no network membership and therefore that no particular channel is used).
- u16PanId is the 16-bit PAN ID of a network to which the node already belongs, if any (a zero value indicates no network membership).
- u16NwkAddr is the 16-bit network address currently assigned to the node (the value 0xFFFF indicates that the node is 'factory new' and has no assigned network address).
- u8NumberSubDevices is the number of ZigBee devices on the node.
- u8TotalGroupIds is the total number of groups (of lights) supported on the node (across all devices).
- u8Endpoint is number of the endpoint (in the range 1-240) on which the ZigBee device is resident (this field is only used when there is only one ZigBee device on the node).
- u16ProfileId is the 16-bit identifier of the ZigBee application profile that is supported by the device (this field is only used when there is only one ZigBee device on the node).
- u16DeviceId is the 16-bit Device Identifier supported by the device (this field is only used when there is only one ZigBee device on the node).
- u8Version is an 8-bit version number for the device - the four least significant bits are from the Application Device Version field of the appropriate Simple Descriptor and the four most significant bits are zero (this field is only used when there is only one ZigBee device on the node).
- u8GroupIdCount is the number of groups (of lights) supported by the device (this field is only used when there is only one ZigBee device on the node).

Parent topic: Structures

tsCLD_ZllCommission_DeviceInfoReqCommandPayload This structure is used to hold the payload data for a Touchlink Device Information Request command.

```
typedef struct
{
    uint32 u32TransactionId;
    uint8  u8StartIndex;
} tsCLD_ZllCommission_DeviceInfoReqCommandPayload;
```

where:

- u32TransactionId is the 32-bit Inter-PAN Transaction Identifier of the request. This is a random number generated and inserted automatically.
- u8StartIndex specifies the index (starting from 0) of the first entry in the device table from which device information should be obtained.

Parent topic: Structures

tsCLD_ZllCommission_DeviceInfoRspCommandPayload This structure is used to hold the payload data for a Touchlink Device Information Response command.

```
typedef struct
{
    uint32  u32TransactionId;
    uint8   u8NumberSubDevices;
    uint8   u8StartIndex;
    uint8   u8DeviceInfoRecordCount;
    tsCLD_ZllDeviceRecord asDeviceRecords[ZLL_MAX_DEVICE_RECORDS];
} tsCLD_ZllCommission_DeviceInfoRspCommandPayload;
```

where:

- u32TransactionId is the 32-bit Inter-PAN Transaction Identifier of the response, which must take the same value as the identifier in the corresponding request.
- u8NumberSubDevices is the number of ZigBee devices on the node (as reported in the Scan Response).
- u8StartIndex is the index (starting from 0) of the first entry in the device table from which device information has been obtained (this value should be as specified in the corresponding request).
- u8DeviceInfoRecordCount indicates the number of device information records included in the response (in the range 0 to 5).
- asDeviceRecords[] is an array, where each array element is a tsCLD_ZllDeviceRecord structure containing a device information record for one ZigBee device on the node.

Parent topic: Structures

tsCLD_ZllCommission_IdentifyReqCommandPayload This structure is used to hold the payload data for a Touchlink Identify Request command.

```
typedef struct
{
    uint32  u32TransactionId;
```

(continues on next page)

(continued from previous page)

```
    uint16  u16Duration;
} tsCLD_ZllCommission_IdentifyReqCommandPayload;
```

where:

- u32TransactionId is the 32-bit Inter-PAN Transaction Identifier of the request. This is a random number generated and inserted automatically.
- u16Duration specifies the length of time (in seconds) that the target node is to remain in identify mode. The possible values are:
  - 0x0000: Exit identify mode immediately
  - 0x0001–0xFFFE: Number of seconds to remain in identify mode
  - 0xFFFF: Remain in identify mode for the default time for the target node
    - If the target node is unable to provide accurate timings, it will attempt to remain in identify mode for as close to the requested time as possible

Parent topic: Structures

tsCLD_ZllCommission_FactoryResetReqCommandPayload This structure is used to hold the payload data for a Touchlink Reset to Factory New Request command.

```
typedef struct
{
    uint32 u32TransactionId;
} tsCLD_ZllCommission_FactoryResetReqCommandPayload;
```

where u32TransactionId is the 32-bit Inter-PAN Transaction Identifier of the request. This is a random number generated and inserted automatically.

Parent topic: Structures

tsCLD_ZllCommission_NetworkStartReqCommandPayload This structure is used to hold the payload data for a Touchlink Network Start Request command.

```
typedef struct
{
    uint32  u32TransactionId;
    uint64  u64ExtPanId;
    uint8   u8KeyIndex;
    uint8   au8NwkKey[16];
    uint8   u8LogicalChannel;
    uint16  u16PanId;
    uint16  u16NwkAddr;
    uint16  u16GroupIdBegin;
    uint16  u16GroupIdEnd;
    uint16  u16FreeNwkAddrBegin;
    uint16  u16FreeNwkAddrEnd;
    uint16  u16FreeGroupIdBegin;
    uint16  u16FreeGroupIdEnd;
    uint64  u64InitiatorIEEEAddr;
    uint16  u16InitiatorNwkAddr;
} tsCLD_ZllCommission_NetworkStartReqCommandPayload;
```

where:

- u32TransactionId is the 32-bit Inter-PAN Transaction Identifier of the request. This is a random number generated and inserted automatically.
- u64ExtPanId is the Extended PAN ID (EPID) of the new network (if set to zero, the target node will choose the EPID).
- u8KeyIndex is a value indicating the type of security key used to encrypt the randomly generated network key in au8NwkKey. The valid values are as follows (all other values are reserved for future use):
  - 0: Development key, used during development before ZigBee certification
  - 4: Master key, used after successful ZigBee certification
  - 15: Certification key, used during ZigBee certification testing
- au8NwkKey[16] is the 128-bit randomly generated network key encrypted using the key specified in u8KeyIndex.
- u8LogicalChannel is the number of the IEEE 802.15.4 radio channel to be used by the network (if set to zero, the target node will choose the channel).
- u16PanId is the PAN ID of the new network (if set to zero, the target node will choose the PAN ID).
- u16NwkAddr is the 16-bit network (short) address assigned to the target node
- u16GroupIdBegin is the start value of the range of group identifiers that the target node can use for its own endpoints (if set to zero, no range of group identifiers has been allocated).
- u16GroupIdEnd is the end value of the range of group identifiers that the target node can use for its own endpoints (if set to zero, no range of group identifiers has been allocated).
- u16FreeNwkAddrBegin is the start address of the range of network addresses that the target node can assign to other nodes (if set to zero, no range of network addresses has been allocated).
- u16FreeNwkAddrEnd is the end address of the range of network addresses that the target node can assign to other nodes (if set to zero, no range of network addresses has been allocated).
- u16FreeGroupIdBegin is the start value of the range of free group identifiers that the target node can assign to other nodes (if set to zero, no range of free group identifiers has been allocated).
- u16FreeGroupIdEnd is the end value of the range of free group identifiers that the target node can assign to other nodes (if set to zero, no range of free group identifiers has been allocated).
- u64InitiatorIEEEAddr is the IEEE (MAC) address of the local node (network initiator)
- u16InitiatorNwkAddr is the network (short) address of the local node (network initiator)

Parent topic: Structures

tsCLD_ZllCommission_NetworkStartRspCommandPayload This structure is used to hold the payload data for a Touchlink Network Start Response command.

```
typedef struct
{
    uint32  u32TransactionId;
    uint8   u8Status;
    uint64  u64ExtPanId;
    uint8   u8NwkUpdateId;
    uint8   u8LogicalChannel;
    uint16  u16PanId;
```

(continues on next page)

(continued from previous page)

```
} tsCLD_ZllCommission_NetworkStartRspCommandPayload;
```

where:

- u32TransactionId is the 32-bit Inter-PAN Transaction Identifier of the response, which must take the same value as the identifier in the corresponding request.
- u8Status indicates the outcome of the corresponding Network Start Request: 0x00 for success, 0x01 for failure.
- u64ExtPanId is the Extended PAN ID (EPID) of the new network (this will be the value specified in the corresponding request or a value chosen by the local node).
- u8NwkUpdateId is the current value of the Network Update Identifier, which will be set to zero for a new network (see Section 44.4.3).
- u8LogicalChannel is the number of the IEEE 802.15.4 radio channel to be used by the network (this will be the value specified in the corresponding request or a value chosen by the local node).
- u16PanId is the PAN ID of the new network (this will be the value specified in the corresponding request or a value chosen by the local node).

Parent topic: Structures

tsCLD_ZllCommission_NetworkJoinRouterReqCommandPayload This structure is used to hold the payload data for a Touchlink Network Join Router Request command.

```
typedef struct
{
    uint32  u32TransactionId;
    uint64  u64ExtPanId;
    uint8   u8KeyIndex;
    uint8   au8NwkKey[16];
    uint8   u8NwkUpdateId;
    uint8   u8LogicalChannel;
    uint16  u16PanId;
    uint16  u16NwkAddr;
    uint16  u16GroupIdBegin;
    uint16  u16GroupIdEnd;
    uint16  u16FreeNwkAddrBegin;
    uint16  u16FreeNwkAddrEnd;
    uint16  u16FreeGroupIdBegin;
    uint16  u16FreeGroupIdEnd;
} tsCLD_ZllCommission_NetworkJoinRouterReqCommandPayload;
```

where:

- u32TransactionId is the 32-bit Inter-PAN Transaction Identifier of the request. This is a random number generated and inserted automatically.
- u64ExtPanId is the Extended PAN ID (EPID) of the network.
- u8KeyIndex is a value indicating the type of security key used to encrypt the network key in au8NwkKey. The valid values are as follows (all other values are reserved for future use):
  - 0: Development key, used during development before ZigBee certification
  - 4: Master key, used after successful ZigBee certification
  - 15: Certification key, used during ZigBee certification testing
- au8NwkKey[16] is the 128-bit network key encrypted using the key specified in u8KeyIndex.

- u8NwkUpdateId is the current value of the Network Update Identifier. This identifier takes a value in the range 0x00 to 0xFF and is incremented when a network update has occurred which requires the network settings on the nodes to be changed.
- u8LogicalChannel is the number of the IEEE 802.15.4 radio channel used by the network.
- u16PanId is the PAN ID of the network
- u16NwkAddr is the 16-bit network (short) address assigned to the target node
- u16GroupIdBegin is the start value of the range of group identifiers that the target node can use for its own endpoints (if set to zero, no range of group identifiers has been allocated).
- u16GroupIdEnd is the end value of the range of group identifiers that the target node can use for its own endpoints (if set to zero, no range of group identifiers has been allocated).
- u16FreeNwkAddrBegin is the start address of the range of network addresses that the target node can assign to other nodes (if set to zero, no range of network addresses has been allocated).
- u16FreeNwkAddrEnd is the end address of the range of network addresses that the target node can assign to other nodes (if set to zero, no range of network addresses has been allocated).
- u16FreeGroupIdBegin is the start value of the range of free group identifiers that the target node can assign to other nodes (if set to zero, no range of free group identifiers has been allocated).
- u16FreeGroupIdEnd is the end value of the range of free group identifiers that the target node can assign to other nodes (if set to zero, no range of free group identifiers has been allocated).

    uint32 u32TransactionId;
    uint8   u8Status;
} tsCLD_ZllCommission_NetworkJoinEndDeviceRspCommandPayload;
```

where:

- u32TransactionId is the 32-bit Inter-PAN Transaction Identifier of the response, which must take the same value as the identifier in the corresponding request.
- u8Status indicates the outcome of the corresponding Network Join End Device Request: 0x00 for success, 0x01 for failure.

Parent topic: Structures

tsCLD_ZllCommission_NetworkUpdateReqCommandPayload This structure is used to hold the payload data for a Touchlink Network Update Request command.

```
typedef struct
{
 uint32  u32TransactionId;
 uint64  u64ExtPanId;
 uint8u8NwkUpdateId;
 uint8u8LogicalChannel;
 uint16  u16PanId;
 uint16  u16NwkAddr;
} tsCLD_ZllCommission_NetworkUpdateReqCommandPayload;
```

where:

- u32TransactionId is the 32-bit Inter-PAN Transaction Identifier of the request. This is a random number generated and inserted automatically.
- u64ExtPanId is the Extended PAN ID (EPID) of the network.
- u8NwkUpdateId is the current value of the Network Update Identifier (see Section 44.4.3).
- u8LogicalChannel is the number of the IEEE 802.15.4 radio channel used by the network.
- u16PanId is the PAN ID of the network.
- u16NwkAddr is the 16-bit network (short) address assigned to the target node.

Parent topic: Structures

tsCLD_ZllUtilityCustomDataStructure This structure is used to hold custom data for a Commissioning Utility instance of the Touchlink Commissioning cluster.

```
typedef struct
{
 tsZCL_ReceiveEventAddress sRxAddr;
 tsZCL_CallBackEvent sCustomCallBackEvent;
 tsCLD_ZllUtilityCallBackMessage sCallBackMessage;
} tsCLD_ZllUtilityCustomDataStructure;
```

where:

- sRxAddr is a ZCL structure containing the destination address of the command.
- sCustomCallBackEvent is the ZCL event structure for the command.
- sCallBackMessage is a structure containing the command ID and payload (see Section 44.8.19).

Parent topic: Structures

tsCLD_ZllUtilityCallBackMessage This structure contains the command ID and payload for a received Commissioning Utility command.

```
typedef struct
{
 uint8u8CommandId;
 union
 {
  tsCLD_ZllUtility_EndpointInformationCommandPayload
 *psEndpointInfoPayload;
  tsCLD_ZllUtility_GetGroupIdReqCommandPayload
 *psGetGroupIdReqPayload;
  tsCLD_ZllUtility_GetGroupIdRspCommandPayload
 *psGetGroupIdRspPayload;
  tsCLD_ZllUtility_GetEndpointListReqCommandPayload
 *psGetEndpointlistReqPayload;
  tsCLD_ZllUtility_GetEndpointListRspCommandPayload
 *psGetEndpointListRspPayload;
 } uMessage;
} tsCLD_ZllUtilityCallBackMessage;
```

where:

- u8CommandId is the command ID - enumerations are provided, as detailed in Section 44.6.2.
- uMessage contains the payload of the command, where the structure used depends on the command ID (the structures are detailed in the sections below).

Parent topic: Structures

tsCLD_ZllUtility_EndpointInformationCommandPayload This structure is used to hold the payload data for a Commissioning Utility Endpoint Information command.

```
typedef struct
{
 uint64  u64IEEEAddr;
 uint16  u16NwkAddr;
 uint8u8Endpoint;
 uint16  u16ProfileID;
 uint16  u16DeviceID;
 uint8u8Version;
} tsCLD_ZllUtility_EndpointInformationCommandPayload;
```

where:

- u64IEEEAddr is the IEEE (MAC) address of the local node.
- u16NwkAddr is the network (short) address of the local node.
- u8Endpoint is the number of the local endpoint (1-240).
- u16ProfileID is the identifier of the ZigBee application profile supported on the local endpoint.

- u16DeviceID is identifier of the ZigBee device on the local endpoint.
- u8Version specifies the version number of the ZigBee device on the local endpoint.

Parent topic:*Touchlink Commissioning Cluster*

Enumerations

Touchlink event enumerations The event types generated by the Touchlink part of the Touchlink Commissioning cluster are enumerated in the teCLD_ZllCommission_Command structure below:

```
typedef enum PACK
{
  E_CLD_COMMISSION_CMD_SCAN_REQ  0x00,
  E_CLD_COMMISSION_CMD_SCAN_RSP,
  E_CLD_COMMISSION_CMD_DEVICE_INFO_REQ,
  E_CLD_COMMISSION_CMD_DEVICE_INFO_RSP,
  E_CLD_COMMISSION_CMD_IDENTIFY_REQ  0x06,
  E_CLD_COMMISSION_CMD_FACTORY_RESET_REQ,
  E_CLD_COMMISSION_CMD_NETWORK_START_REQ  0x10,
  E_CLD_COMMISSION_CMD_NETWORK_START_RSP,
  E_CLD_COMMISSION_CMD_NETWORK_JOIN_ROUTER_REQ,
  E_CLD_COMMISSION_CMD_NETWORK_JOIN_ROUTER_RSP,
  E_CLD_COMMISSION_CMD_NETWORK_JOIN_END_DEVICE_REQ,
  E_CLD_COMMISSION_CMD_NETWORK_JOIN_END_DEVICE_RSP,
  E_CLD_COMMISSION_CMD_NETWORK_UPDATE_REQ,
} teCLD_ZllCommission_Command;
```

Parent topic: Enumerations

Commissioning utility event enumerations The event types generated by the Commissioning Utility part of the Touchlink Commissioning cluster are enumerated in the teCLD_ZllUtility_Command structure below:

```
 typedef enum PACK
{
  E_CLD_UTILITY_CMD_ENDPOINT_INFO = 0x40,
  E_CLD_UTILITY_CMD_GET_GROUP_ID_REQ_RSP,
  E_CLD_UTILITY_CMD_GET_ENDPOINT_LIST_REQ_RSP,
} teCLD_ZllUtility_Command;
```

Parent topic: Enumerations

Parent topic:*Touchlink Commissioning Cluster*

Compile-time options This section describes the compile-time options that may be enabled in the **zcl_options.h** file of an application that uses the Touchlink Commissioning cluster.

The Touchlink Commissioning cluster is enabled as follows:

- **Touchlink -** To enable the cluster, define CLD_ZLL_COMMISSION, then:
  - to enable the cluster as a server, define ZLL_COMMISSION_SERVER
  - to enable the cluster as a client, define ZLL_COMMISSION_CLIENT

- **Commissioning Utility -** To enable the cluster, define CLD_ZLL_UTILITY, then:
  - to enable the cluster as a server, define ZLL_UTILITY_SERVER
  - to enable the cluster as a client, define ZLL_UTILITY_CLIENT

Parent topic:*Touchlink Commissioning Cluster*

Part XI: Appliances Clusters This part comprises four chapters:

- *Chapter 45* details the **Appliance Control** cluster
- *Chapter 46* details the **Appliance Identification** cluster
- *Chapter 47* details the **Appliance Events and Alerts** cluster
- *Chapter 48* details the **Appliance Statistics** cluster

Appliance Control Cluster This chapter outlines the Appliance Control cluster which provides an interface for remotely controlling appliances in the home.

The Appliance Control cluster has a Cluster ID of 0x001B.

Overview The Appliance Control cluster provides an interface for the remote control and programming of home appliances (e.g. a washing machine) by sending basic operational commands such as start, pause, stop.

The cluster is enabled by defining CLD_APPLIANCE_CONTROL in the **zcl_options.h** file. Further compile-time options for the Appliance Control cluster are detailed in Section 45.10.

All attributes of the Appliance Control cluster are in the 'Appliance Functions' attribute set.

Parent topic:*Appliance Control Cluster*

Cluster structure and attributes The structure definition for the Appliance Control cluster (server) is:

```
typedef struct
{
#ifdef APPLIANCE_CONTROL_SERVER
    zuint16                 u16StartTime;
    zuint16                 u16FinishTime;
#ifdef CLD_APPLIANCE_CONTROL_REMAINING_TIME
    zuint16                 u16RemainingTime;
#endif
#ifdef CLD_APPLIANCE_CONTROL_ATTRIBUTE_REPORTING_STATUS
    zenum8                  u8AttributeReportingStatus;
#endif
#endif
    zuint16                 u16ClusterRevision;
} tsCLD_ApplianceControl;
```

where:

- u16StartTime is a bitmap representing the start-time of a 'running' cycle of the appliance, as follows:

Bits	Description
0-5	Minutes part of the start-time, in the range 0 to 59

(may be absolute or relative time - see below)

| |6-7|Type of time encoding:

- 0x0: Relative time - start-time is a delay from the time that the attribute was set
- 0x1: Absolute time - start-time is an actual time of the 24-hour clock
- 0x2-0x3: Reserved

The defaults are absolute time for ovens and relative time for other appliances.

| |8-15|Hours part of the start-time:

- in the range 0 to 255, if relative time selected
- in the range 0 to 23, if absolute time selected

|

- u16FinishTime is a bitmap representing the stop-time of a 'running' cycle of the appliance, as follows:

Bits	Description
0-5	Minutes part of the stop-time, in the range 0 to 59

(may be absolute or relative time - see below)

| |6-7|Type of time encoding:

- 0x0: Relative time - stop-time is a delay from the time that the attribute was set
- 0x1: Absolute time - stop-time is an actual time of the 24-hour clock
- 0x2-0x3: Reserved

The defaults are absolute time for ovens and relative time for other appliances.

| |8-15|Hours part of the stop-time:

- in the range 0 to 255, if relative time selected
- in the range 0 to 23, if absolute time selected

|

- u16RemainingTime is an optional attribute indicating the time, in minutes, remaining in the current 'running' cycle of the appliance (time until the end of the cycle) - this attribute is constantly updated during the running cycle and is zero when the appliance is not running
- u8AttributeReportingStatus is an optional attribute that should be enabled when attribute reporting is used for the cluster (see Section 2.3.5). The value of this attribute indicates whether there are attribute reports still pending (0x00) or the attribute reports are complete (0x01) - all other values are reserved. This attribute is also described in Section 2.4.
- u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specification on which this cluster instance is based. The cluster specification in the ZCL r6 corresponds to a cluster revision of 1. The value is incremented by one for each subsequent revision of the cluster specification. This attribute is also described in Section 2.4.

Parent topic:*Appliance Control Cluster*

Attributes for default reporting The following attributes of the Appliance Control cluster can be selected for default reporting:

```
u16StartTime
u16FinishTime
```

- u16RemainingTime

Attribute reporting (including default reporting) is described in *Appendix B.* Enabling reports for these attributes is described in Appendix B.3.6.

Parent topic:*Appliance Control Cluster*

Sending commands The Appliance Control cluster server resides on the appliance to be controlled (e.g. a washing machine) and the cluster client resides on the controlling device (normally a remote control unit).

The commands from the client to the server can be of two types:

- 'Execution' commands, requesting appliance operations
- 'Status' commands, requesting appliance status information

In addition, status notification messages can be sent unsolicited from the server to the client.

Sending the above messages is described in the sub-sections below.

Execution Commands from Client to Server An 'execution' command can be sent from the client to request that an operation is performed on the appliance (server) - the request is sent in an 'Execution of Command' message. The application on the client can send this message by calling the function **eCLD_ACExecutionOfCommandSend()**.

The possible operations depend on the target appliance but the following operations are available to be specified in the message payload (described in Section 45.9.2):

- Start appliance cycle
- Stop appliance cycle
- Pause appliance cycle
- Start superfreezing cycle
- Stop superfreezing cycle
- Start supercooling cycle
- Stop supercooling cycle
- Disable gas
- Enable gas

In the start and stop commands, the start-time and end-time can be specified. The commands are fully detailed in the British Standards document BS EN 50523.

The application on the server (appliance) will be notified of the received command by an E_CLD_APPLIANCE_CONTROL_CMD_EXECUTION_OF_COMMAND event (Appliance Control events are described in Section 45.5). The required command is specified in the payload of the message, which is contained in the above event. The application must then perform the requested command (if possible).

Parent topic: Sending commands

Status Commands from Client to Server The application on the cluster client can request the current status of the appliance by sending a 'Signal State' message to the cluster server on the appliance. This message can be sent by calling the function **eCLD_ACSignalStateSend()**. This function returns immediately and the requested status information is later returned in an E_CLD_APPLIANCE_CONTROL_CMD_SIGNAL_STATE_RESPONSE event, which is generated when a response arrives from the server (Appliance Control events are described in Section 45.5).

Note: The cluster server handles the 'Signal State' message automatically and returns the requested status information in a 'Signal State Response' message to the client.

The appliance status information from the message payload is contained in the above event - for details of this payload and the status information, refer to Section 45.9.3.

Parent topic: Sending commands

Status Notifications from Server to Client The cluster server on the appliance can send unsolicited status notifications to the client in 'Signal State Notification' messages. A message of this kind can be sent by the application on the server by calling either of the following functions:

- **eCLD_ACSignalStateNotificationSend()**
- **eCLD_ACSignalStateResponseORSignalStateNotificationSend()**

Note: The latter function is also used internally by the cluster server to send a 'Signal State Response' message - see Section 45.4.2.

The appliance status information from the 'Signal State Notification' message is reported to the application on the cluster client through the event E_CLD_APPLIANCE_CONTROL_CMD_SIGNAL_STATE_NOTIFICATION, which is generated when the notification arrives from the server (Appliance Control events are described in Section 45.5). The appliance status information from the message payload is contained in the above event - for details of this payload and the status information, refer to Section 45.9.3.

Parent topic: Sending commands

Parent topic:*Appliance Control Cluster*

Appliance control events The Appliance Control cluster has its own events that are handled through the callback mechanism described in *Chapter 3*. The cluster contains its own event handler. If a device uses this cluster then application-specific Appliance Control event handling must be included in the user-defined callback function for the associated endpoint, where this callback function is registered through the relevant endpoint registration function. This callback function will then be invoked when an Appliance Control event occurs and needs the attention of the application.

For an Appliance Control event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsCLD_ApplianceControlCallBackMessage structure:

```
typedef struct
{
    uint8   u8CommandId;
    bool   *pbApplianceStatusTwoPresent;
    union
    {
        tsCLD_AC_ExecutionOfCommandPayload *psExecutionOfCommandPayload;
        tsCLD_AC_SignalStateResponseORSignalStateNotificationPayload
                                    *psSignalStateResponseAndNotificationPayload;
    } uMessage;
} tsCLD_ApplianceControlCallBackMessage;
```

When an Appliance Control event occurs, one of four command types could have been received. The relevant command type is specified through the u8CommandId field of the tsSM_CallBackMessage structure. The possible command types are detailed the tables below for events generated on a server and a client.

u8CommandId Enumeration	Description
E_CLD_APPLIANCE_CONTROL_	

CMD_EXECUTION_OF_COMMAND

|An 'Execution of Command' message has been received by the server (appliance), requesting an opera-tion on the appliance| |E_CLD_APPLIANCE_CONTROL_

CMD_SIGNAL_STATE

|A 'Signal State' message has been received by the server (appliance), requesting the status of the appli-ance|

u8CommandId Enumeration	Description
E_CLD_APPLIANCE_CONTROL_CM-D_SIGNAL_STATE_RESPONSE	A response to a 'Signal State' message has been received by the client, containing the requested appli-ance status
E_CLD_APPLIANCE_CONTROL_CM-D_SIGNAL_STATE_NOTIFICATION	A 'Signal State' notification message has been received by the client, containing unsolicited status information

Parent topic:*Appliance Control Cluster*

Functions The following Appliance Control cluster functions are provided:

1. eCLD_ApplianceControlCreateApplianceControl
2. eCLD_ACExecutionOfCommandSend
3. eCLD_ACSignalStateSend
4. eCLD_ACSignalStateResponseORSignalStateNotificationSend
5. eCLD_ACSignalStateNotificationSend
6. eCLD_ACChangeAttributeTime

eCLD_ApplianceControlCreateApplianceControl

```
teZCL_Status eCLD_ApplianceControlCreateApplianceControl(
    tsZCL_ClusterInstance *psClusterInstance,
    bool_t bIsServer,
    tsZCL_ClusterDefinition *psClusterDefinition,
    void *pvEndPointSharedStructPtr,
    uint8 *pu8AttributeControlBits,
    tsCLD_ApplianceControlCustomDataStructure
    *psCustomDataStructure);
```

Description This function creates an instance of the Appliance Control cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device).

This function will create an Appliance Control cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions. For more details of creating cluster instances on custom endpoints, refer to *Appendix D.*

Note: This function must not be called for an endpoint on which a standard ZigBee device is used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function from those described in the *ZigBee Devices User Guide**(JNUG3131)*.

When used, this function must be the first Appliance Control cluster function called in the application, and must be called after the stack has been started and after the ZCL has been initialized.

The function requires an array to be declared for internal use, which contains one element (of type **uint8**) for each attribute of the cluster. The array length is automatically adjusted by the compiler using the following declaration:

```
uint8 au8ApplianceControlAttributeControlBits
[(sizeof(asCLD_ApplianceControlClusterAttributeDefinitions) / sizeof(tsZCL_AttributeDefinition))];
```

Parameters

- *psClusterInstance* Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initialising individual structure fields.
- *bIsServer* Type of cluster instance (server or client) to be created:
  - TRUE - server
  - FALSE - client
- *psClusterDefinition* Pointer to structure indicating the type of cluster to be created (see Section 6.1.2). In this case, this structure must contain the details of the Appliance Control cluster. This parameter can refer to a pre-filled structure called sCLD_ApplianceControl which is provided in the **ApplianceControl.h** file.
- *pvEndPointSharedStructPtr* Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_ApplianceControl which defines the attributes of Appliance Control cluster. The function initializes the attributes with default values.
- *pu8AttributeControlBits* Pointer to an array of **uint8** values, with one element for each attribute in the cluster (see above). For a cluster client, set this pointer to NULL.
- *psCustomDataStructure* Pointer to a structure containing the storage for internal functions of the cluster (see Section 45.9.4)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_ACExecutionOfCommandSend

```
teZCL_Status eCLD_ACExecutionOfCommandSend(
        uint8 u8SourceEndPointId,
        uint8 u8DestinationEndPointId,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        tsCLD_AC_ExecutionOfCommandPayload *psPayload);
```

Description This function can be used on an Appliance Control cluster client to send an 'Execution of Command' message to a cluster server (appliance), where this message may specify one of the following control commands:

- Start appliance cycle
- Stop appliance cycle
- Pause appliance cycle
- Start superfreezing cycle
- Stop superfreezing cycle
- Start supercooling cycle
- Stop supercooling cycle
- Disable gas
- Enable gas

The required command is specified in the payload of the message (a pointer to this payload must be provided). The commands are fully detailed in the British Standards document BS EN 50523.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the message. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameter

- *u8SourceEndPointId* Number of the local endpoint through which to send the message. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId* Number of the endpoint on the remote node to which the message is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress* Pointer to a structure holding the address of the node to which the request is sent
- *pu8TransactionSequenceNumber* Pointer to a location to receive the Transaction Sequence Number (TSN) of the message
- *psPayload* Pointer to a structure containing the payload for the message (see Section 45.9.2).

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL

- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_ACSignalStateSend

```
teZCL_Status eCLD_ACSignalStateSend(
        uint8 u8SourceEndPointId,
        uint8 u8DestinationEndPointId,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used on an Appliance Control cluster client to send a 'Signal State' message to a cluster server (appliance), which requests the status of the appliance. The function returns immediately and the requested status information is later returned in the following event, which is generated when a response is received from the server:

E_CLD_APPLIANCE_CONTROL_CMD_SIGNAL_STATE_RESPONSE

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the message. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the message. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the message is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the message is sent
- *psDestinationAddress*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the message

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_ACSignalStateResponseORSignalStateNotificationSend

```
teZCL_Status eCLD_ACSignalStateResponseORSignalStateNotificationSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
```

(continues on next page)

(continued from previous page)

```
    teCLD_ApplianceControl_ServerCommandId eCommandId,
    bool bApplianceStatusTwoPresent,
    tsCLD_AC_SignalStateResponseORSignalStateNotificationPayload
*psPayload);
```

Description This function can be used on an Appliance Control cluster server to send a 'Signal State Response' message (in reply to a 'Signal State Request' message) or an unsolicited 'Signal State Notification' message to a cluster client.

The command to be sent must be specified as one of:

- E_CLD_APPLIANCE_CONTROL_CMD_SIGNAL_STATE_RESPONSE
- E_CLD_APPLIANCE_CONTROL_CMD_SIGNAL_STATE_NOTIFICATION

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the message. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which to send the message. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId* Number of the endpoint on the remote node to which the message is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress* Pointer to a structure holding the address of the node to which the message is sent
- *pu8TransactionSequenceNumber* Pointer to a location to receive the Transaction Sequence Number (TSN) of the message
- *eCommandId* Enumeration indicating the command to be sent (see above and Section 45.8.3)
- *bApplianceStatusTwoPresent* Boolean indicating whether additional appliance status data is present in payload:
  - TRUE - Present
  - FALSE - Not present
- *psPayload* Pointer to structure containing payload for message (see above and Section 45.9.3)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_ACSignalStateNotificationSend

```
teZCL_Status eCLD_ACSignalStateNotificationSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    bool bApplianceStatusTwoPresent,
    tsCLD_AC_SignalStateResponseORSignalStateNotificationPayload**
*psPayload);
```

Description This function can be used on an Appliance Control cluster server to send an unsolicited 'Signal State Notification' message to a cluster client. The function is an alternative to **eCLD_ACSignalStateResponseORSignalStateNotificationSend()**.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the message. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the message. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId*: Number of the endpoint on the remote node to which the message is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress*: Pointer to a structure holding the address of the node to which the message is sent
- *psDestinationAddress*: Pointer to a location to receive the Transaction Sequence Number (TSN) of the message
- *bApplianceStatusTwoPresent*: Boolean indicating whether additional appliance status data is present in payload:
  - TRUE - Present
  - FALSE - Not present
- **psPPayload*: Pointer to structure containing payload for message (see above and Section 45.9.3)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_ACChangeAttributeTime

```
teZCL_Status eCLD_ACChangeAttributeTime(
        uint8 u8SourceEndPointId,
        teCLD_ApplianceControl_Cluster_AttrID eAttributeTimeId,
        uint16 u16TimeValue);
```

Description This function can be used on an Appliance Control cluster server (appliance) to update the time attributes of the cluster (start time, finish time, remaining time). This is particularly useful if the host node has its own timer.

The target attribute must be specified using one of:

- E_CLD_APPLIANCE_CONTROL_ATTR_ID_START_TIME
- E_CLD_APPLIANCE_CONTROL_ATTR_ID_FINISH_TIME
- E_CLD_APPLIANCE_CONTROL_ATTR_ID_REMAINING_TIME

Parameters

- *u8SourceEndPointId*: Number of the local endpoint through which to send the message. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *eAttributeTimeId*: Identifier of attribute to be updated (see above and Section 45.9.1)
- *u16TimeValue*: UTC time to set

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

Parent topic:*Appliance Control Cluster*

Return codes The Appliance Control cluster functions use the ZCL return codes, listed in Section7.2.

Parent topic:*Appliance Control Cluster*

Enumerations

'Attribute ID' Enumerations The following structure contains the enumerations used to identify the attributes of the Appliance Control cluster.

```
typedef enum PACK
{
   E_CLD_APPLIANCE_CONTROL_ATTR_ID_START_TIME     = 0x0000,
   E_CLD_APPLIANCE_CONTROL_ATTR_ID_FINISH_TIME,
   E_CLD_APPLIANCE_CONTROL_ATTR_ID_REMAINING_TIME
} teCLD_ApplianceControl_Cluster_AttrID;
```

Parent topic: Enumerations

'Client Command ID' Enumerations The following enumerations are used in commands issued on a cluster client.

```
typedef enum PACK
{
    E_CLD_APPLIANCE_CONTROL_CMD_EXECUTION_OF_COMMAND = 0x00,
    E_CLD_APPLIANCE_CONTROL_CMD_SIGNAL_STATE,
} teCLD_ApplianceControl_ClientCommandId;
```

The above enumerations are described in the table below.

Enumeration	Description
E_CLD_APPLIANCE_CONTROL_CMD_EXECUTION_OF_COMM	'Execution of Command' message
E_CLD_APPLIANCE_CONTROL_CMD_SIGNAL_STATE	'Signal State' message

Parent topic: Enumerations

'Server command ID' enumerations The following enumerations are used in commands issued on a cluster server.

```
typedef enum PACK
{
    E_CLD_APPLIANCE_CONTROL_CMD_SIGNAL_STATE_RESPONSE = 0x00,
    E_CLD_APPLIANCE_CONTROL_CMD_SIGNAL_STATE_NOTIFICATION
} teCLD_ApplianceControl_ServerCommandId;
```

The above enumerations are described in the table below.

Enumeration	Description
E_CLD_APPLIANCE_CONTROL_CMD_SIGNAL_STATE_RESPO	A response to a 'Signal State' request
E_CLD_APPLIANCE_CONTROL_CMD_SIGNAL_STATE_NOTIFI	A 'Signal State' notification

Parent topic: Enumerations

Parent topic:*Appliance Control Cluster*

Structures

tsCLD_ApplianceControlCallBackMessage For an Appliance Control event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsCLD_ApplianceControlCallBackMessage structure:

```
typedef struct
{
    uint8    u8CommandId;
```

(continues on next page)

(continued from previous page)

```
    bool    *pbApplianceStatusTwoPresent;
    union
    {
        tsCLD_AC_ExecutionOfCommandPayload                          *psExecutionOfCommandPayload;
        tsCLD_AC_SignalStateResponseORSignalStateNotificationPayload
                                *psSignalStateResponseAndNotificationPayload;
    } uMessage;
} tsCLD_ApplianceControlCallBackMessage;
```

where:

- u8CommandId indicates the type of Appliance Control command that has been received, one of:
  - E_CLD_APPLIANCE_CONTROL_CMD_EXECUTION_OF_COMMAND
  - E_CLD_APPLIANCE_CONTROL_CMD_SIGNAL_STATE
  - E_CLD_APPLIANCE_CONTROL_CMD_SIGNAL_STATE_RESPONSE
  - E_CLD_APPLIANCE_CONTROL_CMD_SIGNAL_STATE_NOTIFICATION
- pbApplianceStatusTwoPresent is a pointer to a boolean indicating whether a second set of non-standard or proprietary status data is available:
  - TRUE - additional status data available
  - FALSE - additional status data unavailable
- uMessage is a union containing the command payload as one of (depending on the value of u8CommandId):
- psExecutionOfCommandPayload is a pointer to the payload of an 'Execution of Command' message (see Section 45.9.2)
- psSignalStateResponseAndNotificationPayload is a pointer to the payload of a 'Signal State' response or notification message (see Section 45.9.3)

Parent topic: Structures

tsCLD_AC_ExecutionOfCommandPayload This structure contains the payload for an "Execution of Command" message.

```
typedef struct
{
        zenum8                  eExecutionCommandId;
} stsCLD_AC_ExecutionOfCommandPayload;
```

where eExecutionCommandId is a value representing the command to be executed - the commands are detailed in the British Standards document BS EN 50523.

Parent topic: Structures

tsCLD_AC_SignalStateResponseORSignalStateNotificationPayload This structure contains the payload for a "Signal State" response or notification message.

```
typedef struct
{
        zenum8  eApplianceStatus;
        zuint8                  u8RemoteEnableFlagAndDeviceStatus;
        zuint24                         u24ApplianceStatusTwo;
```

(continues on next page)

(continued from previous page)

```
} tsCLD_AC_SignalStateResponseORSignalStateNotificationPayload;
```

where:

- eApplianceStatus is a value indicating the reported appliance status (the relevant status values depend on the appliance):

Status Value	Description
0x00	Reserved
0x01	Appliance in off state
0x02	Appliance in stand-by
0x03	Appliance already programmed
0x04	Appliance already programmed and ready to start
0x05	Appliance is running
0x06	Appliance is in pause state
0x07	Appliance end programmed tasks
0x08	Appliance is in a failure state
0x09	Appliance programmed tasks have been interrupted
0x0A	Appliance in idle state
0x0B	Appliance rinse hold
0x0C	Appliance in service state
0x0D	Appliance in superfreezing state
0x0E	Appliance in supercooling state
0x0F	Appliance in superheating state
0x10-0x3F	Reserved
0x40-0x7F	Non-standardised
0x80-0xFF	Proprietary

- u8RemoteEnableFlagAndDeviceStatus is a bitmap value indicating the status of the relationship between the appliance and the remote control unit as well as the type of additional status information reported in u24ApplianceStatusTwo:

Bits	Field	Values/Description
0-3	Remote Enable Flags	Status of remote control link:

  - 0x0: Disabled
  - 0x1: Enabled remote and energy control
  - 0x2-0x06: Reserved
  - 0x7: Temporarily locked/disabled
  - 0x8-0xE: Reserved
  - 0xF: Enabled remote control

| |4-7|Device Status 2|Type of information in u24ApplianceStatusTwo:

  - 0x0: Proprietary
  - 0x1: Proprietary
  - 0x2: IRIS symptom code
  - 0x3-0xF: Reserved

|

- u24ApplianceStatusTwo is a value indicating non-standard or proprietary status information about the appliance. The type of status information represented by this value is indicated

in the 'Device Status 2' field of u8RemoteEnableFlagAndDeviceStatus. In the case of an IRIS symptom code, the three bytes of this value represent a 3-digit code.

Parent topic: Structures

tsCLD_ApplianceControlCustomDataStructure The Appliance Control cluster requires extra storage space to be allocated to be used by internal functions. The structure definition for this storage is shown below:

```
typedef struct
{
    tsZCL_ReceiveEventAddress                sReceiveEventAddress;
    tsZCL_CallBackEvent                      sCustomCallBackEvent;
    tsCLD_ApplianceControlCallBackMessage    sCallBackMessage;
} tsCLD_ApplianceControlCustomDataStructure;
```

The fields are for internal use and no knowledge of them is required.

Parent topic: Structures

Parent topic:*Appliance Control Cluster*

Compile-time options This section describes the compile-time options that may be enabled in the **zcl_options.h** file of an application that uses the Appliance Control cluster.

To enable the Appliance Control cluster in the code to be built, it is necessary to add the following line to the file:

```
#define CLD_APPLIANCE_CONTROL
```

In addition, to enable the cluster as a client or server, it is also necessary to add one of the following lines to the same file:

```
#define APPLIANCE_CONTROL_SERVER
#define APPLIANCE_CONTROL_CLIENT
```

The Appliance Control cluster contains macros that may be optionally specified at compile-time by adding one or more of the following lines to the **zcl_options.h** file.

Optional attributes Add this line to enable the optional Time Remaining attribute:

```
#define CLD_APPLIANCE_CONTROL_REMAINING_TIME
```

Global Attributes Add this line to enable the optional Attribute Reporting Status attribute:

```
#define CLD_LEVELCONTROL_ATTR_ID_ATTRIBUTE_REPORTING_STATUS
```

Add this line to define the value (n) of the Cluster Revision attribute:

```
#define CLD_LEVELCONTROL_CLUSTER_REVISION <n>
```

The default value is 1, which corresponds to the revision of the cluster in the ZCL r6 specification (see Section 2.4).

Parent topic:*Appliance Control Cluster*

Appliance Identification Cluster This chapter outlines the Appliance Identification cluster, which provides an interface for obtaining and setting basic appliance information.

The Appliance Identification cluster has a Cluster ID of 0x0B00.

- **Overview**
- **Cluster structure and attributes**
- **Functions**
- **Return codes**
- **Enumerations**
- **Compile-time options**

Appliance Events and Alerts Cluster This chapter outlines the Appliance Events and Alerts cluster, which provides an interface for the notification of significant events and alert situations.

The Appliance Events and Alerts cluster has a Cluster ID of 0x0B02.

Overview The Appliance Events and Alerts cluster provides an interface for sending notifications of appliance events (for example, target temperature reached) and alerts (for example, alarms).

The cluster is enabled by defining CLD_APPLIANCE_EVENTS_AND_ALERTS in the **zcl_options.h** file. Further compile-time options for the Appliance Events and Alerts cluster are detailed in Section 47.9.

Events are notified in terms of header and event identifier fields (an event may occur when the appliance reaches a certain state, such as the end of its operational cycle).

Alerts are notified in terms of the following fields:

- Alert identification value
- Alert category, one of: Warning, Danger, Failure
- Presence/recovery flag (indicating alert has been either detected or recovered)

Parent topic:*Appliance Events and Alerts Cluster*

Cluster structure and attribute The structure definition for the Appliance Events and Alerts cluster (server) is.

```
typedef struct
{
 zuint16    u16ClusterRevision;
} tsCLD_ApplianceEventsAndAlerts;
```

where u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specification on which this cluster instance is based. The cluster specification in the ZCL r6 corresponds to a cluster revision of 1. The value is incremented by one for each subsequent revision of the cluster specification. This attribute is also described in Section 2.4.

Parent topic:*Appliance Events and Alerts Cluster*

Sending Messages The Appliance Events and Alerts cluster server resides on the appliance (for example, a washing machine) and the cluster client resides on a controlling device (normally a remote control unit).

Messages can be sent between the client and the server in the following ways:

- Alerts that are active on the appliance can be requested by the client by sending a 'Get Alerts' message to the server (which replies with a 'Get Alerts Response' message).
- Alerts that are active on the appliance can be sent unsolicited from the server to the client in an 'Alerts Notification' message.
- The server can notify the client of an appliance event by sending an unsolicited 'Event Notification' message to the client

Sending the above messages is described in the sub-sections below.

'Get Alerts' Messages from Client to Server The application on the cluster client can request the alerts that are currently active on the appliance by sending a 'Get Alerts' message to the server - this message is sent by calling the function **eCLD_AEAAGetAlertsSend()**. This function returns immediately and the requested alerts are later returned in an E_CLD_APPLIANCE_EVENTS_AND_ALERTS_CMD_GET_ALERTS event, which is generated when a response arrives from the server (Appliance Events and Alerts events are described in Section 47.4).

Note: The cluster server handles the 'Get Alerts' message automatically and returns the requested alerts in a 'Get Alerts Response' message to the client.

The appliance alerts from the message payload are contained in the above event - for details of this payload and the alert information, refer to Section 47.8.2. Up to 15 alerts can be reported in a single response.

Parent topic: Sending Messages

'Alerts Notification' Messages from Server to Client The cluster server on the appliance can send unsolicited alert notifications to the client in 'Alerts Notification' messages. The application on the server can send a message of this kind by calling either of the following functions:

- **eCLD_AEAAAlertsNotificationSend()**
- **eCLD_AEAAGetAlertsResponseORAlertsNotificationSend()**

Note: The latter function is also used internally by the cluster server to send a 'Get Alerts Response' message - see Section 47.3.1.

The appliance status information from the 'Alerts Notification' message is reported to the application on the cluster client through the event E_CLD_APPLIANCE_EVENTS_AND_ALERTS_CMD_ALERTS_NOTIFICATION, which is generated when the notification arrives from the server (Appliance Events and Alerts events are described in Section 47.4). The appliance alerts from the message payload are contained in the above event - for details of this payload and the alert information, refer to Section 47.8.2. Up to 15 alerts can be reported in a single notification.

Parent topic: Sending Messages

'Event Notification' Messages from Server to Client The cluster server on the appliance can send unsolicited event notifications to the client in 'Event Notification' messages, where each message reports a single appliance event (for example, oven has reached its target temperature). A message of this kind can be sent by the application on the server by calling the function **eCLD_AEAAEventNotificationSend()**.

The appliance event information from the 'Event Notification' message is reported to the application on the cluster client through the event E_CLD_APPLIANCE_EVENTS_AND_ALERTS_CMD_ALERTS_NOTIFICATION, which is generated when the notification arrives from the server (Appliance Events and Alerts events are described in Section 47.4). The appliance event from the message payload is contained in the above client event - for details of this payload and the embedded appliance event information, refer to Section 47.8.3.

Parent topic: Sending Messages

Parent topic:*Appliance Events and Alerts Cluster*

Appliance Events and Alerts Events The Appliance Events and Alerts cluster has its own events that are handled through the callback mechanism described in *Chapter 3*. The cluster contains its own event handler. If a device uses this cluster then application-specific Appliance Events and Alerts event handling must be included in the user-defined callback function for the associated endpoint, where this callback function is registered through the relevant endpoint registration function. This callback function is then invoked when an Appliance Events and Alerts event occurs and needs the attention of the application.

For an Appliance Events and Alerts event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsCLD_ApplianceEventsAndAlertsCallBackMessage structure:

```
typedef struct
{
  uint8  u8CommandId
  union
  {
  tsCLD_AEAA_GetAlertsResponseORAlertsNotificationPayload
  *psGetAlertsResponseORAlertsNotificationPayload;
  tsCLD_AEAA_EventNotificationPayload
  *psEventNotificationPayload;
  }uMessage;
} tsCLD_ApplianceEventsAndAlertsCallBackMessage;
```

When an Appliance Events and Alerts event occurs, one of four command types could have been received. The relevant command type is specified through the u8CommandId field of the tsSM_CallBackMessage structure. The possible command types are detailed the tables below for events generated on a server and a client.

u8CommandId Enumeration	Description
E_CLD_APPLIANCE_EVENTS_AND_ALERTS_Cl	A 'Get Alerts' request has been received by the server (appliance)

u8CommandId Enumeration	Description
E_CLD_APPLIANCE_EVENTS_AND_AL	A response to a 'Get Alerts' request has been received by the client, containing the requested alerts (up to 15)
E_CLD_APPLIANCE_EVENTS_AND_AL	An 'Alerts Notification' message has been received by the client, containing unsolicited alerts (up to 15)
E_CLD_APPLIANCE_EVENTS_AND_AL	An 'Event Notification' message has been received by the client

Parent topic:*Appliance Events and Alerts Cluster*

Functions The following Appliance Events and Alerts cluster functions are provided:

1. eCLD_ApplianceEventsAndAlertsCreateApplianceEventsAndAlerts
2. eCLD_AEAAGetAlertsSend
3. eCLD_AEAAGetAlertsResponseORAlertsNotificationSend
4. eCLD_AEAAAlertsNotificationSend
5. eCLD_AEAAEventNotificationSend

eCLD_ApplianceEventsAndAlertsCreateApplianceEventsAndAlerts

```
teZCL_Status eCLD_ApplianceEventsAndAlertsCreateApplianceEventsAndAlerts(
    tsZCL_ClusterInstance *psClusterInstance,
    bool_t bIsServer,
    tsZCL_ClusterDefinition *psClusterDefinition,
    oid *pvEndPointSharedStructPtr,
    uint8 *pu8AttributeControlBits,
    tsCLD_ApplianceEventsAndAlertsCustomDataStructure
*psCustomDataStructure);
```

Description This function creates an instance of the Appliance Events and Alerts cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function creates an Appliance Events and Alerts cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions. For more details of creating cluster instances on custom endpoints, refer to *Appendix D.*

Note: This function must not be called for an endpoint on which a standard ZigBee device is used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function from those described in the *ZigBee Devices User Guide**(JNUG3131)*.

When used, this function must be the first Appliance Events and Alerts cluster function called in the application, and must be called after the stack has been started and after the ZCL has been initialized.

The function requires an array to be declared for internal use, which contains one element (of type **uint8**) for each attribute of the cluster. The array length is automatically adjusted by the compiler using the following declaration:

```
uint8 au8ApplianceEventsAndAlertsAttributeControlBits
    [(sizeof(asCLD_ApplianceEventsAndAlertsClusterAttributeDefinitions)
    / sizeof(tsZCL_AttributeDefinition))];
```

Parameters

Returns **Parent topic:**Functions

eCLD_AEAAGetAlertsSend

```
teZCL_Status eCLD_AEAAGetAlertsSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used on an Appliance Events and Alerts cluster client to send a 'Get Alerts' message to a cluster server (appliance).

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the message. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameter

Returns **Parent topic:**Functions

eCLD_AEAAGetAlertsResponseORAlertsNotificationSend

```
teZCL_Status eCLD_AEAAGetAlertsResponseORAlertsNotificationSend(
uint8 u8SourceEndPointId,
uint8 u8DestinationEndPointId,
tsZCL_Address *psDestinationAddress,
uint8 *pu8TransactionSequenceNumber,
teCLD_ApplianceEventsAndAlerts_CommandId eCommandId,
tsCLD_AEAA_GetAlertsResponseORAlertsNotificationPayload
*psPayload);
```

Description This function can be used on an Appliance Events and Alerts cluster server to send a 'Get Alerts Response' message (in reply to a 'Get Alerts' message) or an unsolicited 'Alerts Notification' message to a cluster client.

The command to be sent must be specified as one of:

- E_CLD_APPLIANCE_EVENTS_AND_ALERTS_CMD_GET_ALERTS
- E_CLD_APPLIANCE_EVENTS_AND_ALERTS_CMD_ALERTS_NOTIFICATION

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the message. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

Returns **Parent topic:**Functions

eCLD_AEAAAlertsNotificationSend

```
teZCL_Status eCLD_AEAAAlertsNotificationSend(
uint8 u8SourceEndPointId,
uint8 u8DestinationEndPointId,
tsZCL_Address *psDestinationAddress,
uint8 *pu8TransactionSequenceNumber,
tsCLD_AEAA_GetAlertsResponseORAlertsNotificationPayload
*psPayload);
```

Description This function can be used on an Appliance Events and Alerts cluster server to send an unsolicited 'Alerts Notification' message to a cluster client. The function is an alternative to **eCLD_AEAAGetAlertsResponseORAlertsNotificationSend()**.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the message. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

Returns **Parent topic:**Functions

eCLD_AEAAEventNotificationSend

```
teZCL_Status eCLD_AEAAEventNotificationSend(
    uint8 u8SourceEndPointId,
    uint8 u8DestinationEndPointId,
    tsZCL_Address *psDestinationAddress,
    uint8 *pu8TransactionSequenceNumber,
    tsCLD_AEAA_EventNotificationPayload *psPayload);
```

Description This function can be used on an Appliance Events and Alerts cluster server (appliance) to send an 'Event Notification' message to a cluster client, to indicate that an incident has occurred.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the message. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

Returns **Parent topic:**Functions

Parent topic:*Appliance Events and Alerts Cluster*

Return codes The Appliance Events and Alerts cluster functions use the ZCL return codes, listed in Section 7.2.

Parent topic:*Appliance Events and Alerts Cluster*

Enumerations

'Command ID' Enumerations The following enumerations are used in commands received on a cluster server or client.

```
typedef enum PACK
{
  E_CLD_APPLIANCE_EVENTS_AND_ALERTS_CMD_GET_ALERTS = 0x00,
  E_CLD_APPLIANCE_EVENTS_AND_ALERTS_CMD_ALERTS_NOTIFICATION,
  E_CLD_APPLIANCE_EVENTS_AND_ALERTS_CMD_EVENT_NOTIFICATION
} teCLD_ApplianceEventsAndAlerts_CommandId;
```

The above enumerations are described in the table below.

Enumeration	Description
E_CLD_APPLIANCE_EVENTS_AND_ALERTS_CMD_GET	'Get Alerts' request (on server) or response (on client)
E_CLD_APPLIANCE_EVENTS_AND_ALERTS_CMD_ALE	Alerts notification (on client)
E_CLD_APPLIANCE_EVENTS_AND_ALERTS_CMD_EVE	Events notification (on server)

Parent topic: Enumerations

Parent topic:*Appliance Events and Alerts Cluster*

Structures

tsCLD_ApplianceEventsAndAlertsCallBackMessage For an Appliance Events and Alerts event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsCLD_ApplianceEventsAndAlertsCallBackMessage structure:

```
typedef struct
{
 uint8    u8CommandId
 union
 {
 tsCLD_AEAA_GetAlertsResponseORAlertsNotificationPayload
       *psGetAlertsResponseORAlertsNotificationPayload;
 tsCLD_AEAA_EventNotificationPayload
       *psEventNotificationPayload;
 } uMessage;
} tsCLD_ApplianceEventsAndAlertsCallBackMessage;
```

where:

- u``8CommandId indicates the type of Appliance Events and Alerts command that has been received, one of:
  - E_CLD_APPLIANCE_EVENTS_AND_ALERTS_CMD_GET_ALERTS
  - E_CLD_APPLIANCE_EVENTS_AND_ALERTS_CMD_ALERTS_NOTIFICATION
  - E_CLD_APPLIANCE_EVENTS_AND_ALERTS_CMD_EVENT_NOTIFICATION
- u``Message is a union containing the command payload as one of (depending on the value of u8CommandId):

– psGetAlertsResponseORAlertsNotificationPayload is a pointer to the payload of an “Get Alerts” response message or an alerts notification message (see Section 47.8.2)

– psEventNotificationPayload is a pointer to the payload of an events notification message (see Section 47.8.3)

Parent topic: Structures

tsCLD_AEAA_GetAlertsResponseORAlertsNotificationPayload This structure contains the payload for a ‘Get Alerts Response’ message or an ‘Alerts Notification’ message.

```
typedef struct
{
  zuint8  u8AlertsCount;
  zuint24 au24AlertStructure[
          CLD_APPLIANCE_EVENTS_AND_ALERTS_MAXIMUM_NUM_OF_ALERTS];
} tsCLD_AEAA_GetAlertsResponseORAlertsNotificationPayload;
```

where:

- u8AlertsCount is an 8-bit bitmap containing the following alerts information:

Bits	Description
0-3	Number of reported alerts
4-7	Type of alert:

- 0x0: Unstructured
- 0x1-0xF: Reserved

|

- au24AlertStructure[``] is an array of 24-bit bitmaps, with one bitmap for each reported alert, containing the following information:

Bits	Description
0-7	Alert ID:

- 0x0: Reserved
- 0x01-0x3F: Standardized
- 0x40-0x7F: Non-standardized
- 0x80-0xFF: Proprietary

| |8-11|Category:

- 0x0: Reserved
- 0x1: Warning
- 0x2: Danger
- 0x3: Failure
- 0x4–0xF: Reserved

| |12-13|Presence or recovery:

- 0x0: Presence (alert detected)
- 0x1: Recovery (alert recovered)
- 0x2–0x3: Reserved

| |14-15|Reserved (set to 0x0)| |16-23|Non-standardized or proprietary|

Parent topic: Structures

tsCLD_AEAA_EventNotificationPayload This structure contains the payload for an 'Event Notification' message.

```
typedef struct
{
  zuint8          u8EventHeader;
  zuint8          u8EventIdentification;
} tsCLD_AEAA_EventNotificationPayload;
```

where:

- u8EventHeader is reserved and set to 0
- u8EventIdentification is the identifier of the event being notified:
  - 0x01: End of operational cycle reached
  - 0x02: Reserved
  - 0x03: Reserved
  - 0x04: Target temperature reached
  - 0x05: End of cooking process reached
  - 0x06: Switching off
  - 0xF7: Wrong data
    - (Values 0x00 to 0x3F are standardised, 0x40 to 0x7F are non-standardised, and 0x80 to 0xFF except 0xF7 are proprietary)

Parent topic: Structures

tsCLD_ApplianceEventsAndAlertsCustomDataStructure The Appliance Events and Alerts cluster requires extra storage space to be allocated to be used by internal functions. The structure definition for this storage is shown below:

```
typedef struct
{
   tsZCL_ReceiveEventAddress sReceiveEventAddress;
   tsZCL_CallBackEvent sCustomCallBackEvent;
   tsCLD_ApplianceEventsAndAlertsCallBackMessage sCallBackMessage;
} tsCLD_ApplianceEventsAndAlertsCustomDataStructure;
```

The fields are for internal use and no knowledge of them is required.

Parent topic: Structures

Parent topic:*Appliance Events and Alerts Cluster*

Compile-time options This section describes the compile-time options that may be enabled in the **zcl_options.h** file of an application that uses the Appliance Events and Alerts cluster.

To enable the Appliance Events and Alerts cluster in the code to be built, it is necessary to add the following line to the file:

```
#define CLD_APPLIANCE_EVENTS_AND_ALERTS
```

In addition, to enable the cluster as a client or server, it is also necessary to add one of the following lines to the same file:

```
#define APPLIANCE_EVENTS_AND_ALERTS_SERVER
#define APPLIANCE_EVENTS_AND_ALERTS_CLIENT
```

The Appliance Identification cluster contains macros that may be optionally specified at compile-time by adding one or more of the following lines to the **zcl_options.h** file.

Maximum Number of Alerts Reported The maximum number of alerts that can be reported in a response or notification can be defined (as n) using the following definition in the **zcl_options.h** file:

```
#define CLD_APPLIANCE_EVENTS_AND_ALERTS_MAXIMUM_NUM_OF_ALERTS n
```

The default value is 16, which is the upper limit on this value, and n must therefore not be greater than 16.

Global Attributes Add this line to define the value (n) of the Cluster Revision attribute:

```
#define CLD_APPLIANCE_EVENTS_AND_ALERTS_CLUSTER_REVISION <n>
```

The default value is 1, which corresponds to the revision of the cluster in the ZCL r6 specification (see Section 2.4).

Parent topic:*Appliance Events and Alerts Cluster*

Appliance Statistics Cluster This chapter outlines the Appliance Statistics cluster, which provides an interface for supplying statistical information about an appliance.

The Appliance Statistics cluster has a Cluster ID of 0x0B03.

Overview The Appliance Statistics cluster provides an interface for sending appliance statistics in the form of data logs to a collector node, which may be a gateway.

The cluster is enabled by defining CLD_APPLIANCE_STATISTICS in the **zcl_options.h** file. Further compile-time options for the Appliance Statistics cluster are detailed in Section 48.10.

The cluster client may obtain logs from the server (appliance) in any of the following ways:

- Unsolicited log notifications sent by the server
- Solicited responses obtained by:
  - Client sending ‘Log Queue Request’ to enquire whether logs are available
  - Client sending ‘Log Request’ for each log available
- Semi-solicited responses obtained by:
  - Server sending ‘Statistics Available’ notification to indicate that logs are available
  - Client sending ‘Log Request’ for each log available

Parent topic:*Appliance Statistics Cluster*

Cluster structure and attributes The structure definition for the Appliance Statistics cluster (server) is:

```
typedef struct
{
#ifdef APPLIANCE_STATISTICS_SERVER
    zuint32                 u32LogMaxSize;
    zuint8                  u8LogQueueMaxSize;
#endif
    zuint16                 u16ClusterRevision;
} tsCLD_ApplianceStatistics;
```

where:

- u32LogMaxSize is a mandatory attribute which specifies the maximum size, in bytes, of the payload of a log notification and log response. This value should not be greater than 70 bytes (otherwise the Partition cluster is needed)
- u8LogQueueMaxSize is a mandatory attribute which specifies the maximum number of logs in the queue on the cluster server that are available to be requested by the client
- u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specification on which this cluster instance is based. The cluster specification in the ZCL r6 corresponds to a cluster revision of 1. The value is incremented by one for each subsequent revision of the cluster specification. This attribute is also described in Section 2.4.

Parent topic:*Appliance Statistics Cluster*

Sending messages The Appliance Statistics cluster server resides on the appliance (e.g. a washing machine) and the cluster client resides on a controlling device (normally a remote control unit).

Messages can be sent between the client and the server in the following ways:

- The client can enquire whether any data logs are available on the appliance (server) by sending a 'Log Queue Request' to the server (which will reply with a 'Log Queue Response' message)
- The server can notify the client that data logs are available by sending an unsolicited 'Statistics Available' message to the client
- The client can request a current data log from the appliance (server) by sending a 'Log Request' message to the server (which will reply with a 'Log Response' message)
- The server can send an unsolicited data log to the client in a 'Log Notification' message

Sending the above messages is described in the sub-sections below.

'Log Queue Request' messages from client to server The application on the cluster client can enquire about the availability of data logs on the appliance by sending a 'Log Queue Request' message to the server. This message is sent by calling the function **eCLD_ASCLogQueueRequestSend()**. This function returns immediately and the log availability is later returned in an E_CLD_APPLIANCE_STATISTICS_CMD_LOG_QUEUE_RESPONSE event, which is generated when a response arrives from the server (Appliance Statistics events are described in Section 48.5).

Note: The cluster server handles the 'Log Queue Request' message automatically and returns the requested information in a 'Log Queue Response' message to the client.

The log availability information from the message payload is contained in the above event, and comprises the number of logs currently in the log queue and their log IDs - for details of this payload and the availability information, refer to Section 48.9.4.

Parent topic: Sending messages

'Statistics Available' messages from server to client The cluster server can notify the client when data logs are available by sending an unsolicited 'Statistics Available' message to the client. This message contains the number of logs in the log queue and the log IDs. A message of this kind can be sent by the application on the server by calling either of the following functions:

- **eCLD_ASCStatisticsAvailableSend()**
- **eCLD_ASCLogQueueResponseORStatisticsAvailableSend()**

Note:

1. The latter function is also used internally by the cluster server to send a 'Log Queue Response' message - see Section 48.3.1.
2. Before calling either function, the relevant log(s) should be added to the local log queue as described in Section 48.4.1. This is because the logs need to be in the queue to allow the server to perform further actions on them - for example, to process a 'Log Request'.

The log availability information from the 'Statistics Available' message is reported to the application on the cluster client through the event E_CLD_APPLIANCE_STATISTICS_CMD_STATISTICS_AVAILABLE, which is generated when the message arrives from the server (Appliance Statistics events are described in Section 48.5). The availability information from the message payload is contained in the above event - for details of this payload and the availability information, refer to Section 48.9.4.

Parent topic: Sending messages

'Log Request' messages from client to server The application on the cluster client can request the log with a particular log ID from the appliance by sending a 'Log Request' message to the server. This message is sent by calling the function **eCLD_ASCLogRequestSend()**. This function returns immediately and the requested log information is later returned in an E_CLD_APPLIANCE_STATISTICS_CMD_LOG_QUEUE_RESPONSE event, which is generated when a response arrives from the server (Appliance Statistics events are described in Section 48.5).

Note:

1. This function should normally be called after a 'Log Queue Response' or 'Statistics Available' message has been received by the client, indicating that logs are available on the server.
2. The cluster server handles the 'Log Request' message automatically and returns the requested log information in a 'Log Response' message to the client.

The log information from the message payload is contained in the above event - for details of this payload and the supplied log information, refer to Section 48.9.3.

Parent topic: Sending messages

'Log Notification' messages from server to client The cluster server can supply the client with an individual data log by sending an unsolicited 'Log Notification' message to the client. This message is sent by the application on the server by calling either of the following functions:

- **eCLD_ASCLogNotificationSend()**
- **eCLD_ASCLogNotificationORLogResponseSend()**

Note:

1. The latter function is also used internally by the cluster server to send a 'Log Response' message - see Section 48.3.1.

2. Before calling either function, the relevant log should be in the local log queue (see Section 48.4.1). This is because the log needs to be in the queue to allow the server to perform further actions on it - for example, to process a 'Log Request'.
3. The function **eCLD_ASCAddLog()** used to add a log to the local log queue (see Section 48.4.1) automatically sends a 'Log Notification' message to all bound Appliance Statistics cluster clients.

The log information from the 'Log Notification' message is reported to the application on the cluster client through the event E_CLD_APPLIANCE_STATISTICS_CMD_LOG_NOTIFICATION, which is generated when the message arrives from the server (Appliance Statistics events are described in Section 48.5). The log information from the message payload is contained in the above event - for details of this payload and the supplied log information, refer to Section 48.9.3.

Parent topic: Sending messages

Parent topic:*Appliance Statistics Cluster*

Log Operations on Server Appliance Statistics cluster functions are provided to allow the application on the cluster server (appliance) to perform the following local log operations:

- Add a log to the log queue
- Remove a log from the log queue
- Obtain a list of the logs in the log queue
- Obtain an individual log from the log queue

These operations are described in the sub-sections below.

Adding and Removing Logs A data log can be added to the local log queue (on the cluster server) using the function **eCLD_ASCAddLog()**. The log must be given an identifier and the UTC time at which the log was added must be specified. The length of the log, in bytes, must be less than the value of CLD_APPLIANCE_STATISTICS_ATTR_LOG_MAX_SIZE, which is defined in the **zcl_options.h** files (and must be less than or equal to 70).

The above function also sends a 'Log Notification' message to all bound Appliance Statistics cluster clients.

An existing log can be removed from the local log queue using the function **eCLD_ASCRemoveLog()**. The log is specified using its identifier.

Parent topic: Log Operations on Server

Obtaining Logs A list of the logs that are currently in the local log queue (on the cluster server) can be obtained by calling the function **eCLD_ASCGetLogsAvailable()**. This function provides the number of logs in the queue and a list of the log identifiers.

An individual log from the local log queue can be obtained using the function **eCLD_ASCGetLogEntry()**. The required log is specified by means of its identifier.

Normally, **eCLD_ASCGetLogsAvailable()**is called first to obtain a list of the available logs and then **eCLD_ASCGetLogEntry()**is called for each log.

Parent topic: Log Operations on Server

Parent topic:*Appliance Statistics Cluster*

Appliance statistics events The Appliance Statistics cluster has its own events that are handled through the callback mechanism described in *Chapter 3*. The cluster contains its own event handler. If a device uses this cluster then application-specific Appliance Statistics event handling must be included in the user-defined callback function for the associated endpoint, where this callback function is registered through the relevant endpoint registration function. This callback function will then be invoked when an Appliance Statistics event occurs and needs the attention of the application.

For an Appliance Statistics event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsCLD_ApplianceStatisticsCallBackMessage structure:

```
typedef struct
{
   uint8    u8CommandId;
   union
   {
      tsCLD_ASC_LogNotificationORLogResponsePayload
                              *psLogNotificationORLogResponsePayload;
      tsCLD_ASC_LogQueueResponseORStatisticsAvailablePayload
                              *psLogQueueResponseORStatisticsAvailabePayload;
      tsCLD_ASC_LogRequestPayload   *psLogRequestPayload;
   } uMessage;
} tsCLD_ApplianceStatisticsCallBackMessage;
```

When an Appliance Statistics event occurs, one of four command types could have been received. The relevant command type is specified through the u8CommandId field of the tsSM_CallBackMessage structure. The possible command types are detailed the tables below for events generated on a server and a client.

u8CommandId Enumeration	Description
E_CLD_APPLIANCE_STATISTICS_	

CMD_LOG_REQUEST

|A ‘Log Request’ message has been received by the server (appliance)| |E_CLD_APPLIANCE_STATISTICS_

CMD_LOG_QUEUE_REQUEST

|A ‘Log Queue Request’ message has been received by the server (appliance)|

u8CommandId Enumeration	Description
E_CLD_APPLIANCE_STATISTICS_	

CMD_LOG_NOTIFICATION

|A ‘Log Notification’ message has been received by the client| |E_CLD_APPLIANCE_STATISTICS_

CMD_LOG_RESPONSE

|A ‘Log Response’ message has been received by the client| |E_CLD_APPLIANCE_STATISTICS_

CMD_LOG_QUEUE_RESPONSE

|A ‘Log Queue Response’ message has been received by the client| |E_CLD_APPLIANCE_STATISTICS_

CMD_STATISTICS_AVAILABLE

|A 'Statistics Available' message has been received by the client|

Parent topic:*Appliance Statistics Cluster*

Functions The following Appliance Statistics cluster functions are provided:

1. eCLD_ApplianceStatisticsCreateApplianceStatistics
2. eCLD_ASCAddLog
3. eCLD_ASCRemoveLog
4. eCLD_ASCGetLogsAvailable
5. eCLD_ASCGetLogEntry
6. eCLD_ASCLogQueueRequestSend
7. eCLD_ASCLogRequestSend
8. eCLD_ASCLogQueueResponseORStatisticsAvailableSend
9. eCLD_ASCStatisticsAvailableSend
10. eCLD_ASCLogNotificationORLogResponseSend
11. eCLD_ASCLogNotificationSend

eCLD_ApplianceStatisticsCreateApplianceStatistics

```
teZCL_Status eCLD_ApplianceStatisticsCreateApplianceStatistics(
        tsZCL_ClusterInstance *psClusterInstance,
        bool_t bIsServer,
        tsZCL_ClusterDefinition *psClusterDefinition,
        void *pvEndPointSharedStructPtr,
        uint8 *pu8AttributeControlBits,
        tsCLD_ApplianceStatisticsCustomDataStructure
*psCustomDataStructure);
```

Description This function creates an instance of the Appliance Statistics cluster on an endpoint. The cluster instance is created on the endpoint which is associated with the supplied tsZCL_ClusterInstance structure and can act as a server or a client, as specified.

The function should only be called when setting up a custom endpoint containing one or more selected clusters (rather than the whole set of clusters supported by a standard ZigBee device). This function will create an Appliance Statistics cluster instance on the endpoint, but instances of other clusters may also be created on the same endpoint by calling their corresponding creation functions. For more details of creating cluster instances on custom endpoints, refer to *Appendix D.*

Note: This function must not be called for an endpoint on which a standard ZigBee device is used. In this case, the device and its supported clusters must be registered on the endpoint using the relevant device registration function from those described in the *ZigBee Devices User Guide (JNUG3131).*

Note:

When used, this function must be the first Appliance Statistics cluster function called in the application, and must be called after the stack has been started and after the ZCL has been initialized.

The function requires an array to be declared for internal use, which contains one element (of type **uint8**) for each attribute of the cluster. The array length is automatically adjusted by the compiler using the following declaration:

```
uint8 au8ApplianceStatisticsAttributeControlBits
[(sizeof(asCLD_ApplianceStatisticsClusterAttributeDefinitions) / sizeof(tsZCL_AttributeDefinition))];
```

Parameters

- *psClusterInstance* Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16). This structure is updated by the function by initialising individual structure fields.
- *bIsServer* Type of cluster instance (server or client) to be created:
- TRUE - server
- FALSE - client
- *psClusterDefinition* Pointer to structure indicating the type of cluster to be created (see see Section 6.1.2). In this case, this structure must contain the details of the Appliance Statistics cluster. This parameter can refer to a pre-filled structure called sCLD_ApplianceStatistics which is provided in the **ApplianceStatistics.h** file.
- *pvEndPointSharedStructPtr* Pointer to the shared structure used for attribute storage. This parameter should be the address of the structure of type tsCLD_ApplianceStatistics which defines the attributes of Appliance Statistics cluster. The function initializes the attributes with default values.
- *pu8AttributeControlBits* Pointer to an array of **uint8** values, with one element for each attribute in the cluster (see above). For a cluster client, set this pointer to NULL.
- *psCustomDataStructure* Pointer to a structure containing the storage for internal functions of the cluster (see Section 48.9.6).

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_ASCAddLog

```
teZCL_CommandStatus eCLD_ASCAddLog(
        uint8 u8SourceEndPointId,
        uint32 u32LogId,
        uint8 u8LogLength,
        uint32 u32Time,
        uint8 *pu8LogData);
```

Description This function can be used on an Appliance Statistics cluster server to add a data log to the log queue. The function also sends out a 'Log Notification' message to all bound Appliance Statistics cluster clients.

The length of the data log, in bytes, must be less than the defined value of CLD_APPLIANCE_STATISTICS_ATTR_LOG_MAX_SIZE (which must be less than or equal to 70).

Parameter

- *u8SourceEndPointId* Number of the local endpoint on which the Appliance Statistics cluster server resides
- *u32LogId* Identifier of log
- *u8LogLength* Length of log, in bytes
- *u32Time* UTC time at which log was produced
- *pu8LogData* Pointer to log data

Returns

- E_ZCL_CMDS_SUCCESS
- E_ZCL_CMDS_FAIL
- E_ZCL_CMDS_INVALID_VALUE (log too long)
- E_ZCL_CMDS_INVALID_FIELD (NULL pointer to log data)
- E_ZCL_CMDS_INSUFFICIENT_SPACE

Parent topic: Functions

eCLD_ASCRemoveLog

```
teZCL_CommandStatus eCLD_ASCRemoveLog(
    uint8 u8SourceEndPointId,
    uint32 u32LogId);
```

Description This function can be used on an Appliance Statistics cluster server to remove the specified data log from the log queue.

Parameter

- *u8SourceEndPointId* Number of the local endpoint on which the Appliance Statistics cluster server resides
- *u32LogId* Identifier of log

Returns

- E_ZCL_CMDS_SUCCESS
- E_ZCL_CMDS_FAIL

Parent topic: Functions

eCLD_ASCGetLogsAvailable

```
teZCL_CommandStatus eCLD_ASCGetLogsAvailable(
        uint8 u8SourceEndPointId,
        uint32 *pu32LogId,
        uint8 *pu8LogIdCount);
```

Description This function can be used on an Appliance Statistics cluster server to obtain a list of the data logs in the log queue. The number of available logs and a list of their log IDs will be obtained.

Parameter

- *u8SourceEndPointId* Number of the local endpoint on which the Appliance Statistics cluster server resides
- *pu32LogId* Pointer to an area of memory to receive the list of 32-bit log IDs
- *pu8LogIdCount* Pointer to an area of memory to receive the number of logs in the queue

Returns

- E_ZCL_CMDS_SUCCESS
- E_ZCL_CMDS_FAIL

Parent topic: Functions

eCLD_ASCGetLogEntry

```
teZCL_CommandStatus eCLD_ASCGetLogEntry(
        uint8 u8SourceEndPointId,
        uint32 u32LogId,
        tsCLD_LogTable **ppsLogTable);
```

Description This function can be used on an Appliance Statistics cluster server to obtain the data log with the specified log ID.

Parameter

- *u8SourceEndPointId* Number of the local endpoint on which the Appliance Statistics cluster server resides
- *u32LogId* Log ID of the required data log
- *ppsLogTable* Pointer to a memory location to receive a pointer to the required data log

Returns

- E_ZCL_CMDS_SUCCESS
- E_ZCL_CMDS_FAIL
- E_ZCL_CMDS_NOT_FOUND (specified log not present)

Parent topic: Functions

eCLD_ASCLogQueueRequestSend

```
teZCL_Status eCLD_ASCLogQueueRequestSend(
uint8 u8SourceEndPointId,
uint8 u8DestinationEndPointId,
tsZCL_Address *psDestinationAddress,
uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used on an Appliance Statistics cluster client to send a 'Log Queue Request' message to a cluster server (appliance), in order enquire about the availability of logs on the server.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the message. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which to send the message. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId* Number of the endpoint on the remote node to which the message is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress* Pointer to a structure holding the address of the node to which the message is sent
- *pu8TransactionSequenceNumber* Pointer to a location to receive the Transaction Sequence Number (TSN) of the message

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_ASCLogRequestSend

```
teZCL_Status eCLD_ASCLogRequestSend(
        uint8 u8SourceEndPointId,
        uint8 u8DestinationEndPointId,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        tsCLD_ASC_LogRequestPayload *psPayload);
```

Description This function can be used on an Appliance Statistics cluster client to send a 'Log Request' message to a cluster server (appliance), in order request the data log with a specified log ID.

The function should normally be called after enquiring about log availability using the function **eCLD_ASCLogQueueRequestSend()** or after receiving an unsolicited 'Statistics Available' notification from the server.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the message. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which to send the message. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId* Number of the endpoint on the remote node to which the message is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress* Pointer to a structure holding the address of the node to which the message is sent
- *pu8TransactionSequenceNumber* Pointer to a location to receive the Transaction Sequence Number (TSN) of the message
- *psPayload* Pointer to*a*structure containing the payload for the 'Log Request', including the relevant log ID (see Section 48.9.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_ASCLogQueueResponseORStatisticsAvailableSend

```
teZCL_Status eCLD_ASCLogQueueResponseORStatisticsAvailableSend(
        uint8 u8SourceEndPointId,
        uint8 u8DestinationEndPointId,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        teCLD_ApplianceStatistics_ServerCommandId
eCommandId);
```

Description This function can be used on an Appliance Statistics cluster server to send a 'Log Queue Response' message (in reply to a 'Log Queue Request' message) or an unsolicited 'Statistics Available' message to a cluster client.

The command to be sent must be specified as one of:

- E_CLD_APPLIANCE_STATISTICS_CMD_LOG_QUEUE_RESPONSE
- E_CLD_APPLIANCE_STATISTICS_CMD_STATISTICS_AVAILABLE

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the message. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which to send the message. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values

- *u8DestinationEndPointId* Number of the endpoint on the remote node to which the message is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress* Pointer to a structure holding the address of the node to which the message is sent
- *pu8TransactionSequenceNumber* Pointer to a location to receive the Transaction Sequence Number (TSN) of the message
- *eCommandId* Enumeration indicating the command to be sent (see above and Section 48.8.3)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_ASCStatisticsAvailableSend

```
teZCL_Status eCLD_ASCStatisticsAvailableSend(
        uint8 u8SourceEndPointId,
        uint8 u8DestinationEndPointId,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber);
```

Description This function can be used on an Appliance Statistics cluster server to send an unsolicited 'Statistics Available' message to a cluster client. The function is an alternative to **eCLD_ASCLogQueueResponseORStatisticsAvailableSend()**.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the message. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which to send the message. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId* Number of the endpoint on the remote node to which the message is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress* Pointer to a structure holding the address of the node to which the message is sent
- *pu8TransactionSequenceNumber* Pointer to a location to receive the Transaction Sequence Number (TSN) of the message

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_ASCLogNotificationORLogResponseSend

```
teZCL_Status eCLD_ASCLogNotificationORLogResponseSend(
        uint8 u8SourceEndPointId,
        uint8 u8DestinationEndPointId,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        teCLD_ApplianceStatistics_ServerCommandId
eCommandId,
        tsCLD_ASC_LogNotificationORLogResponsePayload
*psPayload);
```

Description This function can be used on an Appliance Statistics cluster server to send a 'Log Response' message (in reply to a 'Log Request' message) or an unsolicited 'Log Notification' message to a cluster client.

The command to be sent must be specified as one of:

- E_CLD_APPLIANCE_STATISTICS_CMD_LOG_NOTIFICATION
- E_CLD_APPLIANCE_STATISTICS_CMD_LOG_RESPONSE

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the message. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which to send the message. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId* Number of the endpoint on the remote node to which the message is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress* Pointer to a structure holding the address of the node to which the message is sent
- *pu8TransactionSequenceNumber* Pointer to a location to receive the Transaction Sequence Number (TSN) of the message
- *eCommandId* Enumeration indicating the command to be sent (see above and Section 48.8.3)
- *psPayload* Pointer to structure containing payload for message (see Section 48.9.3)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Parent topic: Functions

eCLD_ASCLogNotificationSend

```
teZCL_Status eCLD_ASCLogNotificationSend(
        uint8 u8SourceEndPointId,
        uint8 u8DestinationEndPointId,
        tsZCL_Address *psDestinationAddress,
        uint8 *pu8TransactionSequenceNumber,
        tsCLD_ASC_LogNotificationORLogResponsePayload
*psPayload);
```

Description This function can be used on an Appliance Statistics cluster server to send an unsolicited 'Log Notification' message to a cluster client. The function is an alternative to **eCLD_ASCLogNotificationORLogResponseSend()**.

You are required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the message. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndPointId* Number of the local endpoint through which to send the message. This parameter is used both to send the message and to identify the instance of the shared structure holding the required attribute values
- *u8DestinationEndPointId* Number of the endpoint on the remote node to which the message is sent. This parameter is ignored when sending to address types eZCL_AMBOUND and eZCL_AMGROUP
- *psDestinationAddress* Pointer to a structure holding the address of the node to which the message is sent
- *pu8TransactionSequenceNumber* Pointer to a location to receive the Transaction Sequence Number (TSN) of the message
- *psPayload* Pointer to structure containing payload for message (see Section 48.9.3)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_INVALID_VALUE

Return codes The Appliance Statistics cluster functions use the ZCL return codes, listed in Section 7.2.

Parent topic:*Appliance Statistics Cluster*

Enumerations

'Attribute ID' enumerations The following structure contains the enumerations used to identify the attributes of the Appliance Statistics cluster.

```
typedef enum PACK
{
    E_CLD_APPLIANCE_STATISTICS_ATTR_ID_LOG_MAX_SIZE = 0x0000,
    E_CLD_APPLIANCE_STATISTICS_ATTR_ID_LOG_QUEUE_MAX_SIZE
} teCLD_ApplianceStatistics_Cluster_AttrID;
```

Parent topic: Enumerations

'Client Command ID' enumerations The following enumerations are used in commands issued on a cluster client.

```
typedef enum PACK
{
    E_CLD_APPLIANCE_STATISTICS_CMD_LOG_REQUEST = 0x00,
    E_CLD_APPLIANCE_STATISTICS_CMD_LOG_QUEUE_REQUEST
} teCLD_ApplianceStatistics_ClientCommandId;
```

The above enumerations are described in the table below.

Enumeration	Description
E_CLD_APPLIANCE_STATISTICS_CMD_LOG_REQUEST	'Log Request' message
E_CLD_APPLIANCE_STATISTICS_CMD_LOG_QUEUE_REQUEST	'Log Queue Request' message

Parent topic: Enumerations

'Server Command ID' enumerations The following enumerations are used in commands issued on a cluster server.

```
typedef enum PACK
{
    E_CLD_APPLIANCE_STATISTICS_CMD_LOG_NOTIFICATION = 0x00,
    E_CLD_APPLIANCE_STATISTICS_CMD_LOG_RESPONSE,
    E_CLD_APPLIANCE_STATISTICS_CMD_LOG_QUEUE_RESPONSE,
    E_CLD_APPLIANCE_STATISTICS_CMD_STATISTICS_AVAILABLE
} teCLD_ApplianceStatistics_ServerCommandId;
```

The above enumerations are described in the table below.

Enumeration	Description
E_CLD_APPLIANCE_STATISTICS_CMD_LOG_NOTIFICATION	A 'Log Notification' message
E_CLD_APPLIANCE_STATISTICS_CMD_LOG_RESPONSE	A 'Log Response' message
E_CLD_APPLIANCE_STATISTICS_CMD_LOG_QUEUE_RESPONS	A 'Log Queue Response' message
E_CLD_APPLIANCE_STATISTICS_CMD_STATISTICS_AVAILABL	A 'Statistics Available' message

Parent topic: Enumerations

Parent topic:*Appliance Statistics Cluster*

Structures

tsCLD_ApplianceStatisticsCallBackMessage For an Appliance Statistics event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsCLD_ApplianceStatisticsCallBackMessage structure:

```
typedef struct
{
    uint8    u8CommandId;
    union
    {
      tsCLD_ASC_LogNotificationORLogResponsePayload
                          *psLogNotificationORLogResponsePayload;
      tsCLD_ASC_LogQueueResponseORStatisticsAvailablePayload
                          *psLogQueueResponseORStatisticsAvailabePayload;
      tsCLD_ASC_LogRequestPayload *psLogRequestPayload;
    } uMessage;
} tsCLD_ApplianceStatisticsCallBackMessage;
```

where:

- u``8CommandId indicates the type of Appliance Statistics command that has been received, one of:
  - E_CLD_APPLIANCE_STATISTICS_CMD_LOG_REQUEST
  - E_CLD_APPLIANCE_STATISTICS_CMD_LOG_QUEUE_REQUEST
  - E_CLD_APPLIANCE_STATISTICS_CMD_LOG_NOTIFICATION
  - E_CLD_APPLIANCE_STATISTICS_CMD_LOG_RESPONSE
  - E_CLD_APPLIANCE_STATISTICS_CMD_LOG_QUEUE_RESPONSE
  - E_CLD_APPLIANCE_STATISTICS_CMD_STATISTICS_AVAILABLE
- u``Message is a union containing the command payload as one of (depending on the value of u8CommandId):
  - psLogNotificationORLogResponsePayload is a pointer to the payload of a 'Log Notification' or 'Log Response' message (see Section48.9.3)
  - psLogQueueResponseORStatisticsAvailabePayload is a pointer to the payload of a 'Log Queue Response' or 'Statistics Available' message (see Section 48.9.4)
  - psLogRequestPayload is a pointer to the payload of a 'Log Request' message (see Section 48.9.2)

Parent topic: Structures

tsCLD_ASC_LogRequestPayload This structure contains the payload for the 'Log Request' message.

```
typedef struct
{
    zuint32    u32LogId;
} tsCLD_ASC_LogRequestPayload;
```

where u32LogId is the identifier of the data log being requested.

Parent topic: Structures

tsCLD_ASC_LogNotificationORLogResponsePayload This structure contains the payload for the 'Log Notification' and 'Log Response' messages.

```
typedef struct
{
    zutctime     utctTime;
    zuint32      u32LogId;
    zuint32      u32LogLength;
    uint8       *pu8LogData;
} tsCLD_ASC_LogNotificationORLogResponsePayload;
```

where:

- utctTime is the UTC time at which the reported log was produced
- u32LogId is the identifier of the reported log
- u32LogLength is the length, in bytes, of the reported log
- pu8LogData is a pointer to an area of memory to receive the data of the reported log

Parent topic: Structures

tsCLD_ASC_LogQueueResponseORStatisticsAvailablePayload This structure contains the payload for the 'Log Queue Response' and 'Statistics Available' messages.

```
typedef struct
{
    zuint8      u8LogQueueSize;
    zuint32    *pu32LogId;
} tsCLD_ASC_LogQueueResponseORStatisticsAvailablePayload;
```

where:

- u8LogQueueSize indicates the number of logs currently in the log queue
- pu32LogId is a pointer to an area of memory to receive the sequence of 32-bit log IDs of the logs in the queue

Parent topic: Structures

tsCLD_LogTable This structure is used to store the details of a data log.

```
typedef struct
{
    zutctime     utctTime;
    uint32       u32LogID;
    uint8        u8LogLength;
    uint8       *pu8LogData;
} tsCLD_LogTable;
```

where:

- utctTime is the UTC time at which the log was produced
- u32LogId is the identifier of the log
- u32LogLength is the length, in bytes, of the log
- pu8LogData is a pointer to an area of memory to receive the data of the log

Parent topic: Structures

tsCLD_ApplianceStatisticsCustomDataStructure The Appliance Statistics cluster requires extra storage space to be allocated to be used by internal functions. The structure definition for this storage is shown below:

```
typedef struct
{
    tsZCL_ReceiveEventAddress sReceiveEventAddress;
    tsZCL_CallBackEvent sCustomCallBackEvent;
    tsCLD_ApplianceStatisticsCallBackMessage sCallBackMessage;
#if (defined CLD_APPLIANCE_STATISTICS) && (defined APPLIANCE_STATISTICS_SERVER)
    tsCLD_LogTable asLogTable[CLD_APPLIANCE_STATISTICS_ATTR_LOG_QUEUE_MAX_SIZE];
#endif
} tsCLD_ApplianceStatisticsCustomDataStructure;
```

The fields are for internal use and no knowledge of them is required.

Parent topic: Structures

Parent topic:*Appliance Statistics Cluster*

Compile-time options This section describes the compile-time options that may be enabled in the **zcl_options.h** file of an application that uses the Appliance Statistics cluster.

To enable the Appliance Statistics cluster in the code to be built, it is necessary to add the following line to the file:

```
#define CLD_APPLIANCE_STATISTICS
```

In addition, to enable the cluster as a client or server, it is also necessary to add one of the following lines to the same file:

```
#define APPLIANCE_STATISTICS_SERVER
#define APPLIANCE_STATISTICS_CLIENT
```

The Appliance Statistics cluster contains macros that may be optionally specified at compile-time by adding some or all the following lines to the **zcl_options.h** file.

Global Attributes Add this line to define the value (n) of the Cluster Revision attribute:

```
#define CLD_APPLIANCE_STATISTICS_CLUSTER_REVISION <n>
```

The default value is 1, which corresponds to the revision of the cluster in the ZCL r6 specification (see Section 2.4).

Maximum Log Size Add this line to configure the maximum size n, in bytes, of a data log:

```
#define CLD_APPLIANCE_STATISTICS_ATTR_LOG_MAX_SIZE n
```

The default value is 70 bytes, which is the upper limit on this value, and n must therefore not be greater than 70.

The same value must be defined on the cluster server and client.

Maximum Log Queue Length Add this line to configure the maximum number of logs n in a log queue:

```
#define CLD_APPLIANCE_STATISTICS_ATTR_LOG_QUEUE_MAX_SIZE n
```

The default value is 15, which is the upper limit on this value, and n must therefore not be greater than 15.

The same value must be defined on the cluster server and client.

Enable Insertion of UTC Time Add this line to enable the application to insert UTC time data into logs:

```
#define CLD_APPLIANCE_STATISTICS_ATTR_LOG_QUEUE_MAX_SIZE n
```

Disable APS Acknowledgements for Bound Transmissions Add this line to disable APS acknowledgements for bound transmissions from this cluster:

```
#define CLD_ASC_BOUND_TX_WITH_APS_ACK_DISABLED
```

Parent topic:*Appliance Statistics Cluster*

Part XII: Over-The-Air Upgrade This part comprises only one chapter:

- *Chapter 49* details the **OTA (Over-the-Air) Upgrade** cluster

OTA Upgrade cluster This chapter describes the Over-The-Air (OTA) Upgrade cluster. The OTA Upgrade cluster has a Cluster ID of 0x0019.

Note: This chapter assumes that the ZigBee 3.0 network consists of nodes which contain only one processor - such as a JN518x, K32W041, K32W061, MCXW71, or MCXW72 microcontroller. However, the OTA Upgrade cluster can also be used with dual-processor nodes (containing a JN518x, K32W041, K32W061, MCXW71, MCXW72 device and a coprocessor), as described in *Appendix F*.

Overview The Over-The-Air (OTA) Upgrade cluster provides the facility to upgrade (or downgrade or re-install) application software on the nodes of a ZigBee PRO network by:

1. Distributing the replacement software through the network (over the air) from a designated node.
2. Updating the software in a node with minimal interruption to the operation of the node.

The OTA Upgrade cluster acts as a server on the node that distributes the software and as a client on the nodes that receive software updates from the server. The cluster server receives the software from outside the network.

An application that uses the OTA Upgrade cluster must include the header files **zcl_options.h** and **OTA.h**.

The OTA Upgrade cluster is enabled by defining CLD_OTA in the **zcl_options.h** file. Further compile-time options for the OTA Upgrade cluster are detailed in Section 49.13.

When including the OTA Upgrade facility in your application, you should increase the CPU stack size from the default value (as described in Section 49.5).

Parent topic:*OTA Upgrade cluster*

OTA Upgrade Images in Internal Flash Memory This section provides guidance on how to organize Over-The-Air (OTA) upgrade images in internal Flash memory on the target node (OTA Upgrade client). The OTA Upgrade cluster is described in *Chapter 49*.

By default, OTA upgrade images are downloaded to a Flash memory device that is internal to the device of the OTA Upgrade client. However, the images can optionally be downloaded directly to devices internal Flash memory - this is enabled using the compile-time option, OTA_INTERNAL_STORAGE (see Section 49.13).

The function **eOTA_AllocateEndpointOTASpace()** is used in the application to allocate locations in Flash memory to store application images as part of the OTA upgrade process. The OTA code then uses these locations to store the upgrade image before switching to it, after validation.

There are two issues relating to OTA upgrade and Flash memory remapping:

- Whether the size of the OTA upgrade binary file is larger than the previous version, such that it must use another sector
- Where in the memory space the OTA image is written to

Consider the following cases.

We have a 154 KB image (5 sectors) and download a new image of the same size, starting at sector 8:

Case 1 (Sector 8)

Logical Sector	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Physical Sector	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Contents	Running image					Empty			New image					Empty		

When we switch to the new image, the physical sectors are moved in the memory map by the bootloader so that the new image becomes the running image and the previous running image becomes the old image. Only the sectors that must be moved are actually moved by the bootloader, and the other sectors are left alone:

Case 2

Logical Sector	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Physical Sector	8	9	10	11	12	5	6	7	0	1	2	3	4	13	14	15
Contents	New running image					Empty			Old image					Empty		

If we now download a further new image that is 161KB (6 sectors) in size, it would replace the old running image and be placed into logical sectors 8 to 13, which are physical sectors 0, 1, 2, 3, 4 and 13. However, this new image is then unusable because the physical sectors are not contiguous and the bootloader does not take this into account when it remaps the memory (if the new image was less than 160KB, there would be no problem).

The simple solution to this problem is to replace the remapping that the bootloader has chosen with our own remapping in which logical sector 13 becomes physical sector 5, thus allowing the new image to be stored in contiguous physical sectors (0 to 5).

Case 3

Logical Sector	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Physical Sector	8	9	10	11	12	13	14	15	0	1	2	3	4	5	6	7
Contents	Running image					Empty			New image						Empty	

However, this does not leave any space for permanent data and it also assumes that the new image is stored at logical sector 8.

You may choose to put the new image anywhere in the Flash memory (ZigBee allows this to be configured, and a user-developed solution is free to do what it requires). So you need to adjust the remapping to match. For example, if the OTA image was placed at logical sector 7:

Case 4

Logical Sector	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Physical Sector	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Contents	Running image					Empty		New image					Empty			

The purpose of this is to leave some sectors at the end of Flash memory for permanent data (otherwise you could always start the OTA image at sector 8).

In such cases, the sensible approach is to:

1. Calculate how much permanent data space is required and reserve the end sectors for this data.
2. Divide the remaining space into two equal blocks of sectors
3. Configure the OTA upgrade to start at the beginning of the second block of sectors.
4. Force the remapping to swap the two blocks, regardless of the actual image size.

Consider the example in which a user wants 64KB for permanent data, which requires 2 sectors. This leaves 14 sectors for applications, so we have two blocks of 7 sectors for each application (even though the application may be smaller than this):

Case 5

Logical Sector	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Physical Sector	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Contents	Running image					Empty		New image					Empty		Data	

To avoid any problem with the new image growing and needing 6 sectors rather than 5 sectors, we force the remapping to swap all 7 sectors over:

Logical Sector	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Physical Sector	7	8	9	10	11	12	13	0	1	2	3	4	5	6	14	15
Contents	New running image					Empty		Old image					Empty		Data	

Case 6

This leaves sectors 14 and 15 in a fixed location.

The code to achieve this is as follows:

```
`    if (u8CurrentImageSector > 0)`
`    { `
`      /* Remapping will not affect the current running image,`
`         which was already running in a continuous block at the base `
`         application Flash address */ `
`      vREG_SysWrite(REG_SYS_FLASH_REMAP,  0x0dcba987); `
`      vREG_SysWrite(REG_SYS_FLASH_REMAP2, 0xfe654321);`
`    }`
```

Parent topic:*OTA Upgrade cluster*

OTA Upgrade Cluster structure and attributes The attributes of the OTA Upgrade cluster are contained in the following structure, which is located only on cluster clients:

```
typedef struct
{
#ifdef OTA_CLIENT
    uint64 u64UgradeServerID;
    uint32 u32FileOffset;
    uint32 u32CurrentFileVersion;
    uint16 u16CurrentStackVersion;
    uint32 u32DownloadedFileVersion;
    uint16 u16DownloadedStackVersion;
    uint8  u8ImageUpgradeStatus;
    uint16 u16ManfId;
    uint16 u16ImageType;
    uint16 u16MinBlockRequestDelay;
#endif
    uint16 u16ClusterRevision;
} tsCLD_AS_Ota;
```

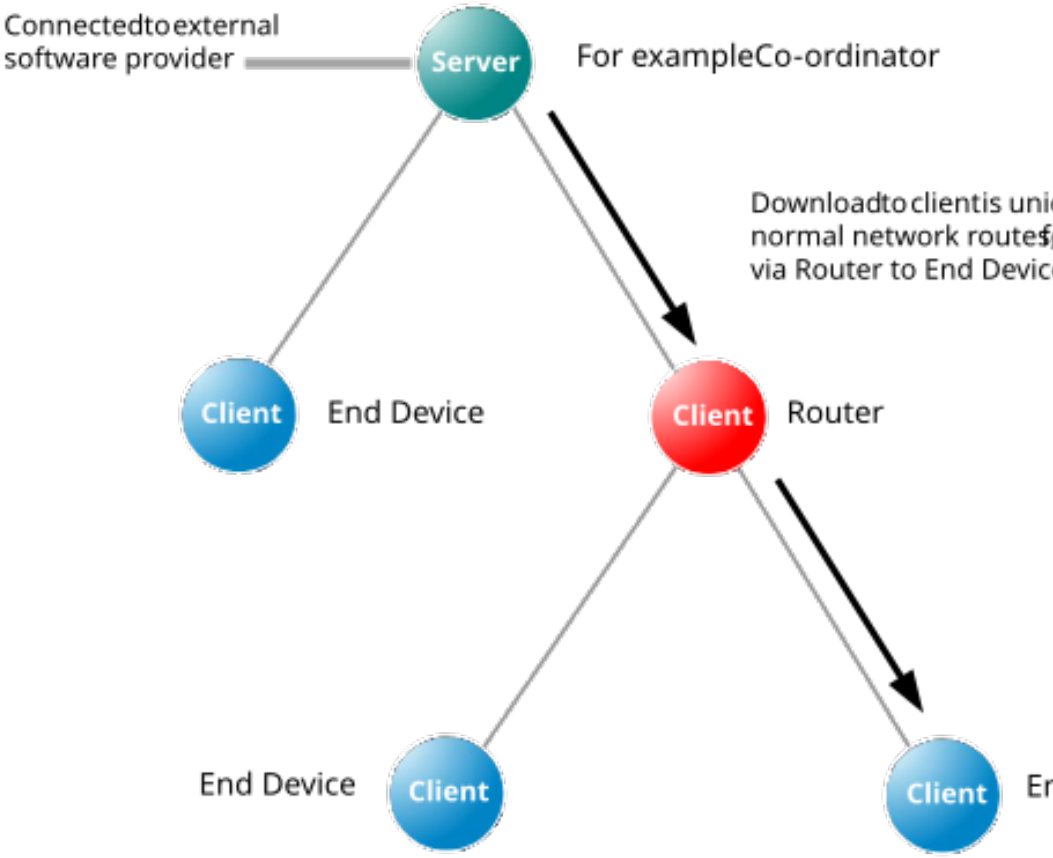
where:

- u64UgradeServerID contains the 64-bit IEEE/MAC address of the OTA Upgrade server for the client. This address can be fixed during manufacture or discovered during network formation/operation. If not pre-set, the default value is 0xFFFFFFFFFFFFFFFF. This attribute is mandatory.
- u32FileOffset contains the start address in local Flash memory of the upgrade image (that may be currently in transfer from server to client). This attribute is optional.
- u32CurrentFileVersion contains the file version of the firmware currently running on the client. This attribute is optional.
- u16CurrentStackVersion contains the version of the ZigBee stack currently running on the client. This attribute is optional.
- u32DownloadedFileVersion contains the file version of the downloaded upgrade image on the client. This attribute is optional.

- u16DownloadedStackVersion contains the version of the ZigBee stack for which the downloaded upgrade image was built. This attribute is optional.
- u8ImageUpgradeStatus contains the status of the client device in relation to image downloads and upgrades. This attribute is mandatory and the possible values are shown in the table below.

u8ImageUp	Status	Notes
0x00	Normal	Has not participated in a download/upgrade or the previous download/upgrade was unsuccessful
0x01	Download in progress	Client is requesting and successfully receiving blocks of image data from server
0x02	Download complete	All image data received and image saved to memory
0x03	Waiting to upgrade	Waiting for instruction from server to upgrade from the saved image
0x04	Count down	Server instructs the Client to count down to start of upgrade
0x05	Wait for more	Client is waiting for further upgrade image(s) from server - relevant to multi-processor devices, where each processor requires a different image
0x06 - 0xFF	Reserved	-

- u16ManfId contains the device's manufacturer code, assigned by the ZigBee Alliance. This attribute is optional.
- u16ImageType contains an image type identifier for the upgrade image that is currently being downloaded to the client or waiting on the client for the upgrade process to begin. When neither of these cases apply, the attribute is set to 0xFFFF. This attribute is optional.
- u16MinBlockRequestDelay is the minimum time, in seconds, that the local client must wait between submitting consecutive block requests to the server during an image download. It is used by the 'rate limiting' feature to control the average download rate to the client. The attribute can take values in the range 0 to OTA_BLOCK_REQUEST_DELAY_MAX_VALUE seconds, where this upper limit can be defined in the **zcl_options.h** file (see Section 49.13) - if undefined, its default value is 5 seconds. The value 0x0000 (default) indicates that the download can be performed at the full rate with no minimum delay between block requests. This attribute is optional.
- u16ClusterRevision is a mandatory attribute that specifies the revision of the cluster specification on which this cluster instance is based. The cluster specification in the ZCL r6 corresponds to a cluster revision of 1. The value is incremented by one for each subsequent revision of the cluster specification. This attribute is also described in Section 2.4.



Thus, the OTA Upgrade cluster structure contains only two mandatory elements, u64UgradeServerID and u8ImageUpgradeStatus. The remaining elements are optional, each being enabled/disabled through a corresponding macro defined in the **zcl_options.h** file (see Section 49.13).

Parent topic:*OTA Upgrade cluster*

Basic Principles Over-the-Air (OTA) Upgrade allows the application software on a ZigBee node to be upgraded with minimal disruption to node operation and without physical intervention by the user/installer. For example, there is no need for a cabled connection to the node. Using this technique, the replacement software is distributed to nodes through the wireless network, allowing application upgrades to be performed remotely.

The software upgrade is performed from a node which acts as an OTA Upgrade cluster server, which is able to obtain the upgrade software from an external source. The nodes that receive the upgrade software act as OTA Upgrade cluster clients. The server node and client node(s) may be from different manufacturers.

The download of an application image from the server to the network is done on a per client basis and follows normal network routes (including routing via Routers). This is illustrated in the figure below.

OTA Download Example |

The upgrade application is downloaded into Flash memory internal to the device on the client node. Note that the upper section of Flash memory should normally be reserved for persistent data storage - for example, in an 8-sector Flash device, Sector 7 is used for persistent data storage, leaving Sectors 0-6 available to store application software.

The requirements of the devices which act as the OTA Upgrade cluster server and clients are detailed in the sub-sections below. See Connectivity Framework Reference Manual for details of the Non-Volatile Memory Manager (NVM).

OTA Upgrade Cluster Server The OTA Upgrade cluster server is a network node that distributes application upgrades to other nodes of the network (as well as performing its own functions). The server must, therefore, be connected to the provider of the upgrade software. The server would also usually be the Coordinator of the ZigBee network.

The server may need to store different upgrade images for different nodes (possibly from different manufacturers) and must have ample Flash memory space for this purpose. Therefore, the server must keep a record of the software required by each client in the network and the software version number that the client is currently on. When a new version of an application image becomes available, the server may notify the relevant client(s) or respond to poll requests for software upgrades from the clients (see Section 49.4.2 below).

Parent topic: Basic Principles

OTA Upgrade Cluster Client An OTA Upgrade cluster client is a node which receives software upgrades from the server and can be any type of node in a ZigBee network. However, an End Device client which sleeps is not always available to receive notifications of software upgrades from the server and must therefore, periodically poll the server for upgrades. In fact, all types of client can poll the server, if preferred.

During a software download from server to client, the upgrade image is transferred over the air in a series of data blocks. It is the responsibility of the client (and not the server) to keep track of the blocks received and then to validate the final image. The upgrade image is initially saved to the relevant sectors of Flash memory on the client. There must be enough Flash memory space on the client to store the upgrade image and the image of the currently running software.

An OTA upgrade image is downloaded into a Flash memory of the device, utilizing Flash sectors is currently not used for the running image.

Parent topic: Basic Principles

Parent topic:*OTA Upgrade cluster*

Application Requirements In order to implement OTA upgrades, the application images for the server and clients must be designed and built according to certain requirements.

These requirements include the following:

- Inclusion of the header files **zcl_options.h** and **OTA.h**
- Inclusion of the relevant #defines in the file **zcl_options.h**, as described in Section 49.13
- Specific application initialization requirements, as outlined in Section 49.6
- Use of the Non-Volatile Memory Manager (NVM) to preserve context data, as outlined in Section 49.8.5
- Organization of Flash memory, as outlined in Section 49.8.6
- It is necessary to remove references to the Certicom security certificate, as indicated in Section 49.13

Note: Some of above requirements differ between the server image, the first client image and client upgrade images. These differences are pointed out, where relevant, in Section 49.6 and Section 49.8.

In addition, you should increase the CPU stack size from the default value. With OTA Upgrade, the recommended stack size is 6000 bytes. This can be done by including the following line in your application makefile:

```
___stack_size = 6000;
```

Parent topic:*OTA Upgrade cluster*

Initialization Initialization of the various software components used with the OTA Upgrade cluster (see Section 49.5) must be performed in a particular order in the application code. The initialization could be incorporated in a function **APP_vInitialise()**, as is the case in the NXP *ZigBee PRO Application Template (JN-AN-1248)*.

Initialization must be performed in the following order:

1. The NVM module must first be initialized using the function **NvModuleInit()**.
2. The persistent data record(s) should then be initialized using the function and registered **NVM_RegisterDataSet()**.

3. The ZigBee PRO stack must now be started by first calling the function **ZPS_vSetOverrideLocalMacAddress()** to over-ride the existing MAC address, followed by **ZPS_eAplAfInit()** to initialize the Application Framework and then **ZPS_eAplZdoStartStack()** to start the stack.
4. The ZCL initialization function, **eZCL_Initialise()**, can now be called. An OTA Upgrade cluster instance should then be created using **eOTA_Create()**, followed by a call to **eOTA_UpdateClientAttributes()** or **eOTA_RestoreClientData()** on a client to initialize the cluster attributes.
5. The Flash programming of the OTA Upgrade cluster must now be initialized using the function **vOTA_FlashInit()**.
6. The required device endpoint(s) can now be registered (for example, a Simple Sensor device).
7. The function **eOTA_AllocateEndpointOTASpace()** must be called to allocate Flash memory space to an endpoint. The information provided to this function includes the numbers of the start sectors for storage of application images and the maximum number of sectors per image.
8. On the server, a set of client devices can be defined for which OTA upgrades are authorized - that is, a list of clients that are allowed to use the server for OTA upgrades. This client list is set up using the function **eOTA_SetServerAuthorisation()**.
9. For a client, a server must be found (provided this is a first-time start or a reboot with no persisted data, and so there is no record of a previous server address). This can be done by sending out a Match Descriptor Request using the function **ZPS_eAplZdpMatchDescRequest()**, described in the *ZigBee 3.0 Stack User Guide (JNUG3130)*. Once a server has been found, its address must be registered with the OTA Upgrade cluster using the function **eOTA_SetServerAddress()**.

The coding that is then required to implement OTA upgrade in the server and client applications is outlined in Section 49.7.

Parent topic:*OTA Upgrade cluster*

Implementing OTA Upgrade Mechanism The OTA upgrade mechanism is implemented in code as described below.

Note: The stack automatically handles part of an OTA upgrade and calls some of the OTA functions. However, if preferred, the application can handle all aspects of an OTA upgrade and filter all OTA data indications. In this case, the application must call all the relevant OTA functions (these are indicated below).

1. On the server, when a new client image is available for download, the function **eOTA_NewImageLoaded()** should be called to request the OTA Upgrade cluster to validate the image.

- Then, optionally, the function **eOTA_SetServerParams()** can be called to set the server parameter values for the new image. Otherwise, the default parameter values will be used.

2. The server must then notify the relevant client(s) of the availability of the new image. The notification method depends on the ZigBee node type of the client:

- **Coordinator or Router client:** The server can notify the Coordinator or a Router client directly by sending an Image Notify message to the client through a call to the function **eOTA_ServerImageNotify()**. This message can be unicast, multicast or broadcast. On arrival at a client, this message will trigger an Image Notify event. If the new software is required, the client can request the upgrade image by sending a Query Next Image Request to the server through a call to **eOTA_ClientQueryNextImageRequest()**.
- **All clients:** The server cannot notify an End Device client directly, since the End Device may be asleep when a notification message is sent. Therefore, an End Device client must

poll the server periodically (during wake periods) in order to establish whether new software is available. In fact, any client can implement polling of the server. The client does this by sending a Query Next Image Request to the server through a call to the function **eOTA_ClientQueryNextImageRequest()**.

  - On arrival at the server, the Query Next Image Request message triggers a Query Next Image Request event.

3. The server automatically replies to the request with a Query Next Image Response (the application can also send this response by calling the function **eOTA_ServerQueryNextImageResponse()**). The contents of this response message depend on whether the client is using notifications or polling:

- **Coordinator or Router client (notifications):** The response contains details of the upgrade image, such as manufacturer, image type, image size, and file version.
- **All clients (polling):** If upgrade software is available, the response reports success and the message contains details of the upgrade image, as indicated above. If no upgrade software is available, the response simply reports failure (the client must then poll again later).

  - On arrival at the client, the Query Next Image Response message triggers a Query Next Image Response event.

4. The OTA Upgrade cluster on the client now automatically requests the upgrade image one block at a time by sending an Image Block Request to the server (this request can also be sent by the application through a call to the function **eOTA_ClientImageBlockRequest()**). The maximum size of a block and the time interval between requests can both be configured in the header file **zcl-_options.h** - see Section 49.13.

- On arrival at the server, the Image Block Request message triggers an Image Block Request event.

5. The server automatically responds to each block request with an Image Block Response containing a block of data (the application can also send this response by calling the function **eOTA_ServerImageBlockResponse()**).

- On arrival at the client, the Image Block Response message triggers an Image Block Response event.

6. The client determines when the entire image has been received (by referring to the image size that was quoted in the Query Next Image Response before the download started). Once the final block of image data has been received, the client application should transmit an Upgrade End Request to the server (that is, by calling **eOTA_HandleImageVerification()**).

- This Upgrade End Request may report success or an invalid image. In the case of an invalid image, the image will be discarded by the client, which may initiate a new download of the image by sending a Query Next Image Request to the server.
- On arrival at the server, the Upgrade End Request message triggers an Upgrade End Request event.

Note: An Upgrade End Request may also be sent to the server during a download in order to abort the download.

7. The server replies to the request with an Upgrade End Response containing an instruction of when the client should use the downloaded image to upgrade the running software on the node (the message contains both the current time and the upgrade time, and hence an implied delay).

- On arrival at the client, the Upgrade End Response message triggers an Upgrade End Response event.

8. The client will then count down to the upgrade time (in the Upgrade End Response) and on reaching it, start the upgrade. If the upgrade time has been set to an indefinite value (represented by 0xFFFFFFFF), the client should poll the server for an Upgrade Command at least once per minute and start the upgrade once this command has been received.

9. Once triggered on the client, the upgrade process proceeds as follows (although the details will be manufacturer-specific):

a) A reboot of the device is initiated causing the default bootloader to run.

b) The bootloader scans through Flash looking for various image headers, including the running one and the one received via OTA. If the OTA image in newer, indicated by version number in the header, this is selected as the new running image.

Note: The client automatically invalidates the existing image and validates the new upgrade image once the allotted upgrade time is reached.

c) The new software image is then executed.

Query Jitter The 'query jitter' mechanism can be used to prevent a flood of replies to an Image Notify broadcast or multicast (Step 2 above). The server includes a number, n, in the range 1-100 in the notification. If interested in the image, the receiving client generates a random number in the range 1-100. If this number is greater than n, the client discards the notification, otherwise it responds with a Query Next Image Request. This results in only a fraction of interested clients responding to each broadcast/multicast and therefore helps to avoid traffic congestion.

Parent topic:*OTA Upgrade cluster*

Ancillary Features and Resources for OTA Upgrade As indicated in Section 49.5, in order to implement OTA upgrades, a number of other software features and resources are available. These are described in the sub-sections below.

Rate Limiting During busy periods when the OTA Upgrade server is downloading images to multiple clients, it is possible to prevent OTA traffic congestion by limiting the download rates to individual clients. This is achieved by introducing a minimum time-delay between consecutive Image Block Requests from a client - for example, if this delay is set to 500 ms for a particular client then after sending one block request to the server, the client must wait at least 500 ms before sending the next block request. This has the effect of restricting the average OTA download rate from the server to the client.

This 'block request delay' can be set to different values for different clients. This allows OTA downloads to be prioritized by granting more download bandwidth to some clients than to others. This delay for an individual client can also be modified by the server during a download, allowing the server to react in real-time to varying OTA traffic levels.

The implementation of the above rate limiting is described below and is illustrated in the Figure "Example of Rate limiting exchange" below.

'Block Request Delay' Attribute The download rate to an individual client is controlled using the optional attribute u16MinBlockRequestDelay of the OTA Upgrade cluster (see Section 49.3) on the client. This attribute contains the 'block request delay' for the client (described above), in milliseconds, and must be enabled on the client only (see below).

Note: The u16MinBlockRequestDelay attribute is the minimum time-interval between block requests. The application on the client can implement longer intervals between these requests (a slower download rate), if required.

Enabling the Rate Limiting Feature In order to use the rate limiting feature during an OTA upgrade, the macro OTA_CLD_ATTR_REQUEST_DELAY must be defined in the **zcl_options.h** file for both the participating client(s). This enables the u16MinBlockRequestDelay attribute in the OTA Upgrade cluster structure.

Implementation in the Server Application The application on the OTA Upgrade server device can control the OTA download rate to an individual client by remotely setting the value of the 'block request delay' attribute on the client. However, first the server must determine whether the client supports the rate limiting feature. The server can do this in either of two ways:

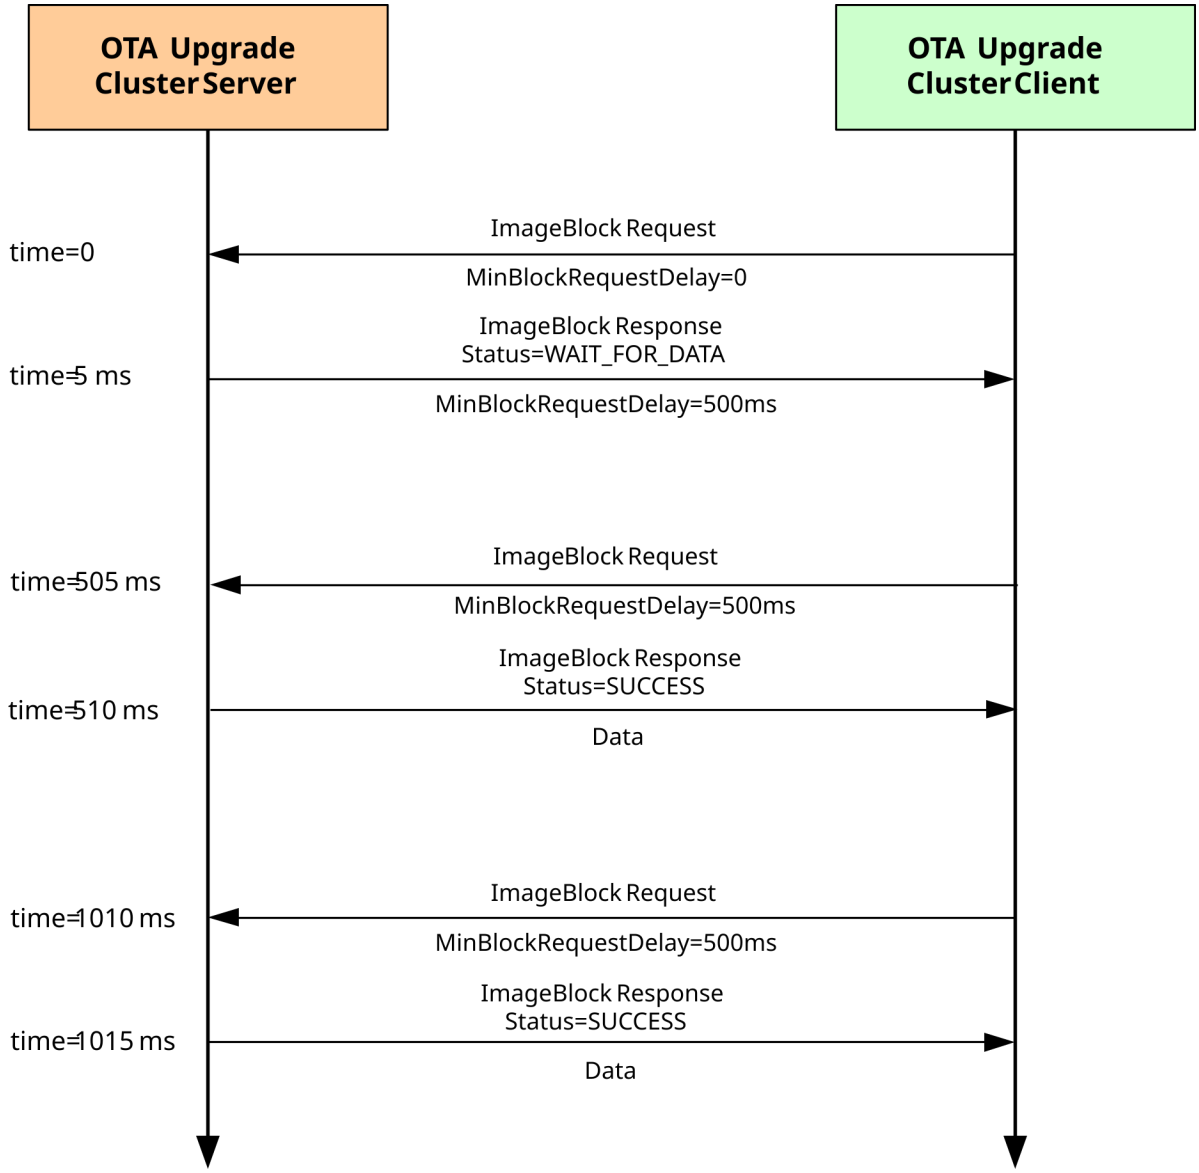
- It can attempt to read the u16MinBlockRequestDelay attribute in the OTA Upgrade cluster on the client - if rate limiting is not enabled on the client, this read will yield an error.
- It can check whether the first Image Block Request received from the client contains a 'block request delay' field - if present, this value is passed to the application in the event E_CLD_OTA_COMMAND_BLOCK_REQUEST.

The server can change the value of the 'block request delay' attribute on the client at any time, even during a download. To do this, the server includes the new attribute value in an Image Block Response with status OTA_STATUS_WAIT_FOR_DATA. This is achieved in the application code through a call to the function **eOTA_SetWaitForDataParams()** following an Image Block Request (indicated by an E_CLD_OTA_COMMAND_BLOCK_REQUEST event). The new attribute value specified in this function call is included in the subsequent Image Block Response and is automatically written to the OTA Upgrade cluster on the client.

The server may update the 'block request delay' attribute on a client multiple times during a download in order to react to changing OTA traffic conditions. If the server is downloading an image to only one client then it may choose to allow this download to proceed at the full rate (specified by a zero value of the attribute on the client). However, if two or more clients request downloads at the same time, the server may choose to limit their download rates (by setting the attribute to non-zero values on the clients). The download to one client can be given higher priority than other downloads by setting the attribute on this client to a lower value.

Implementation in the Client Application The application on the OTA Upgrade client device must control a millisecond timer (a timer with a resolution of one millisecond) to support rate limiting. This timer is used to time the delay between receiving an Image Block Response and submitting the next Image Block Request.

During an image download, a received Image Block Response with the status OTA_STATUS_WAIT_FOR_DATA may contain a new value for the 'block request delay' attribute (this type of response may arrive at the start of a download or at any time during the download). The client will automatically write this new value to the u16MinBlockRequestDelay attribute in the local OTA Upgrade cluster structure and will also generate the event E_ZCL_CBET_ENABLE_MS_TIMER (provided that the new attribute value is non-zero).



The E_ZCL_CBET_ENABLE_MS_TIMER event prompts the application to start the millisecond timer for a timed interval greater than or equal to the new value of the 'block request delay' attribute. The application can obtain this new attribute value (in milliseconds) from the event via:

```
sZCL_CallBackEvent.uMessage.u32TimerPeriodMs
```

The millisecond timer is started for a particular timed interval. The expiry of this timer is indicated by an E_ZCL_CBET_TIMER_MS event, which is handled as described in Section 3.2. The client will then send the next Image Block Request.

After sending an Image Block Request:

- If the client now generates an E_ZCL_CBET_DISABLE_MS_TIMER event, this indicates that the last of the Image Block Request (for the required image) has been sent and the application should disable the millisecond timer.
- Otherwise, the application must start the next timed interval (until the next request).
  Example of Rate limiting exchange

Parent topic: Ancillary Features and Resources for OTA Upgrade

Device-Specific File Downloads An OTA Ugrade client can request a file (from the server) that is specific to the client device. This file may contain non-firmware data such as security credentials, configuration data or log data. The process of making this request and receiving the file is described in the table below for both the client and server sides.

	On Client	On Server
1	Client application sends a Query Specific File Request to the server through a call to **eOTA_ClientQuerySpecificFileRequest()**.	
2		On arrival at the server, the Query Specific File Request triggers the event E_CLD_OTA_COMMAND_QUERY_SPECIFIC_FILE_REQUEST.
3		Server automatically replies to the request with a Query Specific File Response - the application can also send a response using **eOTA_ServerQuerySpecificFileResponse()**.
4	On arrival at the client, the Query Specific File Response triggers the event E_CLD_OTA_COMMAND_QUERY_SPECIFIC_FILE_	
5	Client obtains status from Query Specific File Response. If status is SUCCESS, the client automatically requests the device-specific file one block at a time by sending Image Block Requests to the server.	
6		On arrival at the server, each Image Block Request triggers an Image Block Request event.
7		Server automatically responds to each block request with an Image Block Response containing a block of device-specific file data.
8	After receiving each Image Block Response, the client generates the event E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_F	
9	A callback function is invoked on the client to handle the event and store the data block (it is the responsibility of the application to store the data in a convenient place).	
10	Client determines when the entire file has been received (by referring to the file size that was quoted in the Query Specific File Response before the download started). Once all the file blocks have been received:	

- E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_DL_COMPLETE event is generated by the client to indicate that the file transfer is complete.
- The file can optionally be verified by application.
- Client sends an Upgrade End Request to the server to indicate that the download is complete, where this request is the result of an application call to the function **eOTA_SpecificFileUpgradeEndRequest()**.

|| |**11**||On arrival at the server, the Upgrade End Request triggers an Upgrade End Request event.| |**12**||Server may reply to the Upgrade End Request with an Upgrade End Response containing an instruction of when the client should use the device-specific file (the message contains both the current time and the upgrade time, and hence an implied delay) - see Footnotes 1 and 2 below.| |**13**|On arrival at the client, the Upgrade End Response triggers an Upgrade End Response event - see Footnotes 1 and 2 below.|| |**14**|Client will then count down to the upgrade time (in the Upgrade End Response) and, on reaching it, will generate the event

E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_USE_NEW_FILE. Finally, it is the responsibility of the application to use device-specific file as appropriate.||

Footnotes

1. For a device-specific file download, it is not mandatory for the server to send an Upgrade End Response to the client. In the case of a client which has just finished retrieving a log file from the server, the Upgrade End Response may not be needed. However, if the client has just retrieved a file containing security credentials or configuration data, the Upgrade End Response may be needed to notify the client of when to apply the file. The decision of whether to send an Upgrade End Response for a device-specific file download is manufacturer-specific.

2. If an Upgrade End Response is not received from the server, the client will perform 3 retries to get the response. If it still does not receive a response, the client will generate the event E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_NO_UPGRADE_END_RESPONSE.

Parent topic: Ancillary Features and Resources for OTA Upgrade

Image Block Size and Fragmentation An OTA Upgrade image is normally requested by the OTA Upgrade client one block at a time. The ZigBee frame for the OTA transfer contains various header data as well as payload data and, for this reason, the payload data is limited to about 48 bytes. Therefore, to transfer one image block per frame, the block size must be restricted to 48 bytes or less. The maximum block size can be configured at compile-time through the OTA_MAX_BLOCK_SIZE define in the **zcl_options.h** file (see Section 49.13).

A block size of greater than 48 bytes can be used but the image block will need to be transferred across two or more ZigBee frames. In this case, fragmentation must be enabled in which the image block data that is assembled in an APDU (Application Protocol Data Unit) on the server is fragmented into multiple NPDUs (Network Protocol Data Unit) for OTA transfer, where one NPDU is transferred in a single ZigBee frame. Fragmentation is enabled on the OTA Upgrade server and client using network parameters of the ZigBee PRO stack, as follows:

- **On the server:** Set the parameter *Maximum Number of Transmitted Simultaneous Fragmented Messages* to a non-zero value to allow transmitted messages to be fragmented.
- **On the client:** Set the parameter *Maximum Number of Received Simultaneous Fragmented Messages* to a non-zero value to allow received fragmented messages to be re-assembled.

The network parameter values are set using the ZPS Configuration Editor and are described in the *ZigBee 3.0 Stack User Guide (JNUG3130)*.

Note: **Note:**The 48-byte limit on the payload data in a ZigBee frame is also applicable when image data is requested and transferred one page at a time (see Section 49.8.4). In this case, fragmentation may need to be enabled.

The maximum APDU size must always be greater than the size of an Image Block Response. It is set through the APDU *Size* parameter of the PDU Manager, where this parameter is amongst the Advanced Device Parameters that can be configured using the ZPS Configuration Editor.

Depending on the image block size, fragmentation is not always an efficient way of transferring image blocks, as the payload of the final NPDU fragment may contain little data and be mostly empty. For example, if the image block size is set to 64 bytes and fragmentation is enabled, each block is transferred in two ZigBee frames, the first may contain 48 bytes of data and the second may contain only 16 bytes of data, leaving 32 empty bytes in the payload. In contrast, if the block size is set to 48 bytes without fragmentation, two consecutive frames would carry 96 bytes of data, and the image transfer would require fewer frames. This is particularly important when transferring an application image to a battery-powered End Device that needs to conserve energy.

Parent topic: Ancillary Features and Resources for OTA Upgrade

Page Requests An OTA Upgrade client normally requests image data from the server one block at a time, by sending an Image Block Request when it is ready for the next block. The number of requests can be reduced by requesting the image data one page at a time, where a page may contain many blocks of data. Requesting data by pages reduces the OTA traffic and, in the case of battery-powered client device, extends battery life.

A page of data is requested by sending an Image Page Request to the server. This request contains a page size, which indicates the number of data bytes that should be returned by the server following the request (and before the next request is sent, if any). The server still sends the data one block at a time in Image Block Responses. The Image Page Request also specifies the maximum number of bytes that the client device can receive in any one OTA message and the block size must therefore not exceed this limit (in general, the page size should be a multiple of this limit).

It is the responsibility of the client to keep track of the amount of data so far received since the last Image Page Request was issued - this count is updated after each Image Block Response received. Once this count reaches the page size in the request, the client will issue the next Image Page Request (if the download is not yet complete).

During a download that uses page requests:

- If the client fails to receive one or more of the requested blocks then the next Image Page Request will request data starting from the offset which corresponds to the first missing block.
- If the client fails to receive all the blocks requested in an Image Page Request then the same request will be repeated up to two more times - if the requested data still fails to arrive, the client will switch to using Image Block Requests to download the remaining image data.

An Image Page Request also contains a 'response spacing' value. This indicates the minimum time-interval, in milliseconds, that the server should insert between consecutive Image Block Responses. If the client is a sleepy End Device, it may specify a long response spacing so that it can sleep between consecutive Image Block Responses, or it may specify a short response spacing so that it can quickly receive all blocks requested in a page and sleep between consecutive Image Page Requests.

The implementation of the above page requests in an application is described below. The OTA image download process using page requests is similar to the one described in Section 49.7, except the client submits Image Page Requests to the server instead of Image Block Requests.

Enabling the Page Requests Feature In order to use page requests, the macro OTA_PAGE_REQUEST_SUPPORT must be defined in the **zcl_options.h** file for the server and client.

In addition, values for the page size and response spacing can also be defined in this file for the client (if non-default values are required) - see below and Section 49.13.

Implementation in the Server Application The application on the OTA Upgrade server device must control a millisecond timer (a timer with a resolution of one millisecond) to support page requests. This timer is used to implement the 'response spacing' specified in an Image Page Request - that is, to time the interval between the transmissions of consecutive Image Block Responses (sent out in response to the Image Page Request).

When the server receives an Image Page Request, it will generate the event E_ZCL_CBET_ENABLE_MS_TIMER to prompt the application to start the millisecond timer for a timed interval equal in value to the 'response spacing' in the request. The application can obtain this value (in milliseconds) from the event via:

```
sZCL_CallBackEvent.uMessage.u32TimerPeriodMs
```

The millisecond timer is started for a particular timed interval. The expiry of this timer is indicated by an E_ZCL_CBET_TIMER_MS event, which is handled as described in Section 3.2. The server will then send the next Image Block Response.

After sending an Image Block Response:

- If the server now generates an E_ZCL_CBET_DISABLE_MS_TIMER event, this indicates that the last of the Image Block Responses (for the Image Page Request) has been sent and the application should disable the millisecond timer.
- Otherwise, the application must start the next timed interval (until the next response).

Implementation in the Client Application There is nothing specific to do in the client application to implement page requests. Provided that page requests have been enabled in the **zcl_options.h** file for the client (see above), page requests will be automatically implemented by the stack instead of block requests for OTA image downloads. The page size (in bytes) and response spacing (in milliseconds) for these requests can be specified through the following macros in the **zcl_options.h** file (see Section 49.13):

- OTA_PAGE_REQ_PAGE_SIZE
- OTA_PAGE_REQ_RESPONSE_SPACING

The default values are 512 bytes and 300 ms, respectively.

However, the client application can itself submit an Image Page Request to the server by calling the function **eOTA_ClientImagePageRequest()**. In this case, the page size and response spacing are specified in the Image Page Request payload structure as part of this function call.

The client handles the resulting Image Block Responses as described in Section 49.7 for standard OTA downloads.

Parent topic: Ancillary Features and Resources for OTA Upgrade

Persistent Data Management The OTA Upgrade cluster on a client requires context data to be preserved in non-volatile memory to facilitate a recovery of the OTA Upgrade status following a device reboot. The Non-Volatile Memory Manager (NVM) module should be used to perform this data saving and recovery. The NVM module is implemented as described in the *Connectivity Framework Reference Manual*.

Persistent data is normally be stored in the upper sector of the devices Flash memory. Thus, when the NVM module is initialized, these sectors should be specified (just these sectors should be managed by the NVM module).

When it needs to save context data, the OTA Upgrade cluster will generate the event E_CLD_OTA_INTERNAL_COMMAND_SAVE_CONTEXT, which will also contain the data to be saved. A user-defined callback function can then be invoked to perform the data storage using functions of the NVM module.

The OTA Upgrade cluster is implemented for an individual application/endpoint. Therefore, the NVM module should also be implemented per endpoint. The following code illustrates the reservation of memory space for persistent data per endpoint.

```
typedef struct
{
        uint8 u8Endpoints[APP_NUM_OF_ENDPOINTS];
        uint8 eState; // Current application state to re-instate
   tsOTA_PersistedData sPersistedData[APP_NUM_OF_ENDPOINTS];
} tsDevice;
PUBLIC tsDevice s_sDevice;
```

If a client is restarted and persisted data is available on the device, the OTA Upgrade cluster data should be restored using the function **eOTA_RestoreClientData()**.

Parent topic: Ancillary Features and Resources for OTA Upgrade

Flash Memory Organization Flash memory should be organized such that the application images are stored from Sector 0 and, if required, persistent data is stored in the final sectors.

The storage of applications and persistent data in Flash memory is described further below. Guidance on the organization of OTA upgrade applications in the devices internal Flash memory is also provided Appendix.

Application Images As part of application initialization (see Section 49.6), the OTA Upgrade cluster must be informed of the storage arrangements for application images in Flash memory. This is done through the function **eOTA_AllocateEndpointOTASpace()**, which applies to a specified endpoint (normally the endpoint of the application which calls the function). The information provided via this function includes:

- Start sector for each image that can be stored (specified through an array with one element per image). s
- Number of images for the endpoint (the maximum number of images per endpoint is specified in the **zcl_options.h** file - see Section 49.13)
- Maximum number of sectors per image
- Type of node (server or client)
- Public key for signed images

Persistent Data The storage of persistent data is handled by the NVM module (see Section 49.8.5) and the sector used is specified as part of the NVM initialization through **NvModuleInit()** - the final sector of Flash memory should be specified.

Parent topic: Ancillary Features and Resources for OTA Upgrade

Low-Voltage Flag An OTA Upgrade cluster client should not attempt to participate in an OTA upgrade if the supply voltage to the host hardware device is low (below the normal operating voltage for the device). On the device, sufficient voltage is required to write to the internal Flash There may be a number of reasons for a sudden drop in supply voltage - for example, the voltage on a battery-powered node may fall when the battery is near the end of its life.

The OTA Upgrade cluster incorporates a mechanism which, if enabled, stops the cluster client from sending Image Block Requests to the server when the local supply voltage becomes low. This mechanism allows the application to set a low-voltage flag which, when set, automatically suspends the block requests. When the flag is cleared, the block requests are automatically resumed.

If required, use of the low-voltage flag and associated mechanism must be enabled at compile-time by including the following line in the **zcl_options.h** file:

```
#define OTA_UPGRADE_VOLTAGE_CHECK
```

It is the responsibility of the application to check the supply voltage. This check is system-specific and may be performed periodically or using a voltage monitoring feature - for example, on the device, the Supply Voltage Monitor (SVM) can be used, which is described in the MCUXpresso SDK API Reference Manual.

The application can use the function **vOTA_SetLowVoltageFlag()** to configure the low-voltage flag. This function is detailed in Section 49.10.3.

When a low voltage is detected, the application should make the following function call to set the low-voltage flag and suspend Image Block Requests:

```
vOTA_SetLowVoltageFlag(TRUE);
```

When the voltage is restored to a normal level, the application should make the following function call to clear the low-voltage flag and resume Image Block Requests:

```
vOTA_SetLowVoltageFlag(FALSE);
```

Parent topic:*OTA Upgrade cluster*

OTA Upgrade events The events that can be generated on an OTA Upgrade cluster server or client are defined in the structure teOTA_UpgradeClusterEvents (see Section 49.12.2). The events are listed in the table below, which also indicates on which side of the cluster (server or client) the events can occur:

Cluster Side(s)	Event
Server	E_CLD_OTA_CO
E_CLD_OTA_COMMAND_BLOCK_REQUEST	
E_CLD_OTA_COMMAND_PAGE_REQUEST	
E_CLD_OTA_COMMAND_UPGRADE_END_REQUEST	
E_CLD_OTA_COMMAND_QUERY_SPECIFIC_FILE_REQUEST	
E_CLD_OTA_INTERNAL_COMMAND_SEND_UPGRADE_END_RESPONSE	
	E_CLD_OTA_IN
Client	E_CLD_OTA_CO
E_CLD_OTA_COMMAND_QUERY_NEXT_IMAGE_RESPONSE	
E_CLD_OTA_COMMAND_BLOCK_RESPONSE	
E_CLD_OTA_COMMAND_UPGRADE_END_RESPONSE	
E_CLD_OTA_COMMAND_QUERY_SPECIFIC_FILE_RESPONSE

OTA Upgrade events are treated as ZCL events. Thus, an event is received by the application, which wraps the event in a $\mathrm{tsZCL_CallBackEvent}$structure and passes it into the ZCL using the function **vZCL_EventHandler()** - for further details of ZCL event processing, refer to *Chapter 3*.

The above events are outlined in the sub-sections below.

Server-side Events

- **E_CLD_OTA_COMMAND_QUERY_NEXT_IMAGE_REQUEST**
  - This event is generated on the server when a Query Next Image Request is received from a client to enquire whether a new application image is available for download. The event may result from a poll request from the client or may be a consequence of an Image Notify message previously sent by the server. The server reacts to this event by returning a Query Next Image Response.
- **E_CLD_OTA_COMMAND_BLOCK_REQUEST**
  - This event is generated on the server when an Image Block Request is received from a client to request a block of image data as part of a download. The application reacts to this event by returning an Image Block Response containing a data block.
- **E_CLD_OTA_COMMAND_PAGE_REQUEST**
  - This event is generated on the server when an Image Page Request is received from a client to request a page of image data as part of a download.
- **E_CLD_OTA_COMMAND_UPGRADE_END_REQUEST**
  - This event is generated on the server when an Upgrade End Request is received from a client to indicate that the complete image has been downloaded and verified. The application reacts to this event by returning an Upgrade End Response.
- **E_CLD_OTA_COMMAND_QUERY_SPECIFIC_FILE_REQUEST**
  - This event is generated on the server when a Query Specific File Request is received from a client to request a particular application image. The server reacts to this event by returning a Query Specific File Response.
- **E_CLD_OTA_INTERNAL_COMMAND_SEND_UPGRADE_END_RESPONSE**
  - This event is generated on the server to notify the application that the stack is going to send an Upgrade End Response to a client. No specific action is required by the application on the server.

Parent topic:OTA Upgrade events

Client-side Events

- **E_CLD_OTA_COMMAND_IMAGE_NOTIFY**
  - This event is generated on the client when an Image Notify message is received from the server to indicate that a new application image is available for download. If the client decides to download the image, the application should react to

this event by sending a Query Next Image Request to the server using the function **eOTA_ClientQueryNextImageRequest()**.

- **E_CLD_OTA_COMMAND_QUERY_NEXT_IMAGE_RESPONSE**
  - This event is generated on the client when a Query Next Image Response is received from the server (in response to a Query Next Image Request) to indicate whether a new application image is available for download. If a suitable image is reported, the client initiates a download by sending an Image Block Request to the server.
- **E_CLD_OTA_COMMAND_BLOCK_RESPONSE**
  - This event is generated on the client when an Image Block Response is received from the server (in response to an Image Block Request) and contains a block of image data which is part of a download. Following this event, the client can request the next block of image data by sending an Image Block Request to the server or, if the entire image has been received and verified, the client can close the download by sending an Upgrade End Request to the server.
- **E_CLD_OTA_COMMAND_UPGRADE_END_RESPONSE**
  - This event is generated on the client when an Upgrade End Response is received from the server (in response to an Upgrade End Request) to confirm the end of a download. This event contains the time delay before the upgrade of the running application must be performed.
- **E_CLD_OTA_COMMAND_QUERY_SPECIFIC_FILE_RESPONSE**
  - This event is generated on the client when a Query Specific File Response is received from the server (in response to a Query Specific File Request) to indicate whether the requested application image is available for download.
- **E_CLD_OTA_INTERNAL_COMMAND_TIMER_EXPIRED**
  - This event is generated on the client when the local one-second timer has expired. It is an internal event and is not passed to the application.
- **E_CLD_OTA_INTERNAL_COMMAND_POLL_REQUIRED**
  - This event is generated on the client to prompt the application to poll the server for a new application image by calling the function **eOTA_ClientQueryNextImageRequest()**.
- **E_CLD_OTA_INTERNAL_COMMAND_RESET_TO_UPGRADE**
  - This event is generated on the client to notify the application that the stack is going to reset the device. No specific action is required by the application.
- **E_CLD_OTA_INTERNAL_COMMAND_SAVE_CONTEXT**
  - This event prompts the client application to store context data in Flash memory. The data to be stored is passed to the application within this event.
- **E_CLD_OTA_INTERNAL_COMMAND_OTA_DL_ABORTED**
  - This event is generated on a client if the received image is invalid or the client has aborted the image download. This allows the application to request the new image again.
- **E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_BLOCK_RESPONSE**
  - This event is generated on the client when an Image Block Response is received from the server in response to an Image Block Request for a device-specific file. The event contains a block of file data which is part of a download. Following this event, the client stores the data block in an appropriate location and can request the next block of file data by sending an Image Block Request to the server (if the complete image has not yet been received and verified).
- **E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_DL_COMPLETE**

  - This event is generated on the client when the final Image Block Response of a device-specific file download has been received from the server - the event indicates that all the data blocks that make up the file have been received.

- **E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_USE_NEW_FILE**
  - This event is generated on the client following a device-specific file download to indicate that the file can now be used by the client. At the end of the download, the server sends an Upgrade End Response that may include an 'upgrade time' - this is the UTC time at which the new file can be applied. Thus, on receiving this response, the client starts a timer and, on reaching the upgrade time, generates this event.
- **E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_DL_ABORT**
  - This event is generated to indicate that the OTA Upgrade cluster needs to abort a device-specific file download. Following this event, the application should discard data that has already been received as part of the aborted download.
- **E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_NO_UPGRADE_**

  END_RESPONSE
  - This event is generated when no Upgrade End Response has been received for a device-specific file download. The client makes three attempts to obtain an Upgrade End Response. If no response is received, the client raises this event.

Note: For a device-specific file download, it is not mandatory for the server to send an Upgrade End Response. The decision of whether to send the Upgrade End Response is manufacturer-specific.

- **E_CLD_OTA_COMMAND_QUERY_NEXT_IMAGE_RESPONSE_ERROR**
  - This event is generated on the client when a Query Next Image Response message is received from the server, in response to a Query Next Image Request with a status of Invalid Image Size.
- **E_CLD_OTA_INTERNAL_COMMAND_RCVD_DEFAULT_RESPONSE**
  - This event is generated on the client when a default response message is received from the server, in response to a Query Next Image Request, Image Block Request or Upgrade End Request. This is an internal ZCL event that results in an OTA download being aborted, thus activating the callback function for the E_CLD_OTA_INTERNAL_COMMAND_OTA_DL_ABORTED event.
- **E_CLD_OTA_INTERNAL_COMMAND_VERIFY_IMAGE_VERSION**
  - This event is generated to prompt the application to verify the image version received in a Query Next Image Response. This event allows the application to verify that the new upgrade image has a valid image version. After checking the image version, the application should set the status field of the event to E_ZCL_SUCCESS (valid version) or E_ZCL_FAIL (invalid version).
- **E_CLD_OTA_INTERNAL_COMMAND_SWITCH_TO_UPGRADE_**

  DOWNGRADE
  - This event is generated to prompt the application to verify the image version received in an upgrade end response. This event allows the application to verify that the new upgrade image has a valid image version.
  - After checking the image version, the application should set the status field of the event to E_ZCL_SUCCESS (valid version) or E_ZCL_FAIL (invalid version).
- **E_CLD_OTA_INTERNAL_COMMAND_FAILED_VALIDATING_UPGRADE_**

  IMAGE
  - This event is generated on the client when the validation of a new upgrade image fails. This validation takes place when the upgrade time is reached.

- **E_CLD_OTA_INTERNAL_COMMAND_FAILED_COPYING_SERIALIZATION_DATA**
  - This event is generated on the client when the copying of serialisation data from the active image to the new upgrade image fails. This process takes place after image validation (if applicable) is completed successfully.
- **E_CLD_OTA_BLOCK_RESPONSE_TAG_OTHER_THAN_UPGRADE_**

  IMAGE
  - This event is generated on the client when an Image Block Response is received from the server but the response contains a block of data that is not upgrade image data (it may contain tags such as an integrity code or ECDA signature).Thus, this event can help the application to process tags or data other than upgrade image data.

Parent topic:OTA Upgrade events

Server-side and Client-side Events

- **E_CLD_OTA_INTERNAL_COMMAND_LOCK_FLASH_MUTEX**
  - This event prompts the application to lock the mutex used for accesses to external Flash memory (via the SPI bus).
- **E_CLD_OTA_INTERNAL_COMMAND_FREE_FLASH_MUTEX**
  - This event prompts the application to unlock the mutex used for accesses to external Flash memory (via the SPI bus).

Parent topic:OTA Upgrade events

Parent topic:*OTA Upgrade cluster*

Functions The OTA Upgrade cluster functions that are provided in the NXP implementation of the ZCL are divided into the following three categories:

- General functions (used on server and client) - see Section 49.10.1
- Server functions - see Section 49.10.2
- Client functions - see Section 49.10.3

General Functions The following OTA Upgrade cluster functions can be used on the cluster server and the cluster client:

1. eOTA_Create
2. vOTA_FlashInit
3. eOTA_AllocateEndpointOTASpace
4. vOTA_GenerateHash
5. eOTA_GetCurrentOtaHeader

eOTA_Create

```
teZCL_Status eOTA_Create(
    tsZCL_ClusterInstance *psClusterInstance,
    bool_t bIsServer,
    tsZCL_ClusterDefinition *psClusterDefinition,
    void *pvEndPointSharedStructPtr,
    uint8 u8Endpoint,
    uint8 *pu8AttributeControlBits,
```

(continues on next page)

(continued from previous page)

```
tsOTA_Common *psCustomDataStruct);
```

Description This function creates an instance of the OTA Upgrade cluster on the specified endpoint. The cluster instance can act as a server or a client, as specified. The shared structure of the device associated with cluster must also be specified.

The function must be the first OTA function called in the application, and must be called after the stack has been started and after the ZCL has been initialized.

Parameters

- *psClusterInstance*: Pointer to structure containing information about the cluster instance to be created (see Section 6.1.16)
- *bIsServer*: Side of cluster to be implemented on this device:
  - TRUE - Server
  - FALSE - Client
- *psClusterDefinition*: Pointer to structure indicating the type of cluster (see Section 6.1.2) - this structure must contain the details of the OTA Upgrade cluster
- *pvEndPointSharedStructPtr*: Pointer to shared device structure for relevant endpoint (depends on device type, e.g. Door Lock)
- *u8Endpoint*: Number of endpoint with which cluster will be associated
- *pu8AttributeControlBits*: Pointer to an array of bitmaps, one for each attribute in the relevant cluster - for internal cluster definition use only, array should be initialised to 0
- *tpsCustomDataStruct*: Pointer to structure containing custom data for OTA Upgrade cluster (see Section 49.11.2)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: General Functions

vOTA_FlashInit

```
void vOTA_FlashInit(void *pvFlashTable,
    tsNvmDefs *psNvmStruct);
```

Description This function initializes the Flash memory device to be used by the OTA Upgrade cluster. Information about the device must be provided, such as the device type and sector size.

If a custom or unsupported Flash memory device is used then user-defined callback functions must be provided to perform Flash memory read, write, erase and initialization operations (if an NXP-supported device is used, standard callback functions will be used):

- A general set of functions (for use by all software components) can be specified through *pvFlashTable*.

- Optionally, an additional set of functions specifically for use by the OTA Upgrade cluster can be specified in the structure referenced by *psNvmStruct*.

This function must be called after the OTA Upgrade cluster has been created (after **eOTA_Create()** has been called either directly or indirectly) and before any other OTA Upgrade functions are called.

Parameters

- *pvFlashTable*: Pointer to general set of callback functions to perform Flash memory read, write, erase and initialization operations. If using an NXP-supported Flash memory device, set a null pointer to use standard callback functions
- *psNvmStruct*: Pointer to structure containing information on Flash memory device - see Section 49.11.4

Returns

- None

Parent topic: General Functions

eOTA_AllocateEndpointOTASpace

```
teZCL_Status eOTA_AllocateEndpointOTASpace(
    uint8 u8Endpoint,
    uint8 *pu8Data,
    uint8 u8NumberOfImages,
    uint8 u8MaxSectorsPerImage,
    bool_t bIsServer,
    uint8 *pu8CAPublicKey);
```

Description This function is used to allocate Flash memory space to store application images as part of the OTA upgrade process for the specified endpoint. The maximum number of images that are held at any one time must be specified as well the Flash memory start sector of every image. The maximum number of sectors used to store an image must also be specified.

The start sectors of the image space allocations are provided in an array. The index of an element of this array will subsequently be used to identify the stored image in other function calls.

Advice about the allocation of internal Flash memory space to OTA upgrade images on the client is provided in Appendix E.2

Parameters

- *u8Endpoint*: Number of endpoint for which Flash memory space is to be allocated
- *pu8Data*: Pointer to array containing the Flash memory start sector of each image (array index identifies image)
- *u8NumberOfImages*: Maximum number of application images that are stored in Flash memory at any one time
- *u8MaxSectorsPerImage*: Maximum number of sectors to be used to store an individual application image
- *bIsServer*: Side of cluster implemented on this device:
- TRUE - Server

- FALSE - Client
- *pu8CAPublicKey*: Pointer to Certificate Authority public key (provided in the security certificate from a company such as Certicom)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL
- E_ZCL_ERR_INVALID_VALUE
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_PARAMETER_NULL

Parent topic: General Functions

vOTA_GenerateHash

```
void vOTA_GenerateHash(
    tsZCL_EndPointDefinition *psEndPointDefinition,
    tsOTA_Common *psCustomData,
    bool bIsServer,
    bool bHeaderPresent,
    AESSW_Block_u *puHash,
    uint8 u8ImageLocation);
```

Description This function can be used to generate a hash checksum for an application image in Flash memory, using the Matyas-Meyer-Oseas cryptographic hash.

Parameters

- *psEndPointDefinition* Pointer to structure which defines endpoint corresponding to the application (see Section 6.1.1)
- *psCustomData* Pointer to data structure connected with event associated with the checksum (see Section 49.11.2)
- *bIsServer* Side of cluster implemented on this device:
- TRUE - Server
- FALSE - Client
- *bHeaderPresent* Presence of image header:
- TRUE - Present
- FALSE - Absent
- *puHash* Pointer to structure to receive calculated hash checksum
- *u8ImageLocation* Number of sector where image starts in Flash memory

Returns

- None

Parent topic: General Functions

eOTA_GetCurrentOtaHeader

```
teZCL_Status eOTA_GetCurrentOtaHeader(
    uint8 u8Endpoint,
    bool_t bIsServer,
    tsOTA_ImageHeader *psOTAHeader);
```

Description This function can be used to obtain the OTA header of the application image which is currently running on the local node.

The obtained parameter values are received in a tsOTA_ImageHeader structure.

Parameters

- *u8Endpoint* Number of endpoint on which cluster operates
- *bIsServer* Side of the cluster implemented on this device:
- TRUE - Server
- FALSE - Client
- *psOTAHeader* Pointer to structure to receive the current OTA header (see Section 49.11.1)

Returns

- E_ZCL_SUCCESS
- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_ERR_PARAMETER_NULL

Parent topic: General Functions

Parent topic: Functions

Server Functions The following OTA Upgrade cluster functions can be used on the cluster server only:

1. eOTA_SetServerAuthorisation
2. eOTA_SetServerParams
3. eOTA_GetServerData
4. eOTA_EraseFlashSectorsForNewImage
5. eOTA_FlashWriteNewImageBlock
6. eOTA_NewImageLoaded
7. eOTA_ServerImageNotify
8. eOTA_ServerQueryNextImageResponse
9. eOTA_ServerImageBlockResponse
10. eOTA_SetWaitForDataParams
11. eOTA_ServerUpgradeEndResponse
12. eOTA_ServerSwitchToNewImage

13. eOTA_InvalidateStoredImage
14. eOTA_ServerQuerySpecificFileResponse

eOTA_SetServerAuthorisation

```
teZCL_Status eOTA_SetServerAuthorisation(
    uint8 u8Endpoint,
    eOTA_AuthorisationState eState,
    uint64 *pu64WhiteList,
    uint8 u8Size);
```

Description This function can be used to define a set of clients to which the server is authorized to download application images. The function allows all clients to be authorized or a list of selected authorized clients to be provided. Clients are specified in this list by means of their 64-bit IEEE/MAC addresses.

Parameters

- *u8Endpoint*: Number of endpoint (on server) on which cluster operates
- *eState*: Indicates whether a list of authorized clients is used or all clients are authorized - one of:
  - E_CLD_OTA_STATE_USE_LIST
  - E_CLD_OTA_STATE_ALLOW_ALL
- *pu64WhiteList*: Pointer to list of IEEE/MAC addresses of authorized clients (ignored if all clients are authorized through *eState* parameter)
- *u8Size* Number of clients in list
- (ignored if all clients are authorized through *eState* parameter)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Server Functions

eOTA_SetServerParams

```
teZCL_Status eOTA_SetServerParams(
    uint8 u8Endpoint,
    uint8 u8ImageIndex,
    tsCLD_PR_Ota *psOTAData);
```

Description This function can be used to set server parameter values (including query jitter, data size, image data, current time and upgrade time) for a particular image stored on the server. The parameter values to be set are specified in a structure, described in Section 49.11.22. For detailed descriptions of these parameters, refer to the *ZigBee Over-the-Air Upgrading Cluster Specification (095264)*from the ZigBee Alliance.

If this function is not called, default values are used for these parameters.

The current values of these parameters can be obtained using the function **eOTA_GetServerData()**.

The index of the image for which server parameter values are to be set must be specified. For an image stored in Flash memory, this index will take a value in the range 0 to (OTA_MAX_IMAGES_PER_ENDPOINT - 1).

Parameters

- *u8Endpoint*: Number of endpoint (on server) on which cluster operates
- *u8ImageIndex*: Index number of image
- *psOTAData*: Pointer to structure containing parameter values to be set (see Section 49.11.22)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Server Functions

eOTA_GetServerData

```
teZCL_Status eOTA_GetServerData(
    uint8 u8Endpoint,
    uint8 u8ImageIndex,
    tsCLD_PR_Ota *psOTAData);
```

Description This function can be used to obtain server parameter values (including query jitter, data size, image data, current time and upgrade time). The obtained parameter values are received in a structure, described in Section 49.11.22. For detailed descriptions of these parameters, refer to the *ZigBee Over-the-Air Upgrading Cluster Specification (095264)*from the ZigBee Alliance.

The values of these parameters can be set by the application using the function **eOTA_SetServerParams()**.

The index of the image for which server parameter values are to be obtained must be specified. For an image stored in the Flash memory, this index will take a value in the range 0 to (OTA_MAX_IMAGES_PER_ENDPOINT - 1).

Parameters

- *u8Endpoint*: Number of endpoint (on server) on which cluster operates
- *u8ImageIndex*: Index number of image
- *psOTAData*: Pointer to structure to receive parameter values (see Section 49.11.22)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Server Functions

eOTA_EraseFlashSectorsForNewImage

```
teZCL_Status eOTA_EraseFlashSectorsForNewImage(
    uint8 u8Endpoint,
    uint8 u8ImageIndex);
```

Description This function can be used to erase certain sectors of the Flash memory of the device in the OTA server node. The sectors allocated to the specified image index number will be erased so that the sectors (and index number) can be re-used. The function is normally called before writing a new upgrade image to Flash memory.

The specified image index number must be in the range 0 to (OTA_MAX_IMAGES_PER_ENDPOINT - 1).

Parameters

- *u8Endpoint*: Number of endpoint (on server) on which cluster operates
- *u8ImageIndex*: Index number of image

Returns

- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_SUCCESS

Parent topic: Server Functions

eOTA_FlashWriteNewImageBlock

```
teZCL_Status eOTA_FlashWriteNewImageBlock(
    uint8 u8Endpoint,
    uint8 u8ImageIndex,
    bool bIsServerImage,
    uint8 *pu8UpgradeBlockData,
    uint8 u8UpgradeBlockDataLength,
    uint32 u32FileOffSet);
```

Description This function can be used to write a block of an upgrade image to the devices internal Flash memory in the OTA server node. The image may be either of the following:

- An upgrade image for the server itself (the server will later be rebooted from this image)
- An upgrade image for one or more clients, which will later be made available for OTA distribution through the wireless network

The image in Flash memory to which the block belongs is identified by its index number. The specified image index number must be in the range 0 to (OTA_MAX_IMAGES_PER_ENDPOINT - 1).

Note that for JN518x, K32W041, and K32W061, internal Flash memory, writes must be 512-byte aligned.

Parameters

- *u8Endpoint*: Number of endpoint (on server) on which cluster operates
- *u8ImageIndex*: Index number of image
- *bIsServerImage*: Indicates whether new image is for the server or a client:
- TRUE - Server image
- FALSE - Client image
- *pu8UpgradeBlockData*: Pointer to image block to be written
- *u8UpgradeBlockDataLength*: Size, in bytes, of image block to be written
- *u32FileOffSet*: Offset of block from start of image file (in terms of number of bytes)

Returns

- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_FAIL
- E_ZCL_SUCCESS

Parent topic: Server Functions

eOTA_NewImageLoaded

```
teZCL_Status eOTA_NewImageLoaded(
        uint8 u8Endpoint,
        bool bIsImageOnCoProcessorMedia,
        tsOTA_CoProcessorOTAHeader
    *psOTA_CoProcessorOTAHeader);
```

Description This function can be used for two purposes which relate to a new application image and which depend on whether the image has been stored in the internal Flash memory of the device or in the external storage device of a co-processor (if any) within the server node:

- For an image stored in internal Flash memory, the function can be used to notify the OTA Upgrade cluster server on the specified endpoint that a new application image has been loaded into Flash memory and is available for download to clients. The server then validates the new image.
- For one or more images stored in the co-processor's external storage device, the function can be used to provide OTA header information for the image(s) to the cluster server. In the case of more than one image stored in co-processor storage, this function may replicate OTA header information for older images already registered with the server.

Note: The co-processor option is currently not supported for JN518x, K32W041, or K32W061.

Parameters

- *u8Endpoint*: Number of endpoint (on server) on which cluster operates
- *bIsImageOnCoProcessorMedia*: Flag indicating whether image is stored in co-processor external storage device:
- TRUE - Stored in co-processor

- FALSE - Stored in internal Flash memory
- *psOTA_CoProcessorOTAHeader*: Pointer to OTA headers of images which are held in co-processor storage device

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Server Functions

eOTA_ServerImageNotify

```
teZCL_Status eOTA_ServerImageNotify(
    uint8 u8SourceEndpoint,
    uint8 u8DestinationEndpoint,
    tsZCL_Address *psDestinationAddress,
    tsOTA_ImageNotifyCommand *psImageNotifyCommand);
```

Description This function issues an Image Notify message to one or more clients to indicate that a new application image is available for download.

The message can be unicast to an individual client or multicast to selected clients (but cannot be broadcast to all clients, for security reasons).

Parameters

- *u8SourceEndpoint*: Number of endpoint (on server) from which the message is sent
- *u8DestinationEndpoint*: Number of endpoint (on client) to which the message is sent
- *psDestinationAddress*: Pointer to structure containing the address of the target client for the message - a multicast to more than one client is also possible (see Section 6.1.4)
- *psImageNotifyCommand*: Pointer to structure containing payload for message (see Section 49.11.5)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Server Functions

eOTA_ServerQueryNextImageResponse

```
teZCL_Status eOTA_ServerQueryNextImageResponse(
        uint8 u8SourceEndpoint,
    uint8 u8DestinationEndpoint,
    tsZCL_Address *psDestinationAddress,
    tsOTA_QueryImageResponse
    *psQueryImageResponsePayload,
    uint8 u8TransactionSequenceNumber);
```

Description This function issues a Query Next Image Response to a client which has sent a Query Next Image Request (the arrival of this request triggers the event E_CLD_OTA_COMMAND_QUERY_NEXT_IMAGE_REQUEST on the server).

The Query Next Image Response contains information on the latest application image available for download to the client, including the image size and file version.

Note: The cluster server responds automatically to a Query Next Image Request, so it is not normally necessary for the application to call this function.

You are also required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndpoint*: Number of endpoint (on server) from which the response is sent
- *u8DestinationEndpoint*: Number of endpoint (on client) to which the response is sent
- *psDestinationAddress*: Pointer to structure containing the address of the target client for the response (see Section 6.1.4)
- *psQueryImageResponsePayload*: Pointer to structure containing payload for response (see Section 49.11.7)
- *u8TransactionSequenceNumber*: Pointer to a location to store the Transaction Sequence Number (TSN) of the request

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Server Functions

eOTA_ServerImageBlockResponse

```
teZCL_Status eOTA_ServerImageBlockResponse(
    uint8 u8SourceEndpoint,
    uint8 u8DestinationEndpoint,
    tsZCL_Address *psDestinationAddress,
    tsOTA_ImageBlockResponsePayload
    *psImageBlockResponsePayload,
    uint8 u8BlockSize,
    uint8 u8TransactionSequenceNumber);
```

Description This function issues an Image Block Response, containing a block of image data, to a client to which the server is downloading an application image. The function is called after receiving an Image Block Request from the client, indicating that the client is ready to receive the next block of the application image (the arrival of this request triggers the event E_CLD_OTA_COMMAND_BLOCK_REQUEST on the server).

The size of the block, in bytes, is specified as part of the function call. This must be less than or equal to the maximum possible block size defined in the **zcl_options.h** file (see Section 49.13).

Note: The cluster server responds automatically to an Image Block Request, so it is not normally necessary for the application to call this function.

You are also required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndpoint*: Number of endpoint (on server) from which the response is sent
- *u8DestinationEndpoint*: Number of endpoint (on client) to which the response is sent
- *psDestinationAddress*: Pointer to structure containing the address of the target client for the response (see Section 6.1.4)
- *psImageBlockResponsePayload*: Pointer to structure containing payload for response (see Section 49.11.10)
- *u8BlockSize*: Size, in bytes, of block to be transferred
- *u8TransactionSequenceNumber*: Pointer to a location to store the Transaction Sequence Number (TSN) of the request

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Server Functions

eOTA_SetWaitForDataParams

```
teZCL_Status eOTA_SetWaitForDataParams(
    uint8 u8Endpoint,
    uint16 u16ClientAddress,
    tsOTA_WaitForData *sWaitForDataParams);
```

Description This function can be used to send an Image Block Response with a status of OTA_STATUS_WAIT_FOR_DATA to a client, in response to an Image Block Request from the client.

The payload of this response includes a new value for the 'block request delay' attribute on the client. This value can be used by the client for 'rate limiting' -that is, to control the rate at which the client requests data blocks from the server and therefore the average OTA download rate from the server to the client.

Rate limiting is described in more detail in Section 49.8.1.

Parameters

- *u8Endpoint*: Number of endpoint (on server) from which the response is sent
- *u16ClientAddress*: Network address of client device to which the response is sent
- *sWaitForDataParams*: Pointer to structure containing 'Wait for Data' parameter values for Image Block Response payload (see Section49.11.15)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Server Functions

eOTA_ServerUpgradeEndResponse

```
teZCL_Status eOTA_ServerUpgradeEndResponse(
    uint8 u8SourceEndpoint,
    uint8 u8DestinationEndpoint,
    tsZCL_Address *psDestinationAddress,
    tsOTA_UpgradeEndResponsePayload
    *psUpgradeResponsePayload,
    uint8 u8TransactionSequenceNumber);
```

Description This function issues an Upgrade End Response to a client to which the server has been downloading an application image. The function is called after receiving an Upgrade End Request from the client, indicating that the client has received the entire application image and verified it (the arrival of this request triggers the event E_CLD_OTA_COMMAND_UPGRADE_END_REQUEST on the server).

The Upgrade End Response includes the upgrade time for the downloaded image as well as the current time (the client will use this information to implement a delay before upgrading the running application image).

Note: The cluster server responds automatically to an Upgrade End Request, so it is not normally necessary for the application to call this function.

You are also required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndpoint*: Number of endpoint (on server) from which the response is sent
- *u8DestinationEndpoint*: Number of endpoint (on client) to which the response is sent
- *psDestinationAddress*: Pointer to structure containing the address of the target client for the response (see Section 6.1.4)
- *psUpgradeResponsePayload*: Pointer to structure containing payload for response (see Section 49.11.12)
- *u8TransactionSequenceNumber*: Pointer to a location to store the Transaction Sequence Number (TSN) of the request

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Server Functions

eOTA_ServerSwitchToNewImage

```
teZCL_Status eOTA_ServerSwitchToNewImage(
    uint8 u8Endpoint,
    uint8 u8ImageIndex);
```

Description This function can be used to force a reset of the device in the OTA server node and, on reboot, run a new application image that has been saved in the attached Flash memory.

Before forcing the reset of the remove device, the function checks whether the version of the new image is greater than the version of the current image. If this is the case, the function invalidates the currently running image in Flash memory and initiates a software reset - otherwise, it returns an error.

The new application image is identified by its index number. The specified image index number must be in the range 0 to (OTA_MAX_IMAGES_PER_ENDPOINT - 1).

Parameters

- *u8Endpoint*: Number of endpoint (on server) on which cluster operates
- *u8ImageIndex*: Index number of image

Returns

- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_FAIL
- E_ZCL_SUCCESS

Parent topic: Server Functions

eOTA_InvalidateStoredImage

```
teZCL_Status eOTA_InvalidateStoredImage(
    uint8 u8Endpoint,
    uint8 u8ImageIndex);
```

Description This function can be used to invalidate an application image that is held in the Flash memory of the device. Once the image has been invalidated, it will no longer to available for OTA upgrade.

The image to be invalidated is identified by its index number. The specified image index number must be in the range 0 to (OTA_MAX_IMAGES_PER_ENDPOINT - 1).

Parameters

- *u8Endpoint*: Number of endpoint (on server) on which cluster operates
- *u8ImageIndex*: Index number of image to be invalidated

Returns

- E_ZCL_ERR_EP_RANGE
- E_ZCL_ERR_PARAMETER_NULL
- E_ZCL_ERR_CLUSTER_NOT_FOUND
- E_ZCL_SUCCESS

Parent topic: Server Functions

eOTA_ServerQuerySpecificFileResponse

```
teZCL_Status eOTA_ServerQuerySpecificFileResponse(
    uint8 u8SourceEndpoint,
    uint8 u8DestinationEndpoint,
    tsZCL_Address *psDestinationAddress,
    tsOTA_QuerySpecificFileResponsePayload
    *psQuerySpecificFileResponsePayload,
    uint8 u8TransactionSequenceNumber);
```

Description This function can be used to issue a Query Specific File Response to a client which has sent a Query Specific File Request (the arrival of this request triggers the event E_CLD_OTA_COMMAND_QUERY_SPECIFIC_FILE_REQUEST on the server). The Query Specific File Response contains information on the latest device-specific file available for download to the client, including the file size and file version.

You are also required to provide a pointer to a location to receive a Transaction Sequence Number (TSN) for the request. The TSN in the response is set to match the TSN in the request, allowing an incoming response to be paired with a request. This is useful when sending more than one request to the same destination endpoint.

Parameters

- *u8SourceEndpoint*: Number of endpoint (on server) from which the response is sent
- *u8DestinationEndpoint*: Number of endpoint (on client) to which the response is sent
- *psDestinationAddress*: Pointer to structure containing the address of the target client
- *psQuerySpecificFileResponsePayload*:
- Pointer to structure containing payload for Query Specific File Response (see Section 49.11.20)
- *u8TransactionSequenceNumber*: Pointer to a location to store the Transaction Sequence Number (TSN) of the request

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Server Functions

Parent topic: Functions

Client Functions The following OTA Upgrade cluster functions can be used on the cluster client only:

1. eOTA_SetServerAddress
2. eOTA_ClientQueryNextImageRequest
3. eOTA_ClientImageBlockRequest
4. eOTA_ClientImagePageRequest
5. eOTA_ClientUpgradeEndRequest
6. eOTA_HandleImageVerification
7. eOTA_UpdateClientAttributes
8. eOTA_RestoreClientData
9. vOTA_SetImageValidityFlag
10. eOTA_ClientQuerySpecificFileRequest
11. eOTA_SpecificFileUpgradeEndRequest
12. vOTA_SetLowVoltageFlag

eOTA_SetServerAddress

```
teZCL_Status eOTA_SetServerAddress(
    uint8 u8Endpoint,
    uint64 u64IeeeAddress,
    uint16 u16ShortAddress);
```

Description This function sets the addresses (64-bit IEEE/MAC address and 16-bit network address) of the OTA Upgrade cluster server that will be used to provide application upgrade images to the local client.

The function should be called after a server discovery has been performed to find a suitable server - this is done by sending out a Match Descriptor Request using the function **ZPS_eAplZdpMatchDescRequest()** described in the*ZigBee 3.0 Stack User Guide (JNUG3130)*. The server discovery must be completed and a server address set before any OTA-related message exchanges can occur (e.g. image request).

Parameters

- *u8Endpoint*: Number of endpoint corresponding to application
- *u64IeeeAddress*: IEEE/MAC address of server
- *u16ShortAddress*: Network address of server

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Client Functions

eOTA_ClientQueryNextImageRequest

```
teZCL_Status eOTA_ClientQueryNextImageRequest(
    uint8 u8SourceEndpoint,
    uint8 u8DestinationEndpoint,
    tsZCL_Address *psDestinationAddress,
    tsOTA_QueryImageRequest
*psQueryImageRequest);
```

Description This function issues a Query Next Image Request to the server and should be called in either of the following situations:

- to poll for a new application image (typically used in this way by an End Device) - in this case, the function should normally be called periodically
- to respond to an Image Notify message from the server, which indicated that a new application image is available for download - in this case, the function call should be prompted by the event E_CLD_OTA_COMMAND_IMAGE_NOTIFY

The payload of the request includes the relevant image type, current file version, hardware version and manufacturer code.

As a result of this function call, a Query Next Image Response will (eventually) be received from the server. The arrival of this response will trigger an E_CLD_OTA_COMMAND_QUERY_NEXT_IMAGE_RESPONSE event.

Parameters

- *u8SourceEndpoint*: Number of endpoint (on client) from which the request is sent
- *u8DestinationEndpoint*: Number of endpoint (on server) to which the request is sent
- *psDestinationAddress*: Pointer to structure containing the address of the target server (see Section 6.1.4)
- *psQueryImageRequest*: Pointer to structure containing payload for request (see Section 49.11.6)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Client Functions

eOTA_ClientImageBlockRequest

```
teZCL_Status eOTA_ClientImageBlockRequest(
        uint8 u8SourceEndpoint,
        uint8 u8DestinationEndpoint,
        tsZCL_Address *psDestinationAddress,
        tsOTA_BlockRequest
    *psOtaBlockRequest);
```

Description This function can be used during an image download to send an Image Block Request to the server, in order to request the next block of image data.

As a result of this function call, an Image Block Response containing the requested data block will (eventually) be received from the server. The arrival of this response will trigger an E_CLD_OTA_COMMAND_QUERY_NEXT_IMAGE_RESPONSE event.

Note: The cluster client automatically sends Image Block Requests to the server during a download, so it is not normally necessary for the application to call this function.

Parameters

- *u8SourceEndpoint*: Number of endpoint (on client) from which the request is sent
- *u8DestinationEndpoint*: Number of endpoint (on server) to which the request is sent
- *psDestinationAddress*: Pointer to structure containing the address of the target server (see Section 6.1.4)
- *psOtaBlockRequest*: Pointer to structure containing payload for request (see Section 49.11.8)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Client Functions

eOTA_ClientImagePageRequest

```
teZCL_Status eOTA_ClientImagePageRequest(
    uint8 u8SourceEndpoint,
    uint8 u8DestinationEndpoint,
    tsZCL_Address *psDestinationAddress,
    tsOTA_ImagePageRequest *psOtaPageRequest);
```

Description This function can be used during an image download to send an Image Page Request to the server, in order to request the next page of image data. In this function call, a structure must be supplied which contains the payload data for the request. This data includes the page size, in bytes.

Note 1: Image Page Requests can be used instead of Image Block Requests if page requests have been enabled in the **zcl_options.h** file for the client and server (see Section 49.13).

Note 2: The cluster client automatically sends Image Page Requests (if enabled) to the server during a download, so it is not normally necessary for the application to call this function.

As a result of this function call, a sequence of Image Block Responses containing the requested data will (eventually) be received from the server. The arrival of each response will trigger an E_CLD_OTA_COMMAND_BLOCK_RESPONSE event on the client. If this function is used (rather than the stack) to issue Image Page Requests, it is the responsibility of the application to keep a count of the number of data bytes received since the Image Page Request was issued - when all the requested page data has been received, this count will equal the specified page size.

Page requests are described in more detail in Section 49.8.4.

Parameters

- *u8SourceEndpoint*: Number of endpoint (on client) from which the request is sent
- *u8DestinationEndpoint*: Number of endpoint (on server) to which the request is sent

- *psDestinationAddress*: Pointer to structure containing the address of the target server (see Section 6.1.4)
- *psOtaPageRequest*: Pointer to structure containing payload for request (see Section 49.11.9)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Client Functions

eOTA_ClientUpgradeEndRequest

```
teZCL_Status eOTA_ClientUpgradeEndRequest(
    uint8 u8SourceEndpoint,
    uint8 u8DestinationEndpoint,
    tsZCL_Address *psDestinationAddress,
    tsOTA_UpgradeEndRequestPayload
    *psUpgradeEndRequestPayload);
```

Description This function can be used during an image download to send an Upgrade End Request to the server. This is normally used to indicate that all the image data has been received and that the image has been successfully verified - it is the responsibility of the client to determine when all the image data has been received (using the image size quoted in the original Query Next Image Response) and then to verify the image.

In addition to the status OTA_STATUS_SUCCESS described above, the function can be used by the client to report other conditions to the server:

- OTA_REQUIRE_MORE_IMAGE: The downloaded image was successfully received and verified, but the client requires multiple images before performing an upgrade
- OTA_STATUS_INVALID_IMAGE: The downloaded image failed the verification checks and will be discarded
- OTA_STATUS_ABORT The image download that is currently in progress should be cancelled

In all three of the above cases, the client may then request another download.

When the function is called to report success, an Upgrade End Response will (eventually) be received from the server, indicating when the image upgrade should be implemented (a time delay may be indicated in the response). The arrival of this response will trigger an E_CLD_OTA_COMMAND_UPGRADE_END_RESPONSE event.

Note: The cluster client automatically sends an Upgrade End Request to the server on completion of a download, so it is not normally necessary for the application to call this function.

Parameters

- *u8SourceEndpoint*: Number of endpoint (on client) from which the request is sent
- *u8DestinationEndpoint*: Number of endpoint (on server) to which the request is sent
- *psDestinationAddress*: Pointer to structure containing the address of the target server (see Section 6.1.4)
- *psUpgradeEndRequestPayload*: Pointer to structure containing payload for request, including reported status (see Section49.11.11)

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Client Functions

eOTA_HandleImageVerification

```
teZCL_Status eOTA_HandleImageVerification(
    uint8 u8SourceEndPointId,
    uint8 u8DstEndpoint,
    teZCL_Status eImageVerificationStatus);
```

Description This function transmits an upgrade end request with the specified status.

Parameters

- *u8SourceEndPointId*: Identifier of endpoint on which the cluster client operates
- *u8DstEndpoint*: Identifier of endpoint (on the server) to which the upgrade end request is sent
- *eImageVerificationStatus*: Image status code

Returns

- E_ZCL_FAIL
- E_ZCL_SUCCESS

Parent topic: Client Functions

eOTA_UpdateClientAttributes

```
teZCL_Status eOTA_UpdateClientAttributes(
    uint8 u8Endpoint);
```

Description This function can be used on a client to set the OTA Upgrade cluster attributes to their default values. It should be called during application initialization after the cluster instance has been created using **eOTA_Create()**.

Following subsequent resets, provided that context data has been saved, the application should call **eOTA_RestoreClientData()** instead of this function.

Parameters

- *u8Endpoint*: Number of endpoint corresponding to context data

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Client Functions

eOTA_RestoreClientData

```
teZCL_Status eOTA_RestoreClientData(
    uint8 u8Endpoint,
    tsOTA_PersistedData *psOTAData,
    bool_t bReset);
```

Description This function can be used to restore OTA Upgrade context data that has been previously saved to Flash memory (using the NVM) on the local client - for example, it restores the OTA Upgrade attribute values. The function can be used to restore the data in RAM following a device reset or simply to refresh the data in RAM.

Parameters

- *8Endpoint*: Number of endpoint corresponding to context data
- *psOTAData*: Pointer to structure containing the context data to be restored (see Section 49.11.13)
- *bReset*: Indicates whether the data restoration follows a reset:
- TRUE - Follows a reset
- FALSE - Does not follow a reset

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Client Functions

vOTA_SetImageValidityFlag

```
void vOTA_SetImageValidityFlag(
    uint8 u8Location,
    tsOTA_Common *psCustomData,
    bool bSet,
    tsZCL_EndPointDefinition *psEndPointDefinition);
```

Description This function can be used to set an image validity flag once a downloaded upgrade image has been received and verified by the client.

Parameters

- *u8Location*: Number of sector where image starts in Flash memory
- *psCustomData*: Pointer to custom data for image (see Section 49.11.2)
- *bSet*: Flag state to be set:
- TRUE - Reset
- FALSE - No reset
- *psEndPointDefinition*: Pointer to endpoint definition (see Section 6.1.1)

Returns

- None

Parent topic: Client Functions

eOTA_ClientQuerySpecificFileRequest

```
eOTA_ClientQuerySpecificFileRequest(
    uint8 u8SourceEndpoint,
    uint8 u8DestinationEndpoint,
    tsZCL_Address *psDestinationAddress,
    tsOTA_QuerySpecificFileRequestPayload
*psQuerySpecificFileRequestPayload);
```

Description This function can be used to issue a Query Specific File Request to the server. It should be called to request a device-specific file from the server. As a result of this function call, a Query Specific File Response will (eventually) be received in reply.

Parameters

- *u8SourceEndpoint*: Number of endpoint (on client) from which the request is sent
- *u8DestinationEndpoint*: Number of endpoint (on server) to which the request is sent
- *psDestinationAddress*: Pointer to structure containing the address of the target server
- *psQuerySpecificFileRequestPayload*: Pointer to structure containing payload for Query Specific File Request

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Client Functions

eOTA_SpecificFileUpgradeEndRequest

```
eOTA_SpecificFileUpgradeEndRequest(
    uint8 u8SourceEndPointId,
    uint8 u8Status);
```

Description This function can be used to issue an Upgrade End Request for the device-specific file download that is in progress in order to indicate to the server that the download has completed. This request can be issued by the client optionally after the downloaded image has been verified and found to be valid.

Parameters

- *u8SourceEndPointId*: Number of endpoint (on client) from which the request is sent
- *u8Status*: Download status of device-specific file - if the file has been completely and successfully received, this parameter must be set to OTA_STATUS_SUCCESS

Returns

- E_ZCL_SUCCESS
- E_ZCL_FAIL

Parent topic: Client Functions

vOTA_SetLowVoltageFlag

```
void vOTA_SetLowVoltageFlag(bool bValue);
```

Description This function can be used to configure the low-voltage flag on a node hosting an OTA Upgrade cluster client. This flag should be set when the supply voltage to the underlying hardware is below that required for normal operation and the node should not participate in an OTA upgrade.

- When the flag is set, the client stops sending Image Block Requests to the server
- When the flag is cleared, the client resumes sending Image Block Requests to the server

Use of the low-voltage flag must be enabled at compile-time by including the macro OTA_UPGRADE_VOLTAGE_CHECK in the **zcl_options.h** file.

Use of the low-voltage flag is described further in Section 49.8.7.

Parameters

- *bValue*: Determines the state of the low-voltage flag, as follows:
  - TRUE - Sets the flag
  - FALSE - Clears the flag

Returns

- None

Parent topic: Client Functions

Parent topic: Functions

Parent topic:*OTA Upgrade cluster*

Structures

tsOTA_ImageHeader The following structure contains information for the OTA header:

```
typedef struct
{
        uint32 u32FileIdentifier;
    uint16 u16HeaderVersion;
    uint16 u16HeaderLength;
    uint16 u16HeaderControlField;
    uint16 u16ManufacturerCode;
    uint16 u16ImageType;
    uint32 u32FileVersion;
    uint16 u16StackVersion;
    uint8  stHeaderString[OTA_HEADER_STRING_SIZE];
```

(continues on next page)

(continued from previous page)

```
        uint32 u32TotalImage;
    uint8  u8SecurityCredVersion;
    uint64 u64UpgradeFileDest;
    uint16 u16MinimumHwVersion;
    uint16 u16MaxHwVersion;
}tsOTA_ImageHeader;
```

where:

- u32FileIdentifier is a 4-byte value equal to 0x0BEEF11E which indicates that the file contains an OTA upgrade image
- u16HeaderVersion is the version of the OTA header expressed as a 2-byte value in which the most significant byte contains the major version number and the least significant byte contains the minor version number
- u16HeaderLength is the full length of the OTA header, in bytes
- u16HeaderControlField is a bitmap indicating certain information about the file, as detailed in table below.

Bit	Information
0	Security credential version (in OTA header):

1: Field present in header

0: Field not present in header

| |1|Device-specific file (also see u64UpgradeFileDest):

1: File is device-specific

0: File is not device-specific

| |2|Maximum and minimum hardware version (in OTA header):

1: Field present in header

0: Field not present in header

| |3-15|Reserved|

- u16ManufacturerCode is the ZigBee-assigned manufacturer code (0xFFFF is a wildcard value, representing any manufacturer)
- u16ImageType is a unique value representing the image type, where this value is normally manufacturer-specific but certain values have been reserved for specific file types, as indicated below (the wildcard value of 0xFFFF represents any file type):

Value	File Type
0x0000 – 0xFFBF	Manufacturer-specific
0xFFC0	Security credential
0xFFC1	Configuration
0xFFC2	Log
0xFFC3 – 0xFFFE	Reserved
0xFFFF	Wildcard

- u32FileVersion contains the release and build numbers of the application and stack used to produce the application image - for details of the file version format, refer to the *ZigBee Over-the-Air Upgrading Cluster Specification (095264)*

- u16StackVersion contains ZigBee stack version that is used by the application (this is 0x0002 for ZigBee PRO)
- stHeaderString[] is a manufacturer-specific string that can be used to store any useful human-readable information
- u32TotalImage is the total size, in bytes, of the image that will be transferred over-the air (including the OTA header and any optional data)
- u8SecurityCredVersion indicates the security credential version type that is required by the client in order to install the image - the possibilities are SE1.0 (0x0), SE1.1 (0x1) and SE2.0 (0x2)
- u64UpgradeFileDest contains the IEEE/MAC address of the destination device for the file, in the case when the file is device-specific (as indicated by bit 1 of u16HeaderControlField)
- u16MinimumHwVersion indicates the earliest hardware platform on which the image should be used, expressed as a 2-byte value in which the most significant byte contains the hardware version number and the least significant byte contains the revision number
- u16MaxHwVersion indicates the latest hardware platform on which the image should be used, expressed as a 2-byte value in which the most significant byte contains the hardware version number and the least significant byte contains the revision number

Parent topic: Structures

tsOTA_Common The following structure contains data relating to an OTA message received by the cluster (server or client) - this data is used for callback functions and the local OTA state machine:

```
typedef struct
{
    tsZCL_ReceiveEventAddress   sReceiveEventAddress;
    tsZCL_CallBackEvent         sOTACustomCallBackEvent;
    tsOTA_CallBackMessage       sOTACallBackMessage;
} tsOTA_Common;
```

The fields are for internal use and no knowledge of them is required. The tsOTA_CallBackMessage structure is described in Section 49.11.21.

Parent topic: Structures

tsOTA_HwFncTable The following structure contains pointers to callback functions to be used by the OTA Upgrade cluster to perform initialization, erase, write and read operations on Flash memory (if these functions are not specified, standard NXP functions will be used):

```
typedef struct
{
    void (*prInitHwCb)(uint8, void*);
    void (*prEraseCb) (uint8 u8Sector);
    void (*prWriteCb) (uint32 u32FlashByteLocation,
                       uint16 u16Len,
                       uint8 *pu8Data);
    void (*prReadCb)  (uint32 u32FlashByteLocation,
                       uint16 u16Len,
                       uint8 *pu8Data);
} tsOTA_HwFncTable;
```

where:

- prInitHwCb is a pointer to a callback function that is called after a cold or warm start to perform any initialization required for the Flash memory device
- prEraseCb is a pointer to a callback function that is called to erase a specified sector of Flash memory
- prWriteCb is a pointer to a callback function that is called to write a block of data to a sector, starting the write at a specified byte location in the sector (address zero is the start of the sector)
- prReadCb is a pointer to a callback function that is called to read a block of data from a sector, starting the read at a specified byte location in the sector (address zero is the start of the sector)

Parent topic: Structures

tsNvmDefs The following structure contains information used to configure access to Flash memory:

```
typedef struct
{
    tsOTA_HwFncTable sOtaFnTable;
    uint32           u32SectorSize;
    uint8            u8FlashDeviceType;
}tsNvmDefs;
```

where:

- sOtaFnTable is a structure specifying the callback functions to be used by the cluster to perform initialization, erase, write and read operations on the Flash memory device (see Section 49.11.3) - if user-defined callback functions are not specified, standard NXP functions will be used
- u32SectorSize is the size of a sector of the Flash memory device, in bytes
- u8FlashDeviceType is a value indicating the type of Flash memory device, one of:
  - E_FL_CHIP_INTERNAL (Device internal Flash- default)

Parent topic: Structures

tsOTA_ImageNotifyCommand The following structure contains the payload data for an Image Notify message issued by the server when a new upgrade image is available for download:

```
typedef struct
{
        teOTA_ImageNotifyPayloadType ePayloadType;
        uint32                       u32NewFileVersion;
        uint16                       u16ImageType;
        uint16                       u16ManufacturerCode;
        uint8                        u8QueryJitter;
}tsOTA_ImageNotifyCommand;
```

where:

- ePayloadType is a value indicating the type of payload of the command (enumerations are available - see Section 49.12.4)
- u32NewFileVersion is the file version of the client upgrade image that is currently available for download (the wild card of 0xFFFFFFFF is used to indicate that all clients should upgrade to this image)

- u16ImageType is a number indicating the type of image that is available for download (the wild card of 0xFFFF is used to indicate that all image types are involved)
- u16ManufacturerCode is a ZigBee-assigned number identifying the manufacturer to which the available image is connected (if all manufacturers are involved, this value should not be set)
- u8QueryJitter is a value between 1 and 100 (inclusive) which is used by the receiving client to decide whether to reply to this Image Notify message - for information on 'Query Jitter', refer to Section 49.7

Parent topic: Structures

tsOTA_QueryImageRequest The following structure contains payload data for a Query Next Image Request issued by a client to poll the server for an upgrade image or to respond to an Image Notify message from the server:

```
typedef struct
{
    uint32 u32CurrentFileVersion;
    uint16 u16HardwareVersion;
    uint16 u16ImageType;
    uint16 u16ManufacturerCode;
    uint8  u8FieldControl;
}tsOTA_QueryImageRequest;
```

where:

- u32CurrentFileVersion is the file version of the application image that is currently running on the client that sent the request
- u16HardwareVersion is the hardware version of the client device (this information is optional - see u8FieldControl below)
- u16ImageType is a value in the range 0x0000-0xFFBF which identifies the type of image currently running on the client
- u16ManufacturerCode is the ZigBee-assigned number identifying the manufacturer of the client device
- u8FieldControl is a bitmap indicating whether certain optional information about the client is included in this Query Next Image Request message. Currently, this optional information consists only of the hardware version (contained in u16HardwareVersion above) - bit 0 is set to '1' if the hardware version is included or to '0' otherwise (all other bits are reserved)

Parent topic: Structures

tsOTA_QueryImageResponse The following structure contains payload data for a Query Next Image Response issued by the server (as the result of a Query Next Image Request from a client):

```
typedef struct
{
    uint32 u32ImageSize;
    uint32 u32FileVersion;
    uint16 u16ManufacturerCode;
    uint16 u16ImageType;
    uint8  u8Status;
}tsOTA_QueryImageResponse;
```

where:

- u32ImageSize is the total size of the available image, in bytes
- u32FileVersion is the file version of the available image
- u16ManufacturerCode is the manufacturer code that was received from the client in the Query Next Image Request message
- u16ImageType is the image type that was received from the client in the Query Next Image Request message
- u8Status indicates whether a suitable image is available for download:
  - OTA_STATUS_SUCCESS: A suitable image is available
  - OTA_STATUS_NO_IMAGE_AVAILABLE: No suitable image is available
    * The other elements of the structure are only included in the case of success.

Parent topic: Structures

tsOTA_BlockRequest The following structure contains payload data for an Image Block Request issued by a client to request an image data block from the server:

```
typedef struct
{
    uint64 u64RequestNodeAddress;
    uint32 u32FileOffset;
    uint32 u32FileVersion;
    uint16 u16ImageType;
    uint16 u16ManufactureCode;
    uint16 u16BlockRequestDelay;
    uint8 u8MaxDataSize;
    uint8 u8FieldControl;
}tsOTA_BlockRequest;
```

where:

- u64RequestNodeAddress is the IEEE/MAC address of the client device from which the request originates (this information is optional - see u8FieldControl below)
- u32FileOffset specifies the offset from the beginning of the upgrade image, in bytes, of the requested data block (this value is therefore determined by the amount of image data previously received)
- u32FileVersion is the file version of the upgrade image for which a data block is being requested
- u16ImageType is a value in the range 0x0000-0xFFBF which identifies the type of image for which a data block is being requested
- u16ManufactureCode is the ZigBee-assigned number identifying the manufacturer of the client device from which the request originates
- u16BlockRequestDelay is used in 'rate limiting' to specify the value of the 'block request delay' attribute for the client - this is minimum time, in milliseconds, that the client must wait between consecutive block requests (the client will update the local attribute with this value). If the server does not support rate limiting or does not need to limit the download rate to the client, this field will be set to 0
- u8MaxDataSize specifies the maximum size, in bytes, of the data block that the client can receive in one transfer (the server must therefore not send a data block that is larger than indicated by this value)

- u8FieldControl is a bitmap indicating whether certain optional information about the client is included in this Image Block Request message. Currently, this optional information consists only of the IEEE/MAC address of the client (contained in 64RequestNodeAddress above) - bit 0 is set to '1' if this address is included or to '0' otherwise (all other bits are reserved)

Parent topic: Structures

tsOTA_ImagePageRequest The following structure contains payload data for an Image Page Request issued by a client to request a page of image data (multiple blocks) from the server:

```
typedef struct
{
    uint64 u64RequestNodeAddress;
    uint32 u32FileOffset;
    uint32 u32FileVersion;
    uint16 u16PageSize;
    uint16 u16ResponseSpacing;
    uint16 u16ImageType;
    uint16 u16ManufactureCode;
    uint8 u8MaxDataSize;
    uint8 u8FieldControl;
}tsOTA_ImagePageRequest;
```

where:

- u64RequestNodeAddress is the IEEE/MAC address of the client device from which the request originates (this information is optional - see u8FieldControl below)
- u32FileOffset specifies the offset from the beginning of the upgrade image, in bytes, of the first data block of the requested page (this value is therefore determined by the amount of image data previously received)
- u32FileVersion is the file version of the upgrade image for which data is being requested
- u16PageSize is the total number of data bytes (in the page) to be returned by the server before the next Image Page Request can be issued (this must be larger than the value of u8MaxDataSize below)
- u16ResponseSpacing specifies the time-interval, in milliseconds, that the server should introduce between consecutive transmissions of Image Block Responses (which is sent in response to the Image Page Request)
- u16ImageType is a value in the range 0x0000-0xFFBF which identifies the type of image for which data is being requested
- u16ManufactureCode is the ZigBee-assigned number identifying the manufacturer of the client device from which the request originates
- u8MaxDataSize specifies the maximum size, in bytes, of the data block that the client can receive in one transfer (the server must therefore not send a data block in an Image Block Response that is larger than indicated by this value)
- u8FieldControl is a bitmap indicating whether certain optional information about the client is included in this Image Page Request message. Currently, this optional information consists only of the IEEE/MAC address of the client (contained in 64RequestNodeAddress above) - bit 0 is set to '1' if this address is included or to '0' otherwise (all other bits are reserved)

Parent topic: Structures

tsOTA_ImageBlockResponsePayload The following structure contains payload data for an Image Block Response issued by the server (as the result of an Image Block Request from a client):

```
typedef struct
{
        uint8 u8Status;
        union
        {
                tsOTA_WaitForData                sWaitForData;
      tsOTA_SuccessBlockResponsePayload  sBlockPayloadSuccess;
        }uMessage;
}tsOTA_ImageBlockResponsePayload;
```

where:

- u8Status indicates whether a data block is included in the response:
  - OTA_STATUS_SUCCESS: A data block is included
  - OTA_STATUS_WAIT_FOR_DATA: No data block is included - client should re-request a data block after a waiting time
- The element used from the union depends on the status reported above:
  - sWaitForData is a structure containing information used to instruct the requesting client to wait for a time before requesting the data block again or requesting the next data block (see Section 49.11.15) - this information is only provided in the case of the status OTA_STATUS_WAIT_FOR_DATA
  - sBlockPayloadSuccess is a structure containing a requested data block and associated information (see Section 49.11.13) - this data is only provided in the case of the status OTA_STATUS_SUCCESS

Parent topic: Structures

tsOTA_UpgradeEndRequestPayload The following structure contains payload data for an Upgrade End Request issued by a client to terminate/close an image download from the server:

```
typedef struct
{
    uint32 u32FileVersion;
    uint16 u16ImageType;
    uint16 u16ManufacturerCode;
           uint8  u8Status;
}tsOTA_UpgradeEndRequestPayload;
```

where:

- u32FileVersion is the file version of the upgrade image which has been downloaded
- u16ImageType is the type of the upgrade image which has been downloaded
- u16ManufacturerCode is the ZigBee-assigned number identifying the manufacturer of the client device from which the request originates
- u8Status is the reported status of the image download, one of:
  - OTA_STATUS_SUCCESS (successfully downloaded and verified)
  - OTA_STATUS_INVALID_IMAGE (downloaded but failed verification)
  - OTA_REQUIRE_MORE_IMAGE (other images needed)
  - OTA_STATUS_ABORT (download in progress is to be aborted)

Parent topic: Structures

tsOTA_UpgradeEndResponsePayload The following structure contains payload data for an Upgrade End Response issued by the server (as the result of an Upgrade End Request from a client):

```
typedef struct
{
    uint32 u32UpgradeTime;
    uint32 u32CurrentTime;
    uint32 u32FileVersion;
    uint16 u16ImageType;
    uint16 u16ManufacturerCode;
}tsOTA_UpgradeEndResponsePayload;
```

where:

- u32UpgradeTime is the UTC time, in seconds, at which the client should upgrade the running image with the downloaded image. If the server does not support UTC time (indicated by a zero value for u32CurrentTime), the client should interpret this value as a time delay before performing the image upgrade
- u32CurrentTime is the current UTC time, in seconds, on the server. If UTC time is not supported by the server, this value should be set to zero. If this value is set to 0xFFFFFFFF, this indicates that the client should wait for an upgrade command from the server before performing the image upgrade

Note: If the client does not support UTC time but both of the above time values are non-zero, the client will take the difference between the two times as a time delay before performing the image upgrade.

- u32FileVersion is the file version of the downloaded application image (a wild card value of 0xFFFFFFFF can be used when the same response is sent to client devices from different manufacturers)
- u16ImageType is the type of the downloaded application image (a wild card value of 0xFFFF can be used when the same response is sent to client devices from different manufacturers)
- u16ManufacturerCode is the manufacturer code that was received from the client in the Upgrade End Request message (a wild card value of 0xFFFF can be used when the same response is sent to client devices from different manufacturers)

Parent topic: Structures

tsOTA_SuccessBlockResponsePayload The following structure contains payload data for an Image Block Response which reports 'success' and therefore contains a block of image data (see Section 49.11.10):

```
typedef struct
{
    uint8* pu8Data;
           uint32 u32FileOffset;
           uint32 u32FileVersion;
           uint16 u16ImageType;
           uint16 u16ManufacturerCode;
    uint8  u8DataSize;
}tsOTA_SuccessBlockResponsePayload;
```

where:

- pu8Data is a pointer to the start of the data block being transferred
- u32FileOffset is the offset, in bytes, of the start of the data block from the start of the image (normally, the same offset as specified in the Image Block Request)

- u32FileVersion is the file version of the upgrade image to which the included data block belongs
- u16ImageType is the type of the upgrade image to which the included data block belongs
- u16ManufacturerCode is the manufacturer code that was received from the client in the Image Block Request
- u8DataSize is the length, in bytes, of the included data block (this must be less than or equal to the maximum data block length for the client, specified in the Image Block Request)

Parent topic: Structures

tsOTA_BlockResponseEvent The following structure contains payload data for an Image Block Response containing data other than upgrade image data.

```
typedef struct
{
    uint8    u8Status;
    uint8   *pu8Data;
    uint8    u8DataSize;
}tsOTA_BlockResponseEvent;
```

where:

- u8Status indicates whether a suitable upgrade image is available:
  - OTA_STATUS_SUCCESS: A suitable image is available
  - OTA_STATUS_NO_IMAGE_AVAILABLE: No suitable image is available
- pu8Data is a pointer to the start of the data block being transferred
- u8DataSize is the length, in bytes, of the included data block (this must be less than or equal to the maximum data block length for the client, specified in the Image Block Request)

Parent topic: Structures

tsOTA_WaitForData The following structure contains time information for an Image Block Response. It can be used by a response which reports 'failure', to instruct the client to re-request the data block after a certain waiting time (see Section 49.11.10). It can also be used in 'rate limiting' to specify a new value for the 'block request delay' attribute on the client.

```
typedef struct
{
    uint32 u32CurrentTime;
    uint32 u32RequestTime;
    uint16 u16BlockRequestDelayMs;
}tsOTA_WaitForData;
```

where:

- u32CurrentTime is the current UTC time, in seconds, on the server. If UTC time is not supported by the server, this value should be set to zero
- u32RequestTime is the UTC time, in seconds, at which the client should re-issue an Image Block Request. If the server does not support UTC time (indicated by a zero value for u32CurrentTime), the client should interpret this value as a time delay before re-issuing an Image Block Request

Note: If the client does not support UTC time but both of the above values are non-zero, the client will take the difference between the two times as a time delay before re-issuing an Image Block Request.

- u16BlockRequestDelayMs is used in 'rate limiting' to specify the value of the 'block request delay' attribute for the client - this is minimum time, in milliseconds, that the client must wait between consecutive block requests (the client will update the local attribute with this value). If the server does not support rate limiting or does not need to limit the download rate to the client, this field must be set to 0

Parent topic: Structures

tsOTA_WaitForDataParams The following structure is used in the tsOTA_CallBackMessage structure (see Section 49.11.21) on an OTA Upgrade server. It contains the data needed to notify a client that rate limiting is required or the client must wait to receive an upgrade image.

```
typedef struct
{
   bool_t             bInitialized;
   uint16             u16ClientAddress;
   tsOTA_WaitForData  sWaitForDataPyld;
}tsOTA_WaitForDataParams;
```

where:

- bInitialized is a boolean flag indicating the server's request to the client:
  - TRUE - Implement rate limiting or wait to receive upgrade image
  - FALSE - Otherwise
- u16ClientAddress contains the 16-bit network address of the client
- sWaitForDataPyld is a structure containing the payload for an Image Block Response with status OTA_STATUS_WAIT_FOR_DATA (see Section49.11.15)

Parent topic: Structures

tsOTA_PageReqServerParams The following structure is used in the tsOTA_CallBackMessage structure (see Section 49.11.21) on an OTA Upgrade server. It contains the data from an Image Page Request received from a client.

```
typedef struct
{
   uint8                      u8TransactionNumber;
   bool_t                      bPageReqRespSpacing;
   uint16                     u16DataSent;
   tsOTA_ImagePageRequest     sPageReq;
   tsZCL_ReceiveEventAddress  sReceiveEventAddress;
}tsOTA_PageReqServerParams;
```

where:

- u8TransactionNumber is the Transaction Sequence Number (TSN) which is used in the Image Page Request
- bPageReqRespSpacing is a boolean used to request a spacing between consecutive Image Block Responses:
  - TRUE - Implement spacing
  - FALSE - Otherwise
- u16DataSent indicates the number of data bytes contained in the Image Page Request
- sPageReq is a structure containing the payload data from the Image Page Request (see Section 49.11.9)

- sReceiveEventAddress contains the address of the OTA Upgrade client that made the page request

Parent topic: Structures

tsOTA_PersistedData The following structure contains the persisted data that is stored in Flash memory using the NVM module:

```
typedef struct
{
    tsCLD_AS_Ota sAttributes;
    uint32 u32FunctionPointer;
    uint32 u32RequestBlockRequestTime;
    uint32 u32CurrentFlashOffset;
    uint32 u32TagDataWritten;
    uint32 u32Step;
    uint16 u16ServerShortAddress;
#ifdef OTA_CLD_ATTR_REQUEST_DELAY
    bool_t bWaitForBlockReq;
#endif
    uint8 u8ActiveTag[OTA_TAG_HEADER_SIZE];
    uint8 u8PassiveTag[OTA_TAG_HEADER_SIZE];
    uint8 au8Header[OTA_MAX_HEADER_SIZE];
    uint8 u8Retry;
    uint8 u8RequestTransSeqNo;
    uint8 u8DstEndpoint;
    bool_t bIsCoProcessorImage;
    bool_t bIsSpecificFile;
    bool_t bIsNullImage;
    uint8  u8CoProcessorOTAHeaderIndex;
    uint32 u32CoProcessorImageSize;
    uint32 u32SpecificFileSize;
#ifdef OTA_PAGE_REQUEST_SUPPORT
    tsOTA_PageReqParams sPageReqParams;
#endif
#if (OTA_MAX_CO_PROCESSOR_IMAGES != 0)
    uint8 u8NumOfDownloadableImages;
#endif
#ifdef OTA_INTERNAL_STORAGE
    uint8 u8Buf[4];
#endif
}tsOTA_PersistedData;
```

The fields are for internal use and no knowledge of them is required.

Parent topic: Structures

tsOTA_QuerySpecificFileRequestPayload The following structure contains the payload for a Query Specific File Request which is issued by an OTA Upgrade client to request a device-specific file from the server.

```
typedef struct
{
    uint64 u64RequestNodeAddress;
    uint16 u16ManufacturerCode;
    uint16 u16ImageType;
    uint32 u32FileVersion;
    uint16 u16CurrentZibgeeStackVersion;
}tsOTA_QuerySpecificFileRequestPayload;
```

where:

- u64RequestNodeAddress is the IEEE/MAC address of the node requesting the device-specific file from the server
- u16ManufactuerCode is the ZigBee-assigned manufacturer code of the requesting node (0xFFFF is used to indicate any manufacturer)
- u16ImageType indicates the requested file type - one of the reserved values that are assigned to the device-specific file types (the value should be in the range 0xFFC0 to 0xFFFE, but only 0xFFC0 to 0xFFC2 are currently in use)
- 32FileVersion contains the release and build numbers of the application and stack that correspond to the device-specific file - for details of the format, refer to the *ZigBee Over-the-Air Upgrading Cluster Specification (095264)*
- u16CurrentZ``ig``beeStackVersion contains the version of ZigBee stack that is currently running on the client

Parent topic: Structures

tsOTA_QuerySpecificFileResponsePayload The following structure contains the payload for a Query Specific File Response which is issued by an OTA Upgrade server in response to a request for a device-specific file.

```
typedef struct
{
    uint32 u32FileVersion;
    uint32 u32ImageSize;
    uint16 u16ImageType;
    uint16 u16ManufacturerCode;
    uint8 u8Status;
}tsOTA_QuerySpecificFileResponsePayload;
```

where:

- 32FileVersion contains the release and build numbers of the application and stack that correspond to the device-specific file - this field will take the same value as the equivalent field in the corresponding Query Specific File Request (see Section 49.11.19)
- u32ImageSize is the size of the requested file, in bytes
- u16ImageType indicates the requested file type - this field will take the same value as the equivalent field in the corresponding Query Specific File Request (see Section 49.11.19)
- u16ManufactuerCode is the ZigBee-assigned manufacturer code of the requesting node - this field will take the same value as the equivalent field in the corresponding Query Specific File Request (see Section 49.11.19)
- u8Status indicates whether a suitable file is available for download:
  - OTA_STATUS_SUCCESS: A suitable file is available
  - OTA_STATUS_NO_IMAGE_AVAILABLE: No suitable file is available
    - The other elements of the structure are only included in the case of success.

Parent topic: Structures

tsOTA_CallBackMessage For an OTA event, the eEventType field of the tsZCL_CallBackEvent structure is set to E_ZCL_CBET_CLUSTER_CUSTOM. This event structure also contains an element sClusterCustomMessage, which is itself a structure containing a field pvCustomData. This field is a pointer to the following tsOTA_CallBackMessage structure:

```
typedef struct
{
    teOTA_UpgradeClusterEvents      eEventId;
#ifdef OTA_CLIENT
    tsOTA_PersistedData sPersistedData;
    uint8 au8ReadOTAData[OTA_MAX_BLOCK_SIZE];
    uint8 u8NextFreeImageLocation;
    uint8 u8CurrentActiveImageLocation;
#endif
#ifdef OTA_SERVER
    tsCLD_PR_Ota aServerPrams[OTA_MAX_IMAGES_PER_ENDPOINT+OTA_MAX_CO_
↪PROCESSOR_IMAGES];
    tsOTA_AuthorisationStruct               sAuthStruct;
    uint8  u8ServerImageStartSector;
    bool bIsOTAHeaderCopied;
    uint8 au8ServerOTAHeader[OTA_MAX_HEADER_SIZE+OTA_TAG_HEADER_SIZE];
    tsOTA_WaitForDataParams  sWaitForDataParams;
#ifdef OTA_PAGE_REQUEST_SUPPORT
    tsOTA_PageReqServerParams  sPageReqServerParams;
#endif
#endif
    uint8  u8ImageStartSector[OTA_MAX_IMAGES_PER_ENDPOINT];
    uint8 au8CAPublicKey[22];
    uint8 u8MaxNumberOfSectors;
    union
    {
        tsOTA_ImageNotifyCommand              sImageNotifyPayload;
        tsOTA_QueryImageRequest               sQueryImagePayload;
        tsOTA_QueryImageResponse              sQueryImageResponsePayload;
        tsOTA_BlockRequest                    sBlockRequestPayload;
        tsOTA_ImagePageRequest                sImagePageRequestPayload;
        tsOTA_ImageBlockResponsePayload       sImageBlockResponsePayload;
        tsOTA_UpgradeEndRequestPayload        sUpgradeEndRequestPayload;
        tsOTA_UpgradeEndResponsePayload       sUpgradeResponsePayload;
        tsOTA_QuerySpecificFileRequestPayload sQuerySpFileRequestPayload;
        tsOTA_QuerySpecificFileResponsePayload
              sQuerySpFileResponsePayload;
        teZCL_Status                          eQueryNextImgRspErrStatus;
        tsOTA_SignerMacVerify                 sSignerMacVerify;
        tsOTA_ImageVersionVerify              sImageVersionVerify;
        tsOTA_UpgradeDowngradeVerify          sUpgradeDowngradeVerify;
    }uMessage;
}tsOTA_CallBackMessage;
```

where:

- eEventId is the OTA event type (enumerations are detailed in Section49.12.2)
- sPersistedData is the structure (see Section 49.11.18) which contains the persisted data that is stored in Flash memory using the NVM module on the client
- au8ReadOTAData is an array containing the payload data from an Image Block Response
- u8NextFreeImageLocation identifies the next free image location where a new upgrade image can be stored
- u8CurrentActiveImageLocation identifies the location of the currently active image on the client
- aServerPrams is an array containing the server data for each image which can be updated by application
- sAuthStruct is a structure which stores the authorisation state and list of client devices that are authorised for OTA upgrade

- u8ServerImageStartSector identifies the server self-image start-sector
- bIsOTAHeaderCopied specifies whether the new OTA header is copied (TRUE) or not (FALSE)
- au8ServerOTAHeader specifies the current server OTA header
- sWaitForDataParams is a structure containing time information that may need to be modified by the server for inclusion in an Image Block Response (for more information, refer to Section 49.11.15)
- sPageReqServerParams is a structure containing page request information that may need to be modified by the server
- u8ImageStartSector is used to store the image start-sector for each image which is stored or will be stored in the devices internal Flash memory - note that this variable assumes a 32-Kbyte sector size and so, for example, if

  64-Kbyte sectors are used, its value will be twice the actual start-sector value
- au8CAPublicKey specifies the CA public key
- u8MaxNumberOfSectors specifies the maximum number of sectors to be used per image
- uMessage is a union containing the command payload in one of the following forms (depending on the command specified by eEventId):
  - sImageNotifyPayload is a structure containing the payload of an Image Notify command
  - sQueryImagePayload is a structure containing the payload of a Query Next Image Request
  - sQueryImageResponsePayload is a structure containing the payload of a Query Next Image Response
  - sBlockRequestPayload is a structure containing the payload of an Image Block Request
  - sImagePageRequestPayload is a structure containing the payload of an Image Page Request
  - sImageBlockResponsePayload is a structure containing the payload of an Image Block Response
  - sUpgradeEndRequestPayload is a structure containing the payload of an Upgrade End Request
  - sUpgradeResponsePayload is a structure containing the payload of an Upgrade End Response
  - sQuerySpFileRequestPayload is a structure containing the payload of a Query Specific File Request
  - sQuerySpFileResponsePayload is a structure containing the payload of a Query Specific File Response
  - eQueryNextImgRspErrStatus is the status returned from the query image response command handler and can be passed up to the application when there is an error via the callback event E_CLD_OTA_COMMAND_QUERY_NEXT_IMAGE_RESPONSE_

    ERROR. The returned status value will be either E_ZCL_ERR_INVALID_IMAGE_SIZE or E_ZCL_ERR_INVALID_IMAGE_VERSION
  - sSignerMacVerify is a structure containing the signer's IEEE/MAC address from a new upgrade image and a status field (which is set by the application after verifying the signer's address)
  - sImageVersionVerify is a structure containing the image version received in the query next image response and status field (which is set by the application after verifying the image version)

  - sUpgradeDowngradeVerify is a structure containing the image version received in the upgrade end response and a status field (which is set by the application after verifying the image version)

Parent topic: Structures

tsCLD_PR_Ota The following structure contains server parameter data that can be pre-set using the function **eOTA_SetServerParams()** and obtained using **eOTA_GetServerData()**:

```
typedef struct
{
    uint8* pu8Data;
    uint32 u32CurrentTime;
    uint32 u32RequestOrUpgradeTime;
    uint8  u8QueryJitter;
    uint8  u8DataSize;
} tsCLD_PR_Ota;
```

where:

- pu8Data is a pointer to the start of a block of data
- u32CurrentTime is the current UTC time, in seconds, on the server. If UTC time is not supported by the server, this value should be set to zero
- u32RequestOrUpgradeTime is used by the server as the 'request time' and the 'upgrade time' when sending responses to clients:
  - As a 'request time', the value may be included in an Image Block Response (see Section 49.11.10 and Section 49.11.15)
  - As an 'upgrade time', the value will be included in an Upgrade End Response (see Section 49.11.12)
- u8QueryJitteris a value between 1 and 100 (inclusive) which is used by a receiving client to decide whether to reply to an Image Notify message - for information on 'Query Jitter', refer to Section 49.7
- u8DataSize is the length, in bytes, of the data block pointed to by pu8Data

Parent topic: Structures

tsCLD_AS_Ota This structure contains attribute values which are stored as part of the persisted data in Flash memory:

```
typedef struct
{
    uint64 u64UgradeServerID;
    uint32 u32FileOffset;
    uint32 u32CurrentFileVersion;
    uint16 u16CurrentStackVersion;
    uint32 u32DownloadedFileVersion;
    uint16 u16DownloadedStackVersion;
    uint8  u8ImageUpgradeStatus;
    uint16 u16ManfId;
    uint16 u16ImageType;
    uint16 u16MinBlockRequestDelay;
} tsCLD_AS_Ota;
where the structure elements are OTA Upgrade cluster attribute values, as described in [Section 49.3](ota_
↪upgrade_cluster_structure_and_attributes.md#id_accc84e1-e4af-4078-b61f-af69b4b4314c).
```

Parent topic: Structures

tsOTA_ImageVersionVerify The following structure contains the data for an event of the type E_CLD_OTA_INTERNAL_COMMAND_VERIFY_IMAGE_VERSION.

```
typedef struct
{
    uint32 u32NotifiedImageVersion;
    uint32 u32CurrentImageVersion;
    teZCL_Status eImageVersionVerifyStatus;
}tsOTA_ImageVersionVerify;
```

where:

- u32NotifiedImageVersion is the version received in the query next image response
- u32CurrentImageVersion is the version of the running image
- eImageVersionVerifyStatus is a status field which should be updated to E_ZCL_SUCCESS or E_ZCL_FAIL by the application after checking the received image version, to indicate whether the upgrade image has a valid image version

Parent topic: Structures

tsOTA_UpgradeDowngradeVerify The following structure contains the data for an event of the type E_CLD_OTA_INTERNAL_COMMAND_SWITCH_TO_UPGRADE_DOWNGRADE.

```
typedef struct
{
    uint32 u32DownloadImageVersion;
    uint32 u32CurrentImageVersion;
    teZCL_Status eUpgradeDowngradeStatus;
}tsOTA_UpgradeDowngradeVerify;
```

where:

- u32DownloadImageVersion is the version received in upgrade end response
- u32CurrentImageVersion is the version of running image
- eImageVersionVerifyStatus is a status field which should be updated to E_ZCL_SUCCESS or E_ZCL_FAIL by the application after checking the received image version, to indicate whether the upgrade image has a valid image version

Parent topic:*OTA Upgrade cluster*

Enumerations

teOTA_Cluster The following enumerations represent the OTA Upgrade cluster attributes:

```
typedef enum
{
    E_CLD_OTA_ATTR_UPGRADE_SERVER_ID,
    E_CLD_OTA_ATTR_FILE_OFFSET,
    E_CLD_OTA_ATTR_CURRENT_FILE_VERSION,
    E_CLD_OTA_ATTR_CURRENT_ZIGBEE_STACK_VERSION,
    E_CLD_OTA_ATTR_DOWNLOADED_FILE_VERSION,
    E_CLD_OTA_ATTR_DOWNLOADED_ZIGBEE_STACK_VERSION,
    E_CLD_OTA_ATTR_IMAGE_UPGRADE_STATUS,
    E_CLD_OTA_ATTR_MANF_ID,
```

(continues on next page)

(continued from previous page)

```
    E_CLD_OTA_ATTR_IMAGE_TYPE,
    E_CLD_OTA_ATTR_REQUEST_DELAY
}teOTA_Cluster;
```

The above enumerations are described in the table below.

Enumeration	Attribute
E_CLD_OTA_ATTR_UPGRADE_SERVER_ID	Upgrade Server ID
E_CLD_OTA_ATTR_FILE_OFFSET	File Offset
E_CLD_OTA_ATTR_CURRENT_FILE_VERSION	Current File Version
E_CLD_OTA_ATTR_CURRENT_ZIGBEE_STACK_VERSION	Current ZigBee Stack Version
E_CLD_OTA_ATTR_DOWNLOADED_FILE_VERSION	Downloaded File Version
E_CLD_OTA_ATTR_DOWNLOADED_ZIGBEE_STACK_VERSIO	Downloaded ZigBee Stack Version
E_CLD_OTA_ATTR_IMAGE_UPGRADE_STATUS	Image Upgrade Status
E_CLD_OTA_ATTR_MANF_ID	Manufacturer ID
E_CLD_OTA_ATTR_IMAGE_TYPE	Image Type
E_CLD_OTA_ATTR_REQUEST_DELAY	Minimum Block Request Delay

The above attributes are described in Section 49.3.

Parent topic: Enumerations

teOTA_UpgradeClusterEvents The following enumerations represent the OTA Upgrade cluster events:

```
typedef enum
{
    E_CLD_OTA_COMMAND_IMAGE_NOTIFY,
    E_CLD_OTA_COMMAND_QUERY_NEXT_IMAGE_REQUEST,
    E_CLD_OTA_COMMAND_QUERY_NEXT_IMAGE_RESPONSE,
    E_CLD_OTA_COMMAND_BLOCK_REQUEST,
    E_CLD_OTA_COMMAND_PAGE_REQUEST,
    E_CLD_OTA_COMMAND_BLOCK_RESPONSE,
    E_CLD_OTA_COMMAND_UPGRADE_END_REQUEST,
    E_CLD_OTA_COMMAND_UPGRADE_END_RESPONSE,
    E_CLD_OTA_COMMAND_QUERY_SPECIFIC_FILE_REQUEST,
    E_CLD_OTA_COMMAND_QUERY_SPECIFIC_FILE_RESPONSE,
    E_CLD_OTA_INTERNAL_COMMAND_TIMER_EXPIRED,
    E_CLD_OTA_INTERNAL_COMMAND_SAVE_CONTEXT,
    E_CLD_OTA_INTERNAL_COMMAND_OTA_DL_ABORTED,
    E_CLD_OTA_INTERNAL_COMMAND_POLL_REQUIRED,
    E_CLD_OTA_INTERNAL_COMMAND_RESET_TO_UPGRADE,
    E_CLD_OTA_INTERNAL_COMMAND_LOCK_FLASH_MUTEX,
    E_CLD_OTA_INTERNAL_COMMAND_FREE_FLASH_MUTEX,
    E_CLD_OTA_INTERNAL_COMMAND_SEND_UPGRADE_END_RESPONSE,
    E_CLD_OTA_INTERNAL_COMMAND_CO_PROCESSOR_BLOCK_RESPONSE,
    E_CLD_OTA_INTERNAL_COMMAND_CO_PROCESSOR_DL_ABORT,
    E_CLD_OTA_INTERNAL_COMMAND_CO_PROCESSOR_IMAGE_DL_COMPLETE,
    E_CLD_OTA_INTERNAL_COMMAND_CO_PROCESSOR_SWITCH_TO_NEW_IMAGE,
    E_CLD_OTA_INTERNAL_COMMAND_CO_PROCESSOR_IMAGE_BLOCK_REQUEST,
    E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_BLOCK_RESPONSE,
    E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_DL_ABORT,
    E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_DL_COMPLETE,
    E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_USE_NEW_FILE,
    E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_NO_UPGRADE_END_RESPONSE,
```

(continues on next page)

(continued from previous page)

```
    E_CLD_OTA_COMMAND_QUERY_NEXT_IMAGE_RESPONSE_ERROR,
    E_CLD_OTA_INTERNAL_COMMAND_VERIFY_SIGNER_ADDRESS,
    E_CLD_OTA_INTERNAL_COMMAND_RCVD_DEFAULT_RESPONSE,
    E_CLD_OTA_INTERNAL_COMMAND_VERIFY_IMAGE_VERSION,
    E_CLD_OTA_INTERNAL_COMMAND_SWITCH_TO_UPGRADE_DOWNGRADE,
    E_CLD_OTA_INTERNAL_COMMAND_REQUEST_QUERY_NEXT_IMAGES,
    E_CLD_OTA_INTERNAL_COMMAND_OTA_START_IMAGE_VERIFICATION_IN_LOW_
↪PRIORITY,
    E_CLD_OTA_INTERNAL_COMMAND_FAILED_VALIDATING_UPGRADE_IMAGE,
    E_CLD_OTA_INTERNAL_COMMAND_FAILED_COPYING_SERIALIZATION_DATA
}teOTA_UpgradeClusterEvents;
```

The above enumerations are described in the table below.

Enumeration	Event Description
E_CLD_OTA_COMMAI	Generated on client when an Image Notify message is received from the server to indicate that a new application image is available for download
E_CLD_OTA_COMMAI	Generated on server when a Query Next Image Request is received from a client to enquire whether a new application image is available for download
E_CLD_OTA_COMMAI	Generated on client when a Query Next Image Response is received from the server (in response to a Query Next Image Request) to indicate whether a new application image is available for download
E_CLD_OTA_COMMAI	Generated on server when an Image Block Request is received from a client to request a block of image data as part of a download
E_CLD_OTA_COMMAI	Generated on server when an Image Page Request is received from a client to request a page of image data as part of a download
E_CLD_OTA_COMMAI	Generated on client when an Image Block Response is received from the server (in response to an Image Block Request) and contains a block of image data which is part of a download
E_CLD_OTA_COMMAI	Generated on server when an Upgrade End Request is received from a client to indicate that the complete image has been downloaded and verified
E_CLD_OTA_COMMAI	Generated on client when an Upgrade End Response is received from the server (in response to an Upgrade End Request) to confirm the end of a download
E_CLD_OTA_COMMAI	Generated on server when a Query Specific File Request is received from a client to request a particular application image
E_CLD_OTA_COMMAI	Generated on client when a Query Specific File Response is received from the server (in response to a Query Specific File Request) to indicate whether the requested application image is available for download
E_CLD_OTA_INTERNA	Generated on client to notify the application that the local one-second timer has expired
E_CLD_OTA_INTERNA	Generated on server or client to prompt the application to store context data in Flash memory
E_CLD_OTA_INTERNA	Generated on a client if the received image is invalid or the client has aborted the image download (allowing the application to request the new image again)
E_CLD_OTA_INTERNA	Generated on client to prompt the application to poll the server for a new application image
E_CLD_OTA_INTERNA	Generated on client to notify the application that the stack is going to reset the device
E_CLD_OTA_INTERNA FLASH_MUTEX	Generated on server or client to prompt the application to lock the mutex used for accesses to external Flash

memory

| |E_CLD_OTA_INTERNAL_COMMAND_FREE_-FLASH_MUTEX|Generated on server or client to prompt the application to unlock the mutex used for accesses to external Flash memory| |E_CLD_OTA_INTERNAL_COMMAND_SEND_UPGRADE_END_RESPONSE|Generated on server to notify the application that the stack is going to send an Upgrade End Response to a client| |E_CLD_OTA_INTERNAL_COMMAND_CO_PROCESSOR_BLOCK_RESPONSE|Generated on client to notify the application that Image Block Response has been received for co-processor image| |E_CLD_OTA_INTERNAL_COMMAND_CO_PROCESSOR_DL_ABORT|Generated on client to notify the application that download of co-processor image from the server has been aborted| |E_CLD_OTA_INTERNAL_COMMAND_CO_PROCESSOR_IMAGE_DL_COMPLETE|Generated on client to notify the application that download of co-processor image from the server has completed| |E_CLD_OTA_INTERNAL_COMMAND_CO_PROCESSOR_SWITCH_TO_NEW_IMAGE|Generated on client to notify the application that the upgrade time for a previously downloaded co-processor image has been reached (this event is generated after receiving the Upgrade End Response which contains the upgrade time)| |E_CLD_OTA_INTERNAL_COMMAND_CO_PROCESSOR_IMAGE_BLOCK_REQUEST|Generated on server when an Image Block Request is

received from a client to request a block of image data

as part of a download and the server finds that the required image is stored in the co-processor's external storage device

| |E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_BLOCK_RESPONSE|Generated on client when an Image Block Response is received from server as part of a device-specific file download - the event contains a block of file data which the client stores in an appropriate location| |E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_DL_ABORT|Generated on client when the final Image Block Response of a device-specific file download has been received from the server| |E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_DL_COMPLETE|Generated on client following a device-specific file download to indicate that the upgrade time has been reached and the file can now be used by the client| |E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_USE_NEW_FILE|Generated to indicate that a device-specific file download is being aborted and any received data must be discarded by the application| |E_CLD_OTA_INTERNAL_COMMAND_SPECIFIC_FILE_NO_UPGRADE_END_RESPONSE|Generated to indicate that no Upgrade End Response has been received for a device-specific file download (after three attempts to obtain one)| |E_CLD_OTA_COMMAND_QUERY_NEXT_IMAGE_RESPONSE_ERROR|This event is generated on the client when a Query Next Image Response message is received from the server, in response to a Query Next Image Request with a status of Invalid Image Size.| |E_CLD_OTA_INTERNAL_COMMAND_VERIFY_SIGNER_ADDRESS|This event is generated to prompt the application to verify the signer address received in a new OTA upgrade image. This event gives control to the application to verify that the new upgrade image came from a trusted source. After checking the signer address, the application should set the status field of the event to E_ZCL_SUCCESS (valid source) or E_ZCL_FAIL (invalid source).| |E_CLD_OTA_INTERNAL_COMMAND_RCVD_DEFAULT_RESPONSE|This event is generated on the client when a default response message is received from the server, in response to a Query Next Image Request, Image Block Request or Upgrade End Request. This is an internal ZCL event that results in an OTA download being aborted, thus activating the callback function for the event E_CLD_OTA_INTERNAL_COMMAND_OTA_DL_ABORTED.| |E_CLD_OTA_INTERNAL_COMMAND_VERIFY_IMAGE_VERSION|This event is generated to prompt the application to verify the image version received in a Query Next Image Response. This event allows the application to verify that the new upgrade image has a valid image version. After checking the image version, the application should set the status field of the event to E_ZCL_SUCCESS (valid version) or E_ZCL_FAIL (invalid version).| |E_CLD_OTA_INTERNAL_COMMAND_SWITCH_TO_UPGRADE_DOWNGRADE|This event is generated to prompt the application to verify the image version received in an upgrade end response. This event allows the application to verify that the new upgrade image has a valid image version.

After checking the image version, the application should set the status field of the event to E_ZCL_SUCCESS (valid version) or E_ZCL_FAIL (invalid version).

| |E_CLD_OTA_INTERNAL_COMMAND_REQUEST_QUERY_NEXT_IMAGES|This event is generated on the client when a co-processor image also requires the client to update its own image. After the first file is downloaded (co-processor image) this event notifies the application to allow it to send a Query Next Image command for its own upgrade image, using the function **eOTA_ClientQueryNextImageRequest()**.| |E_CLD_OTA_INTERNAL_COMMAND_OTA_START_IMAGE_VERIFICATION_IN_LOW_PRIORITY|This event is generated to prompt the application to verify the downloaded JN516x client image from a low priority task. Once the low priority task is running, the application should call **eOTA_VerifyImage()** to start image verification.| |E_CLD_OTA_INTERNAL_COMMAND_FAILED_VALIDATING_UPGRADE_IMAGE|This event is generated on the client when the validation of a new upgrade image fails. This validation takes place when the upgrade time is reached.| |E_CLD_OTA_INTERNAL_COMMAND_FAILED_COPYING_SERIALIZATION_DATA|This event is generated on the client when the copying of serialization data from the active image to the new upgrade image fails. This process takes place after image validation (if applicable) are completed successfully.|

The above events are described in more detail in Section 49.9.

Parent topic: Enumerations

eOTA_AuthorisationState The following enumerations represent the authorisation options concerning which clients are allowed to obtain upgrade images from the server:

```
typedef enum
{
   E_CLD_OTA_STATE_ALLOW_ALL,
   E_CLD_OTA_STATE_USE_LIST
}eOTA_AuthorisationState;
```

The above enumerations are described in the table below.

Enumeration	Description
E_CLD_OTA_STATE_ALLOW	Allow all clients to obtain upgrade images from this server
E_CLD_OTA_STATE_USE_LI	Only allow clients in authorisation list to obtain upgrade images from this server

Parent topic: Enumerations

teOTA_ImageNotifyPayloadType The following enumerations represent the payload options for an Image Notify message issued by the server:

```
typedef enum
{
   E_CLD_OTA_QUERY_JITTER,
   E_CLD_OTA_MANUFACTURER_ID_AND_JITTER,
   E_CLD_OTA_ITYPE_MDID_JITTER,
   E_CLD_OTA_ITYPE_MDID_FVERSION_JITTER
}teOTA_ImageNotifyPayloadType;
```

The above enumerations are described in the table below.

Enumeration	Description
E_CLD_OTA_QUERY_JITTER	Include only 'Query Jitter' in payload
E_CLD_OTA_MANUFACTURER_ID	Include 'Manufacturer Code' and 'Query Jitter' in payload
E_CLD_OTA_ITYPE_MDID_JITTER	Include 'Image Type', 'Manufacturer Code' and 'Query Jitter' in payload
E_CLD_OTA_ITYPE_MDID_FVERSI	Include 'Image Type', 'Manufacturer Code', 'File Version' and 'Query Jitter' in payload

Parent topic: Enumerations

Parent topic:*OTA Upgrade cluster*

Compile-time options To enable the OTA Upgrade cluster in the code to be built, it is necessary to add the following to the **zcl_options.h** file:

```
#define CLD_OTA
```

In addition, to enable the cluster as a client or server or both, it is also necessary to add one or both of the following to the same file:

```
#define OTA_CLIENT
#define OTA_SERVER
```

Note: The OTA Upgrade cluster must be enabled as a client or server, as appropriate, in the application images to be downloaded using the cluster. The relevant cluster options (see below) should also be enabled for the image.

The following may also be defined in the **zcl_options.h** file.

Optional Attributes (Client only) The OTA Upgrade cluster has attributes on the client side only. The optional attributes may be specified by defining some or all of the following.

Add this line to enable the optional File Offset attribute:

```
#define OTA_CLD_ATTR_FILE_OFFSET
```

Add this line to enable the optional Current File Version attribute:

```
#define OTA_CLD_ATTR_CURRENT_FILE_VERSION
```

Add this line to enable the optional Current ZigBee Stack Version attribute:

```
#define OTA_CLD_ATTR_CURRENT_ZIGBEE_STACK_VERSION
```

Add this line to enable the optional Downloaded File Version attribute:

```
#define OTA_CLD_ATTR_DOWNLOADED_FILE_VERSION
```

Add this line to enable the optional Downloaded ZigBee Stack Version attribute:

```
#define OTA_CLD_ATTR_DOWNLOADED_ZIGBEE_STACK_VERSION
```

Add this line to enable the optional Manufacturer ID attribute:

```
#define        OTA_CLD_MANF_ID
```

Add this line to enable the optional Image Type attribute:

```
#define OTA_CLD_IMAGE_TYPE
```

Add this line to enable the optional Minimum Block Request Delay attribute:

```
#define OTA_CLD_ATTR_REQUEST_DELAY
```

Global Attributes Add this line to define the value (n) of the Cluster Revision attribute:

```
#define CLD_THERMOSTAT_CLUSTER_REVISION <n>
```

The default value is 1, which corresponds to the revision of the cluster in the ZCL r6 specification (see Section 2.4).

Number of Images The maximum number of images that can be stored in the Flash memory of the device of a server or client node must be specified as follows, where in this example the maximum is two images:

```
#define OTA_MAX_IMAGES_PER_ENDPOINT             2
```

Note that the active image should not be included.

OTA Block Size The maximum size of a block of image data to be transferred over the air is defined, in bytes, as follows:

```
#define OTA_MAX_BLOCK_SIZE                  100
```

If a large maximum block size is configured, it is recommended to enable fragmentation for data transfers between nodes. Fragmentation is enabled and configured on the sending and receiving nodes as described in the 'Application Design Notes' appendix of the *ZigBee 3.0 Stack User Guide (JNUG3130)*.

Page Requests The 'page request' feature can be enabled on the server and client by adding the line:

```
#define OTA_PAGE_REQUEST_SUPPORT
```

If the page request feature is enabled then the page size (in bytes) and 'response spacing' (in milliseconds) to be inserted into the Image Page Requests can be configured by defining the following macros on the client:

```
#define OTA_PAGE_REQ_PAGE_SIZE              512
#define OTA_PAGE_REQ_RESPONSE_SPACING       300
```

The above example definitions contain the default values of 512 bytes and 300 ms.

Hardware Versions in OTA Header If hardware versions will be present in the OTA header then in order to enable checks of the hardware versions on the OTA server and client, add:

```
#define OTA_CLD_HARDWARE_VERSIONS_PRESENT
```

Custom Serialization Data To maintain custom serialization data associated with binary images during upgrades on the server or client, add:

```
#define OTA_MAINTAIN_CUSTOM_SERIALISATION_DATA
```

OTA Command Acks To disable APS acknowledgements for OTA commands on the server or client, add:

```
#define OTA_ACKS_ON FALSE
```

If the above define is not included, APS acknowledgements are enabled by default. **They must be enabled for ZigBee certification**, but for increased download speed it may be convenient to disable them during application development. However, they must not be disabled if using fragmentation.

Frequency of Requests (Client only) To avoid flooding the network with continuous packet exchanges, the request messages from the client can be throttled by defining a time interval, in seconds, between consecutive requests. For example, a one-second interval is defined as follows:

```
#define OTA_TIME_INTERVAL_BETWEEN_REQUESTS 1
```

If this time interval is not defined then the time interval, in seconds, between consecutive retries of an unthrottled message request should be defined. For example, a ten-second retry interval is defined as follows:

```
#define OTA_TIME_INTERVAL_BETWEEN_RETRIES 10
```

(valid only if OTA_TIME_INTERVAL_BETWEEN_REQUESTS is not defined)

Upper Limit on Minimum Block Request Delay An upper limit on the value of the Minimum Block Request Delay attribute is defined, in seconds, as follows:

```
#define OTA_BLOCK_REQUEST_DELAY_MAX_VALUE 2
```

In the above example, the limit is set to 2 seconds. If no value is defined, the default value of this limit is 5 seconds.

Device Address Copying On a device whose application image is to be upgraded (client or server), the OTA Upgrade cluster must copy the IEEE/MAC address of the device from the old image to the new image. This copy must be enabled on the device by adding the line:

```
#define OTA_COPY_MAC_ADDRESS
```

No Security Certificate If no security certificate is to be used, it is necessary to remove references to the Certicom security certificate by including the following definition:

```
#define OTA_NO_CERTIFICATE
```

Internal Storage of OTA Upgrade Image on Client An OTA upgrade image can be stored in the devices internal Flash memory on an OTA Upgrade cluster client by including the following definition:

```
#define OTA_INTERNAL_STORAGE
```

In addition, if the OTA upgrade image is encrypted then it needs to be decrypted before being stored in internal Flash memory. This decryption can be enabled by including the following definition:

```
#define INTERNAL_ENCRYPTED
```

Parent topic:*OTA Upgrade cluster*

Build Process Special build requirements must be implemented when building applications that are to participate in OTA upgrades:

1. Certain lines must be included in the makefiles for the applications - see Section 49.14.1
2. The server and client applications must then be built - see Section 49.14.2
3. The (initial) client application must now be prepared and loaded into Flash memory of the client device - see Section 49.14.3
4. The server application must now be prepared and loaded into Flash memory of the server device - see Section 49.14.4

Modifying Makefiles In the makefiles for all applications (for server and all clients), replace the following lines:

```
$(OBJCOPY) -j .version -j .bir -j .flashheader -j .vsr_table
-j .vsr_handlers  -j .rodata -j .text -j .data -j .bss -j .heap
-j .stack -S -O binary $< $@
```

with:

```
        $(OBJCOPY) -j .version -j .bir -j .flashheader -j .vsr_table
-j .vsr_handlers -j .ro_mac_address -j .ro_ota_header  -j .rodata
-j .text -j .data -j .bss -j .heap -j .stack -S -O binary $< $@
```

Parent topic: Build Process

Building Applications The server and client applications must be built with the makefiles adapted for OTA upgrade (see Section 49.14.1). A build can be conducted from MCUXpresso as for any ZigBee PRO application - refer to the *MCUXpresso Installation and User Guide (JNUG3136)*.

The resulting binary files must then be prepared and loaded into Flash memory as described in Section 49.14.3 and Section 49.14.4.

Parent topic: Build Process

Preparing and Downloading Initial Client Image The first time that the client is programmed with an application, the binary image must be loaded into Flash memory on the client device using a Flash programming tool such as the Flash Programmer within MCUXpresso (normally only used in a development environment) or the *DK6 Production Flash Programmer (JN-SW-4407)*.

After this initial image has been loaded, all subsequent client images will be downloaded from the server to the client via the OTA Upgrade cluster.

Parent topic: Build Process

Preparing and Downloading Server Image The server device is programmed by loading a binary image into Flash memory using a Flash programming tool such as the Flash Programmer within MCUXpresso (normally only used in a development environment) or the *DK6 Production Flash Programmer (JN-SW-4407)*.

When a new client image becomes available for the server to distribute, this image must be loaded into the server.

- In a deployed and running system, this image may be supplied via a backhaul network.
- In a development environment, it may be loaded into Flash memory using the Flash Programmer within MCUXpresso.
  - However, this Flash Programmer only allows programming from the start of Flash memory. Therefore, the server application must be re-programmed into the Flash memory as well as the new client image. The server application binary and client application binary must be combined into a single binary image using the DK6 Encryption Tool (JET) before being loaded into the server. This tool is provided in the SDK and is described in the *JET User Guide (JNUG3135)*.

Note: If desired, the initial server image can also include the initial client application. Although there is no need for the server to download this first client application to the client(s), it may be stored in the server in case there is any subsequent need to re-load it into a client.

Parent topic: Build Process

Parent topic:*OTA Upgrade cluster*

OTA Configuration for Internal Flash OTA cluster is enabled through the **ZCL_options.h** file.

The OTA cluster requires initialization of the location where the upgrade image can be stored. The application provides this through ***eOTA_AllocateEndpointOTASpace*** API.

Each page on the device is 512 bytes. The usable flash size is 632 K, with 32 K typically reserved for NVM (start page 1152) and 24 K for customer data. This leaves a usable flash size for image at 576 K.

If we split it into two sections to support OTA. It means 288 K becomes maximum image size. Each 288 K section would be 576 flash pages.

This could be represented as 32 K sectors to keep in line with legacy devices.

So, for allocation to the OTA cluster:

```
uint8 u8MaxSectorPerImage = 0;
uint8 u8StartSector[1] = {9}; /* So next image starts at 9*32*1024 = 288K offset*/
u8MaxSectorPerImage = 9 ; /* 9 *32* 1024 = 288K is the maximum size of the image */
sNvmDefs.u32SectorSize = 512; /* Sector Size = 512 bytes*/
```

The OTA checks for the presence of the well-known Zigbee09 key at a fixed location within the image.

This provides a convenient mechanism to test the decryption of an encrypted image and an additional sanity check to make sure the image is a valid image to progress downloading.

Note: This is not the mechanism for a full image validation. For a better validation of an OTA image, it is recommended that for OTA an encrypted image with the CRC check is used.

Each application note has an OTA_BUILD folder which holds the OTA compatible images.

LinkKey_3.txt is required for creation of the OTA image. It holds the Key which can be used for validation purpose as described above.

The **config OTA_JN518x_Cer_Keys_HA_Light.txt**and **config OTA_JN518x_Cer_Keys_HA_Light_Generic.txt**files provide the OTA image generator with the offset for the key.

Prior to this release the values were **LinkKey_3.txt,02c0,16**, which should now be **LinkKey_3.txt,01b0,16**.

Switching to a new image After an image is programmed into flash and validated as a correct image to switch to, the following steps should then be performed. These are already done as part of the OTA cluster. However, for custom applications not using the OTA cluster, it would be a requirement to switch and run a new image.

```
  /* Offset in bytes into flash for the new image. In this example, new image is at 288K boundary*/
 u32Offset = 0x48000;
  /* Set the active image location */
  psector_SetEscoreImageData(u32Offset, 0);
  /* Disable any interrupts during the switching of the images */
  __disable_irq();
  /* Remap the vector table to point to the ROM instead of the application */
  SYSCON->MEMORYREMAP &= ~(SYSCON_MEMORYREMAP_MAP_MASK << SYSCON_
↪MEMORYREMAP_MAP_SHIFT);
  /* Prevent entering into Low Power Mode when we reset */
  PMC->CTRL &= ~(PMC_CTRL_LPMODE_MASK << PMC_CTRL_LPMODE_SHIFT);
  /* Initiate reset */
  NVIC_SystemReset();
```

Parent topic:OTA Configuration for Internal Flash

Parent topic:*OTA Upgrade cluster*

Part XIII: Appendices This part comprises nine appendices covering topics that include mutex callbacks, attribute reporting, attribute discovery, custom endpoints, manufacturer-specific attributes and commands, the storage of OTA upgrade applications in the devices Internal or External Flash memory, the OTA upgrade of nodes comprising two processors, example code fragments and a glossary of terms.

Appendix A: Mutex callbacks The mutexes are designed such that a call to **ZPS_u8GrabMutexLock()** must be followed by a call to **ZPS_u8ReleaseMutexLock()**. In addition, the call must not be followed by another call to **ZPS_u8GrabMutexLock()**, which means the mutexes are binary rather than counting. This can cause problems if the ZCL takes a mutex via the callback function and then the application wants to lock the mutex to access the shared device structures. Some ZCL clusters also invoke the callback function with E_ZCL_CBET_LOCK_MUTEX multiple times. The counting mutex code below should be used in the application code. When the application wants to access the shared structure, it should call the **vLockZCLMutex()** function (shown in the code extract below), rather than **ZPS_u8GrabMutexLock()**, so that it also participates in the counting mutex rather than directly taking the binary ZPS mutex-protection. Similarly, the shared structure should be released using **vUnlockZCLMutex()**.

The code below uses a single resource for all endpoints and the general callback function. It defines a file scope counter that is the mutex count related to the resource.

At the top of the application source file, create the count and lock/unlock mutex function prototypes (these prototypes may be placed in a header file, if desired):

```
uint32 u32ZCLMutexCount = 0;
void vLockZCLMutex(void);
void vUnlockZCLMutex(void);
```

In both **cbZCL_GeneralCallback()** and **cbZCL_EndpointCallback()**, make the calls:

```
switch(psEvent->eEventType)
 {
 case E_ZCL_CBET_LOCK_MUTEX:
            vLockZCLMutex();
          break;
     case E_ZCL_CBET_UNLOCK_MUTEX:
       vUnlockZCLMutex();
          break;
```

Define the lock/unlock mutex functions and call them from the application when accessing any ZCL shared structure:

```
void vLockZCLMutex(void)
{
       if (u32ZCLMutexCount == 0)
       {
             ZPS_u8GrabMutexLock(mutexZCL,0);
       }
       u32ZCLMutexCount++;
}
void vUnlockZCLMutex(void)
{
       u32ZCLMutexCount--;
       if (u32ZCLMutexCount == 0)
       {
             ZPS_u8ReleaseMutexLock(mutexZCL,0);
       }
}
```

Appendix B: Attribute reporting Attribute reporting involves sending attribute values unsolicited from the cluster server to a client - that is, pushing values from server to client without the client needing to request the values. This mechanism reduces network traffic compared with the client polling the server for attribute values. It also allows a sleeping server to report its attribute values while it is awake.

The server sends an 'attribute report' to the client, where this report can be issued in one of the following ways:

- by a function call in the user application (on the server device)
- automatically by the ZCL (triggered by a change in the attribute value or periodically)

The rules for automatic reporting (see Appendix B.1) can be configured by a remote client by sending a 'configure reporting' command to the server. The same rules apply to 'default reporting' (see Appendix B.2), but are configured locally on the server. The configuration of attribute reporting is described in Appendix B.3. Remote devices can also query the attribute reporting configuration of the server, as described in Appendix B.6.

Sending and receiving attribute reports are described in Appendix B.4 and Appendix B.5.

Attention: Attribute reporting is an optional feature and is not supported by all devices.

Appendix B.1: Automatic attribute reporting Automatic attribute reporting involves two mechanisms:

- A report is triggered by a change in the attribute value of at least a configured minimum amount
- Reports are issued for the attribute periodically at a configured frequency

These mechanisms can operate at the same time. In this case, reports will be issued periodically and additional reports will be issued between periodic reports if triggered by changes in the attribute value.

If reports are triggered by frequent changes in the attribute value, they may add significantly to the network traffic. To manage this traffic, the production of reports for an attribute can be 'throttled'. This involves defining a minimum time-interval between consecutive reports for the attribute. If the attribute value changes within this time-interval since the last report, a new report will not be generated.

Note: If triggered reports are throttled, periodic reports will still be produced as scheduled.

Periodic reporting can be disabled, leaving only triggered reports to be automatically generated. Automatic reporting can also be disabled altogether (both mechanisms). For information on the configuration of automatic reporting, refer to Appendix B.3.

Parent topic:*Appendix B: Attribute reporting*

Appendix B.2: Default reporting For each cluster, the ZCL specification states that certain attributes must be reportable. These attributes are specified in the cluster descriptions in this manual. Reports on these attributes are optional and can be enabled on an individual basis using a 'reportable flag', as described in Appendix B.3.6. The attributes for which the flag is set will always be reported, defining a set of attributes for 'default reporting'.

Default reporting is a form of automatic reporting (see Appendix B.1) for the restricted set of attributes described above. It is configured on the cluster server as described in Appendix B.3.6. The attributes enabled for default reporting are also included in attribute reporting initiated by the server application though a call to the function **eZCL_ReportAllAttributes()**.

Parent topic:*Appendix B: Attribute reporting*

Appendix B.3: Configuring attribute reporting If attribute reporting is to be used by a cluster then the feature must be enabled at compile-time, as detailed in Appendix B.3.1. Then:

- If automatic attribute reporting is to be implemented then the reports must be configured as described in Appendix B.3.5.
- If default reporting is to be implemented then the reports must be configured as described in Appendix B.3.6.

The ZCL configuration for attribute reporting is described in Appendix B.3.7 for users who wish to modify this configuration.

B.3.1: Compile-time Options Attribute reporting is enabled at compile-time by setting the appropriate macros in **zcl_options.h**. The compile-time options relevant to the cluster server and client are listed separately below.

Parent topic: Appendix B.3: Configuring attribute reporting

B.3.2: Server Options

Generate Attribute Reports To enable a server to generate attribute reports according to configured reporting rules, add the following option:

```
#define ZCL_ATTRIBUTE_REPORTING_SERVER_SUPPORTED
```

Note: Attribute reporting does not need to be enabled with this macro if the reports are generated only via function calls.

Handle 'Configure Reporting' Commands To enable a server to handle 'configure reporting' commands and reply with 'configure reporting' responses, add the following option:

```
#define ZCL_CONFIGURE_ATTRIBUTE_REPORTING_SERVER_SUPPORTED
```

Handle 'Read Reporting Configuration' Commands To enable a server to handle 'read reporting configuration' commands and reply with 'read reporting configuration' responses, add the following option:

```
#define ZCL_READ_ATTRIBUTE_REPORTING_CONFIGURATION_SERVER_SUPPORTED
```

Number of Attribute Reports The number of reportable attributes can be set (to n) using the following line:

```
#define ZCL_NUMBER_OF_REPORTS   n
```

The default value is 10.

Number of String Attribute Reports The number of reportable string attributes can be set (to n) using the following line:

```
#define ZCL_NUMBER_OF_STRING_REPORTS   n
```

The default value is 0 (meaning that string attribute reports are disabled by default).

Maximum Size of Reportable String Attribute The maximum size, in bytes, of a string attribute that can be reported can be set (to n) using the following line:

```
#define ZCL_ATTRIBUTE_REPORT_STRING_MAXIMUM_SIZE   n
```

The default value is 32 bytes.

Minimum Attribute Reporting Interval The minimum time-interval, in seconds, between consecutive attribute reports can be set (to n) using the following line:

```
#define ZCL_SYSTEM_MIN_REPORT_INTERVAL   n
```

The default value is 1 second.

Maximum Attribute Reporting Interval The maximum time-interval, in seconds, between consecutive attribute reports can be set (to n) using the following line:

```
#define ZCL_SYSTEM_MAX_REPORT_INTERVAL   n
```

The default value is 61 seconds.

Parent topic: Appendix B.3: Configuring attribute reporting

B.3.3: Client Options

Receive Attribute Reports To enable a client to receive attribute reports from a server, add the following option:

```
#define ZCL_ATTRIBUTE_REPORTING_CLIENT_SUPPORTED
```

Send 'Configure Reporting' Commands To enable a client to send 'configure reporting' commands and handle the 'configure reporting' responses, add the following option:

```
#define ZCL_CONFIGURE_ATTRIBUTE_REPORTING_CLIENT_SUPPORTED
```

Send 'Read Reporting Configuration' Commands To enable a client to send 'read reporting configuration' commands and handle the 'read reporting configuration' responses, add the following option:

```
#define ZCL_READ_ATTRIBUTE_REPORTING_CONFIGURATION_CLIENT_SUPPORTED
```

Parent topic: Appendix B.3: Configuring attribute reporting

B.3.4: General (Server and Client) Options If attribute reporting is to report any attributes of the 'floating point' type, the following macro must also be enabled in **zcl_options.h** on both the server and client:

```
#define ZCL_ENABLE_FLOAT
```

This enables the use of the floating point library to calculate differences in attribute values. If this library is not already used by the application code, enabling it in this way increases the build size of the application by approximately 5 Kbytes.

Parent topic: Appendix B.3: Configuring attribute reporting

B.3.5: Configuring Automatic Attribute Reports (from Client) If automatic attribute reporting is to be employed between a cluster server and client, the reporting rules must be configured. These rules include the following parameters for each attribute:

- Time-interval between consecutive reports in periodic reporting
- Minimum time-interval between consecutive triggered attribute reports
- Minimum change in the attribute value that will trigger an attribute report

Note 1: Setting the periodic reporting time-interval to the special value of 0x0000 disables periodic reporting for the attribute. Setting this time-interval to the special value of 0xFFFF disables automatic reporting completely (periodic and triggered) for the attribute.

Note 2: Automatic attributes reports are normally produced on a timescale of seconds. However, reports generated on the change of an attribute value can be speeded up to occur on a timescale of milliseconds, as described in Appendix B.3.8.

Note 3: Before automatic reporting can be configured on an attribute, the 'reportable flag' must be set for the attribute on the cluster server using the function **eZCL_SetReportableFlag()**.

This configuration is conducted on the cluster server but is normally directed from a remote device via 'configure reporting' commands.

The configuration of automatic attribute reporting follows the process:

1. The client sends a 'configure reporting' command to the server.
2. The server receives and processes the command, configures the attribute reporting and generates a 'configure reporting' response, which it sends back to the requesting client.
3. The client receives the 'configure reporting' response and the ZCL generates events to indicate the status of the request to the client.

These steps are described separately below.

1. Sending a 'Configure Reporting' Command (from Client) The application on the cluster client device can configure attribute reporting for a set of attributes on the cluster server using the function **eZCL_SendConfigureReportingCommand()**. This function sends a 'configure reporting' command to the server.

In this function call, a pointer must be provided to an array of tsZCL_AttributeReportingConfigurationRecord structures, where each structure contains the configuration details for one attribute on which reporting is to be configured (see Section 6.1.5).

2. Receiving a 'Configure Reporting' Command (on Server) The server will automatically process an incoming 'configure reporting' command and perform the required configuration without assistance from the application. For each attribute (in the configuration request), the reporting configuration values are parsed, after which the ZCL generates an event of the type:

E_ZCL_CBET_REPORT_INDIVIDUAL_ATTRIBUTES_CONFIGURE

In the tsZCL_CallBackEvent structure (see Section 6.2) for this event:

- The uMessage field contains a structure of the type tsZCL_AttributeReportingConfigurationRecord (see Section 6.1.5).
- The eZCL_Status field indicates the outcome of parsing the configuration values for the attribute (success or failure)

Thus, the configuration of reporting for a set of attributes will result in a sequence of events of the above type, one for each attribute. The application should copy the contents of the tsZCL_AttributeReportingConfigurationRecord structure for each attribute to RAM (for information on storage format, refer to Appendix B.7.2).

Note that the tsZCL_AttributeReportingConfigurationRecord structure for an attribute contains the field u16MaximumReportingInterval which specifies a time-period for periodic reporting. Periodic reporting should not be too frequent, since a sleepy device must wake to send a report and frequent reports are be a significant drain on power resources. Therefore, the period for periodic reporting is not allowed to be set to a value less than sConfig.u16SystemMaximumReportingInterval in the ZCL configuration (see Appendix B.3.7). If a 'configure reporting' command attempts to set a smaller (non-zero) value, the ZCL discards the reporting configuration for this attribute and set the status for this attribute configuration to E_ZCL_CMDS_INVALID_VALUE in the 'configure reporting' response (see below).

Once attribute reporting has been configured (or not) for all the attributes (in the request), a single event is generated of the type:

E_ZCL_CBET_REPORT_ATTRIBUTES_CONFIGURE

Finally, the server generates a 'configure reporting' response and sends it back to the requesting client.

Note: The application and ZCL hold the attribute reporting configuration data in RAM. To preserve this data through episodes of power loss, the application should also save the data to NVM, as described in Appendix B.7.

3. Receiving a 'Configure Reporting' Response (on Client) A 'configure reporting' response from the cluster server contains an Attribute Status Record for each attribute that was included in the corresponding 'configure reporting' command. For each attribute in the response, the ZCL on the client generates an event of the type:

E_ZCL_CBET_REPORT_INDIVIDUAL_ATTRIBUTES_CONFIGURE_RESPONSE

In the tsZCL_CallBackEvent structure (see Section 6.2) for this event, the uMessage field contains a structure of the type tsZCL_AttributeReportingConfigurationResponse (see Section 6.1.6). In this structure:

- The eCommandStatus field indicates the status of the attribute reporting configuration for the attribute.
- The tsZCL_AttributeReportingConfigurationRecord structure (Section 6.1.5) contains other data but only the following fields are used:
  - u16AttributeEnum which identifies the attribute
  - u8DirectionIsReceived which should read 0x01 to indicate that reports of the attribute value are received by the client

Once the above event has been generated for each valid attribute in the response, a single E_ZCL_CBET_REPORT_ATTRIBUTES_CONFIGURE_RESPONSE event is generated to conclude the response.

Parent topic: Appendix B.3: Configuring attribute reporting

B.3.6: Configuring Default Reporting (on Server) Default reporting is a form of automatic reporting for a restricted set of attributes (see Appendix B.2). It is configured on the cluster server.

An individual attribute can be configured as potentially reportable through default reporting by setting the 'reportable flag' E_ZCL_AF_RP in either of the following ways:

- The flag can be incorporated in the line for the attribute in the tsZCL_AttributeDefinition structure for the cluster server. For example, in the following line of code, attribute reporting is enabled for the bOnOff attribute of the On/Off cluster:

```
E_CLD_ONOFF_ATTR_ID_ONOFF, (E_ZCL_AF_RD|E_ZCL_AF_SE|**E\_ZCL\_AF\_RP**), E_
↪ZCL_BOOL,
  (uint32)(&((tsCLD_OnOff*)(0))->bOnOff),0},
```

- The flag can be set by the server application by calling the function **eZCL_SetReportableFlag()**.

The reporting of these attributes can be configured by the server application by calling the function **eZCL_CreateLocalReport()** for each attribute. The configuration values are similar to those for automatic reporting, described in Appendix B.3.5. The reporting configuration is passed to the function in a sZCL_AttributeReportingConfigurationRecord structure. The application can then enable default reporting for reportable attributes using the function

vZCL_SetDefaultReporting(), which checks whether the E_ZCL_AF_RP flag has been set for each attribute and, if so, sets the 'default reporting flag' E_ZCL_ACF_RP.

Parent topic: Appendix B.3: Configuring attribute reporting

B.3.7: ZCL Configuration for Attribute Reporting This section describes aspects of ZCL configuration related to attribute reporting.

Note: The information in this section is only useful to developers who wish to adjust the standard ZCL configuration for attribute reporting.

Each attribute for which automatic reporting is enabled requires a tsZCL_ReportRecord structure. These structures are maintained internally by the ZCL and space for them is allocated on the ZCL heap. The heap is allocated using the **u32ZCL_Heap** macro - for example:

```
PRIVATE uint32 u32ZCL_Heap[
ZCL_HEAP_SIZE(ZCL_NUMBER_OF_ENDPOINTS,
ZCL_NUMBER_OF_TIMERS,
ZCL_NUMBER_OF_REPORTS)];
```

The number of reportable attributes and the maximum/minimum reporting intervals are passed into the internal eZCL_CreateZCL structure via the sConfig parameter - for example:

```
sConfig.u8NumberOfReports = ZCL_NUMBER_OF_REPORTS;
sConfig.u16SystemMinimumReportingInterval =
                    ZCL_SYSTEM_MIN_REPORT_INTERVAL;
sConfig.u16SystemMaximumReportingInterval =
                    ZCL_SYSTEM_MAX_REPORT_INTERVAL;
```

The above macros have default values that can be over-ridden in the application's **zcl_options.h** file, as indicated in Appendix B.3.1.

A server that supports automatic attribute reporting should have the 'reportable flag' E_ZCL_AF_RP set for any attributes that are reportable. While creating a cluster instance, the **vZCL_SetDefaultReporting()** function should be called, which will set the 'default reporting flag' E_ZCL_ACF_RP to enable default reporting for all the attributes that have the E_ZCL_AF_RP flag set. If a server receives a 'configure reporting' command for an attribute that does not have E_ZCL_ACF_RP flag set, it will return an error and not allow the attribute to be reported. This bit setting is also required for attribute reports generated through calls to the function **eZCL_ReportAllAttributes()**.

Attribute definitions will normally have the 'reportable flag' set only for the mandatory reportable attribute. The application on the server can set the E_ZCL_ACF_RP flag for those attributes on which reporting is not mandatory. This can be done using the function **eZCL_SetReportableFlag()**.

Parent topic: Appendix B.3: Configuring attribute reporting

B.3.8: Speeding Up Automatic Attribute Reports Automatic attribute reports (configured as described in Appendix B.3.5) that are produced on changes in attribute values can be speeded up to occur with millisecond resolution. Normally, these reports can occur on a timescale of seconds, as they are dependent on the E_ZCL_CBET_TIMER (one second) ticks for sampling. However, they can be made to occur on a timescale of milliseconds by providing E_ZCL_CBET_TIMER_MS (one millisecond) ticks.

In order to do this, the following code must be included in the application:

```
sCallBackEvent.eEventType = E_ZCL_CBET_TIMER_MS;
vZCL_EventHandler(&sCallBackEvent);
```

Note that the E_ZCL_CBET_TIMER ticks still need to be generated, as they are used by UTC time and by the ZCL report manager to keep track of time.

Parent topic: Appendix B.3: Configuring attribute reporting

Parent topic:*Appendix B: Attribute reporting*

Appendix B.4: Sending attribute reports If automatic attribute reporting has been configured between the cluster server and a client (as described in Appendix B.3), the reporting of the relevant attributes will begin immediately after configuration. Attribute reports are automatically generated:

- periodically with the configured time-interval between consecutive reports
- when the attribute value changes by at least the configured minimum amount

Automatic reporting normally employs both of the above mechanisms simultaneously but can be configured to operate without periodic reporting, if required.

If a periodic report becomes overdue, the event E_ZCL_CBET_REPORT_TIMEOUT is generated on the server.

The application on the server can also generate an attribute report, when needed, by calling one of the following functions:

- **eZCL_ReportAllAttributes()**, which sends an attribute report for all the reportable attributes
- **eZCL_ReportAttribute()**, which sends an attribute report for an individual reportable attribute

The above functions send an attribute report containing the current attribute value(s) to one or more clients specified in the function call. Only the standard attributes can be reported - this does not include manufacturer-specific attributes. Use of these functions for attribute reporting requires no special configuration on the server (but a recipient client will need attribute reporting to be enabled in its compile-time options).

Note: The event E_ZCL_CBET_REPORT_REQUEST is automatically generated on the server before sending an attribute report, allowing the application to update the attribute values in the shared structure, if required.

CAUTION:

The application must not rely on the above event as a prompt to update the shared structure when an attribute changes its value. The event is only generated when the change in attribute value is large enough for an attribute report to be produced. Smaller changes will not result in the event or a report.

Parent topic:*Appendix B: Attribute reporting*

Appendix B.5: Receiving attribute reports In order to receive and parse attribute reports from the cluster server, a client must have attribute reporting enabled in its compile-time options (see Appendix B.3.1).

When an attribute report is received from the server, events are generated and the ZCL software performs the following steps:

1. For each attribute in the attribute report, the ZCL generates an E_ZCL_CBET_REPORT_INDIVIDUAL_ATTRIBUTE message for the endpoint callback function, which may or may not take action on this message.

2. On completion of the parsing of the attribute response, the ZCL generates a single E_ZCL_CBET_REPORT_ATTRIBUTES message for the endpoint callback function, which may or may not take action on this message.

Note that:

- The E_ZCL_CBET_REPORT_INDIVIDUAL_ATTRIBUTE event has the same fields as the E_ZCL_CBET_READ_INDIVIDUAL_ATTRIBUTE_RESPONSE event. In the uMessage field of the tsZCL_CallBackEvent structure (see Section 6.2) for these events, the same structure is used, which is of the type tsZCL_IndividualAttributesResponse. However, the eAttributeStatus field is not updated for an attribute report (only for a 'read attributes' response).
- The E_ZCL_CBET_REPORT_ATTRIBUTES event has the same fields as the E_ZCL_CBET_READ_ATTRIBUTES_RESPONSE event.

Parent topic:*Appendix B: Attribute reporting*

Appendix B.6: Querying attribute reporting configuration Any authorised device in a ZigBee wireless network can obtain the attribute reporting configuration of a cluster server. Such a query follows the process below:

1. The cluster client sends a 'read reporting configuration' command to the server.
2. The server receives and processes the command, retrieves the required configuration information and generates a 'read reporting configuration' response, which it sends back to requesting client.
3. The client receives the 'read reporting configuration' response and the ZCL generates events to inform the application of the reporting configuration.

These steps are described separately below.

Sending a 'Read Reporting Configuration' Command (from Client) The application on the cluster client device can request the attribute reporting configuration on the server using **eZCL_SendConfigureReportingCommand()**. This function sends a 'read reporting configuration' command to the server.

In this function call, a tsZCL_AttributeReadReportingConfigurationRecord structure must be specified which indicates the required configuration information - this structure includes a pointer to an array of records, one per attribute for which reporting configuration information is needed (see Section 6.1.7).

Receiving a 'Read Reporting Configuration' Command (on Server) The server automatically processes an incoming 'read reporting configuration' command without assistance from the application. Callback events are not generated. However, the server generates a 'read reporting configuration' response and send it back to the requesting client.

Receiving a 'Read Reporting Configuration' Response (on Client) A 'read reporting configuration' response from the cluster server contains an Attribute Reporting Configuration Record for each attribute that was included in the corresponding 'read reporting configuration' command. For each attribute in the response, the ZCL on the client generates an event of the type:

E_ZCL_CBET_REPORT_READ_INDIVIDUAL_ATTRIBUTE_CONFIGURATION_RESPONSE

In the tsZCL_CallBackEvent structure (see Section 6.2) for this event, the uMessage field contains a structure of the type tsZCL_AttributeReportingConfigurationResponse (see Section 6.1.6) - this is the same structure as used in attribute reporting configuration, described in Appendix B.3.5.

In this structure:

- The eCommandStatus field indicates the status of the request.

- The tsZCL_AttributeReportingConfigurationRecord structure (see Section 6.1.5) includes:
  - u16AttributeEnum which identifies the attribute
  - other fields containing the attribute reporting configuration information

Once the above event has been generated for each valid attribute in the response, a single E_ZCL_CBET_REPORT_READ_ATTRIBUTE_CONFIGURATION_RESPONSE event is generated to conclude the response.

Parent topic:*Appendix B: Attribute reporting*

Appendix B.7: Storing an attribute reporting configuration During the configuration of automatic attribute reporting, described in Appendix B.3.5, the application on the server must store attribute reporting configuration data in RAM and, optionally, in Non-Volatile Memory (NVM). The storage of this data is described in the sub-sections below.

Persisting an attribute reporting configuration The attribute reporting configuration data is stored in RAM on the cluster server. To allow the server device to recover from an interruption of service involving a loss of power, this configuration data should also be saved in Non-Volatile Memory (NVM). In this case, the attribute reporting configuration data can be recovered from NVM during a 'cold start' of the device and automatic attribute reporting can resume without further configuration.

The storage of attribute reporting configuration data in NVM should be performed during the updates of this data on the server, described in Appendix B.3.5. When an E_ZCL_CBET_REPORT_INDIVIDUAL_ATTRIBUTES_CONFIGURE event is generated for an attribute, the contents of the incorporated structure tsZCL_AttributeReportingConfigurationRecord should be saved to NVM as well as to RAM (for information on storage format, refer to Appendix B.7.2). Data storage in NVM can be performed under application control using the Non-Volatile Memory Manager (NVM), described in the *Connectivity Framework Reference Manual*.

On a 'cold start' of the device, the application must retrieve the Attribute Reporting Configuration Record for each attribute from NVM and update the ZCL with the reporting configuration (this must be done after the ZCL has been initialized). To do this, the NVM can be used to retrieve the configuration record for an attribute and the function **eZCL_CreateLocalReport()** must then be called to register this data with the ZCL. This function must not be called for attributes that have not been configured for automatic attribute reporting (e.g. those for which the maximum reporting interval is set to REPORTING_MAXIMUM_TURNED_OFF).

Note: The maximum reporting interval in NVM must be set to REPORTING_MAXIMUM_TURNED_OFF (0xFFFF) during a factory reset in order to prevent reporting from being enabled for attributes for which reporting was not previously enabled.

Parent topic: Appendix B.7: Storing an attribute reporting configuration

Formatting an attribute reporting configuration record The format in which the server application stores attribute reporting configuration data in RAM and, optionally, in NVM is at the discretion of the application developer.

The most general method is to store this data in an array of structures, in which there is one array element for each attribute for which automatic reporting is implemented (the size of this array should correspond to the value of the compile-time option SE_NUMBER_OF_REPORTS - see Appendix B.3.1). The information stored for each attribute may include the relevant cluster ID and endpoint number, as well as details of the configured change that can result in an attribute report. However, this method of data storage may require significant memory space and may only be necessary for more complex applications.

Alternative storage formats for this data are possible which economize on the memory requirements. These methods are outlined below.

Reduced Data Storage A simple extension of the above general scheme uses application knowledge of the attributes being reported. In this case, certain static information about the reportable attributes is built into the compiled application and only the changeable information about these attributes is saved to an array in RAM (and NVM). In this way, the required memory space to store the attribute reporting configuration data is reduced.

An example of this method with five reportable attributes is given below.

```
#define SE_NUMBER_OF_REPORTS 5
typedef struct
  {
   uint16 u16Min;
   uint16 u16Max;
   tuZCL_AttributeReportable uChangeValue;
  } tsLocalStruct;
static tsLocalStruct asLocalConfigStruct[SE_NUMBER_OF_REPORTS];
typedef struct
 {
  uint16 u16AttEnum;
  teZCL_ZCLAttributeType eAttType;
 }tsLocalDefs;
static const tsLocalDefs asLocalDefs[SE_NUMBER_OF_REPORTS] = {
   {TPRC_MATCH_1,E_ZCL_UINT32},
   {TPRC_MATCH_6,E_ZCL_BMAP48},
   {TPRC_MATCH_7,E_ZCL_GINT56},
   {TPRC_MATCH_5,E_ZCL_UINT56},
   {TPRC_MATCH_3,E_ZCL_BOOL}
  };
```

In the above example:

- The fixed data (attribute identifier and type) is held in an array of tsLocalDefs structures, with one array element per attribute - this array is defined at compile-time and therefore does not need to be updated in RAM or persisted in NVM.
- The attribute reporting configuration data is held in an array of tsLocalStruct structures, with one array element per attribute - only this array needs to be updated in RAM and persisted in NVM, thus saving storage space.

Note that both arrays have SE_NUMBER_OF_REPORTS elements and there is a one-to-one correspondence between the elements of the two arrays - elements with the same number relate to the same attribute.

Minimized Data Storage It may be possible to optimize the format in which the attribute reporting configuration data is saved in order to suit the attributes reported. For example, if there are only two attributes to be reported, then it may be sufficient to store the attribute reporting configuration data in a single structure, like the following:

```
typedef struct
{
    uint16   u16MinimumReportingIntervalForAttA;
    uint16   u16MaximumReportingIntervalForAttA;
    zint32   u32AttAReportableChange;
    uint16   u16MinimumReportingIntervalForAttB;
    uint16   u16MaximumReportingIntervalForAttB;
        // Attribute B is a discrete type (for example, a bitmap), so does not have a reportable change
} tsZCL_PersistedAttributeReportingConfigurationRecord;
```

Parent topic: Appendix B.7: Storing an attribute reporting configuration

Parent topic:*Appendix B: Attribute reporting*

Appendix C: Extended attribute discovery 'Extended' attribute discovery is similar to the normal attribute discovery described in Section 2.3.4 except the accessibility of each attribute is additionally indicated as being 'read', 'write' or 'reportable'. The application coding details and compile-time options are different, and are described below.

Appendix C.1: Compile-time options If required, the extended attribute discovery feature must be explicitly enabled on the cluster server and client at compile-time by respectively including the following defines in the **zcl_options.h** files:

```
#define ZCL_ATTRIBUTE_DISCOVERY_EXTENDED_SERVER_SUPPORTED
#define ZCL_ATTRIBUTE_DISCOVERY_EXTENDED_CLIENT_SUPPORTED
```

Parent topic:*Appendix C: Extended attribute discovery*

Appendix C.2: Application coding The application on a cluster client can initiate an extended attribute discovery on the cluster server by calling the **eZCL_SendDiscoverAttributesExtendedRequest()** function, which sends a 'discover attributes extended' request to the server. This function allows a range of attributes to be searched for, defined by:

- The 'start' attribute in the range (the attribute identifier must be specified).
- The number of attributes in the range.

Initially, the start attribute should be set to the first attribute of the cluster. If the discovery request does not return all the attributes used on the cluster server, the above function should be called again with the start attribute set to the next 'undiscovered' attribute. Multiple function calls may be required to discover all of the attributes used on the server.

On receiving a discover attributes extended request, the server handles the request automatically (provided that extended attribute discovery has been enabled in the compile-time options - see above) and replies with a 'discover attributes extended' response containing the requested information.

The arrival of the response at the client results in the event E_ZCL_CBET_DISCOVER_INDIVIDUAL_ATTRIBUTE_EXTENDED_RESPONSE for each attribute reported in the response. Therefore, multiple events normally result from a single discover attributes extended request. This event contains details of the reported attribute in a tsZCL_AttributeDiscoveryExtendedResponse structure (see Section 6.1.11).

Following the event for the final attribute reported, the event E_ZCL_CBET_DISCOVER_ATTRIBUTES_EXTENDED_RESPONSE is generated to indicate that all attributes from the discover attributes extended response have been reported.

Parent topic:*Appendix C: Extended attribute discovery*

Appendix D: Custom endpoints A ZigBee device and its associated clusters can be registered on an endpoint using the relevant device registration function, from those listed and described in the *ZigBee Devices User Guide (JNUG3131)*. However, it is also possible to set up a custom endpoint which supports selected clusters (rather than a whole ZigBee device and all of its associated clusters). Custom endpoints are particularly useful when using multiple endpoints on a single node - for example, the first endpoint may support a complete ZigBee device (such as a Light Sensor) while one or more custom endpoints are used to support selected clusters.

Appendix D.1: Devices and Endpoints When using custom endpoints, it is important to note the difference between the following 'devices':

- **Physical device:** This is the physical entity which is the network node

- **Logical device:** This is a software entity which implements a specific set of functionality on the node, e.g. On/Off Switch device

A ZigBee network node may contain multiple endpoints, where one endpoint is used to represent the 'physical device' and other endpoints are used to support 'logical devices'. The following rules apply to cluster instances on endpoints:

- All cluster instances relating to a single 'logical device' must reside on a single endpoint.
- The Basic cluster relates to the 'physical device' rather than a 'logical device' instance. There can be only one Basic cluster server for the entire node, which can be implemented in either of the following ways:
  - A single cluster instance on a dedicated 'physical device' endpoint
  - A separate cluster instance on each 'logical device' endpoint, but each cluster instance must use the same tsZCL_ClusterInstance structure (and the same attribute values)

Parent topic:*Appendix D: Custom endpoints*

Appendix D.2: Cluster Creation Functions For each of the following clusters, a creation function is provided which creates an instance of the cluster on an endpoint:

- Basic: **eCLD_BasicCreateBasic()**
- Power Configuration: **eCLD_PowerConfigurationCreatePowerConfiguration()**
- Device Temperature Configuration: **eCLD_DeviceTemperatureConfigurationCreateDeviceTemperatur**
- Identify: **eCLD_IdentifyCreateIdentify()**
- Groups: **eCLD_GroupsCreateGroups()**
- Scenes: **eCLD_ScenesCreateScenes()**
- On/Off: **eCLD_OnOffCreateOnOff()**
- On/Off Switch Configuration: **eCLD_OOSCCreateOnOffSwitchConfig()**
- Level Control: **eCLD_LevelControlCreateLevelControl()**
- Alarms: **eCLD_AlarmsCreateAlarms()**
- Time: **eCLD_TimeCreateTime()**
- Analogue Input (Basic): **eCLD_AnalogInputBasicCreateAnalogInputBasic()**
- Analogue Output (Basic): **eCLD_AnalogOutputBasicCreateAnalogOutputBasic()**
- Binary Input (Basic): **eCLD_BinaryInputBasicCreateBinaryInputBasic()**
- Binary Output (Basic): **eCLD_BinaryOutputBasicCreateBinaryOutputBasic()**
- Multistate Input (Basic): **eCLD_MultistateInputBasicCreateMultistateInputBasic()**
- Multistate Output (Basic): **eCLD_MultistateOutputBasicCreateMultistateOutputBasic()**
- Poll Control: **eCLD_PollControlCreatePollControl()**
- Power Profile: **eCLD_PPCreatePowerProfile()**
- Diagnostics: **eCLD_DiagnosticsCreateDiagnostics()**
- Illuminance Measurement: **eCLD_IlluminanceMeasurementCreateIlluminanceMeasurement()**
- Illuminance Level Sensing: **eCLD_IlluminanceLevelSensingCreateIlluminanceLevelSensing()**
- Temperature Measurement: **eCLD_TemperatureMeasurementCreateTemperatureMeasurement()**
- Pressure Measurement: **eCLD_PressureMeasurementCreatePressureMeasurement()**
- Flow Measurement: **eCLD_FlowMeasurementCreateFlowMeasurement()**

- Relative Humidity Measurement: **eCLD_RelativeHumidityMeasurementCreateRelativeHumidityMeas**
- Occupancy Sensing: **eCLD_OccupancySensingCreateOccupancySensing()**
- Electrical Measurement: **eCLD_ElectricalMeasurementCreateElectricalMeasurement()**
- Colour Control: **eCLD_ColourControlCreateColourControl()**
- Ballast Configuration: **eCLD_BallastConfigurationCreateBallastConfiguration()**
- Thermostat: **eCLD_ThermostatCreateThermostat()**
- Thermostat User Interface Configuration: **eCLD_ThermostatUIConfigCreateThermostatUIConfig()**
- Door Lock: **eCLD_DoorLockCreateDoorLock()**
- IAS Zone: **eCLD_IASZoneCreateIASZone()**
- IAS Ancillary Control Equipment (ACE): **eCLD_IASACECreateIASACE()**
- IAS Warning Device (WD): **eCLD_IASWDCreateIASWD()**
- Price: **eSE_PriceCreate()**
- Demand-Response and Load Control (DRLC): **eSE_DRLCCreate()**
- Simple Metering: **eSE_SMCreate()**
- Commissioning:**eCLD_CommissioningClusterCreateCommissioning()**
- Touchlink Commissioning: **eCLD_ZllCommissionCreateCommission()**
- Appliance Control: **eCLD_ApplianceControlCreateApplianceControl()**
- Appliance Identification: **eCLD_ApplianceIdentificationCreateApplianceIdentification()**
- Appliance Events and Alerts: **eCLD_ApplianceEventsAndAlertsCreateApplianceEventsAndAlerts()**
- Appliance Statistics: **eCLD_ApplianceStatisticsCreateApplianceStatistics()**
- Over-The-Air (OTA) Upgrade: **eOTA_Create()**

More than one of the above functions can be called for the same endpoint in order to create multiple cluster instances on the endpoint.

Note: No more than one server instance and one client instance of a given cluster can be created on a single endpoint (e.g. one Identify cluster server and one Identify cluster client, but no further Identify cluster instances).

The creation functions for clusters are described in the corresponding chapters of this manual.

Parent topic:*Appendix D: Custom endpoints*

Appendix D.3: Custom Endpoint Set-up In order to set up a custom endpoint (supporting selected clusters), you must do the following in your application code:

1. Create a structure for the custom endpoint containing details of the cluster instances and attributes supported - see *Custom Endpoint Structure* below.
2. Initialise the fields of the tsZCL_EndPointDefinition structure for the endpoint.
3. Call the relevant cluster creation function(s) for the cluster(s) to be supported on the endpoint - see Appendix D.2.
4. Call the ZCL function **eZCL_Register()** for the endpoint.

Custom Endpoint Structure In your application code, to set up a custom endpoint you must create a structure containing details of the cluster instances and attributes to be supported on the endpoint. This structure must include the following:

- A definition of the custom endpoint through a tsZCL_EndPointDefinition structure - for example:
  - tsZCL_EndPointDefinition sEndPoint
- A structure containing a set of tsZCL_ClusterInstance structures for the supported cluster instances - for example:

```
typedef struct
{
    tsZCL_ClusterInstance sBasicServer;
    tsZCL_ClusterInstance sBasicClient;
    tsZCL_ClusterInstance sIdentifyServer;
    tsZCL_ClusterInstance sOnOffCluster;
    tsZCL_ClusterInstance sDoorLockCluster;
} tsHA_AppCustomDeviceClusterInstances
```

- For each cluster instance that is not shared with another endpoint, the following should be specified via the relevant tsZCL_ClusterInstance structure:
- Attribute definitions, if any - for example, the tsCLD_Basic structure for the Basic cluster
- Custom data structures, if any - for example, the tsIdentify_CustomStruct structure for the Identify cluster
- Memory for tables or any other resources, if required by the cluster creation function

Note: If a custom endpoint is to co-exist with a device endpoint, the endpoints can share the structures for the clusters that they have in common. Therefore, it is not necessary to define these cluster structures for the custom endpoint, since they already exist for the device endpoint.

Parent topic:*Appendix D: Custom endpoints*

Appendix E: Manufacturer-specific attributes and commands This appendix describes how a manufacturer can add their own custom attributes and commands to a cluster. Attributes and commands are covered in separate sections.

Appendix E.1: Adding Manufacturer-specific Attributes To add a manufacturer-specific attribute to a cluster:

1. Specify your manufacturer ID code in the Node descriptor. Do this in the ZPS Configuration Editor by clicking on **Node Descriptor** for the relevant node and editing the **Manufacturer Code** field on the **Properties** tab.
2. In the **zcl_options.h** file:

a) Define your manufacturer ID code - for example, for a code of 0x1234, add the line:

```
#define ZCL_MANUFACTURER_CODE 0x1234
```

b) Define the macro that enables the use of manufacturer-specific attributes for the cluster - this macro is cluster-specific but for the Electrical Measurement cluster, the relevant line is:

```
#define CLD_ELECTMEAS_ATTR_MAN_SPEC
```

c) Define an Attribute ID for the new attribute (you must not use a value already used by another attribute) - for example, to add an attribute with an ID of 0x0B00 to the Electrical Measurement cluster, the relevant line is:

```
#define E_CLD_ELECTMEAS_ATTR_ID_MAN_SPEC 0x0B00
```

3. Add the new attribute to the cluster structure in the cluster's header file - for example, the code below shows the attribute i16ManufacturerSpecific added to the Electrical Measurement cluster (in **ElectricalMeasurement.h**):

```
typedef struct
{
    zbmap32             u32MeasurementType;
#ifdef CLD_ELECTMEAS_ATTR_AC_FREQUENCY
    zuint16             u16ACFrequency;
#endif
#ifdef CLD_ELECTMEAS_ATTR_RMS_VOLTAGE
    zuint16             u16RMSVoltage;
#endif
#ifdef CLD_ELECTMEAS_ATTR_RMS_CURRENT
    zuint16             u16RMSCurrent;
#endif
#ifdef CLD_ELECTMEAS_ATTR_ACTIVE_POWER
    zint16              i16ActivePower;
#endif
#ifdef CLD_ELECTMEAS_ATTR_REACTIVE_POWER
    zint16              i16ReactivePower;
#endif
#ifdef CLD_ELECTMEAS_ATTR_APPARENT_POWER
    zuint16             u16ApparentPower;
#endif
#ifdef CLD_ELECTMEAS_ATTR_POWER_FACTOR
    zint8               i8PowerFactor;
#endif
**\#ifdef CLD\_ELECTMEAS\_ATTR\_MAN\_SPEC**
**    zint16             i16ManufacturerSpecific;**
**\#endif**
} tsCLD_ElectricalMeasurement;
```

4. Add the new attribute to the source (**.c**) file for the cluster, being careful to add the attribute in the correct sequential position - for example, the following code fragment shows the attribute i16ManufacturerSpecific added to the Electrical Measurement cluster (in **ElectricalMeasurement.c**):

```
const tsZCL_AttributeDefinition
asCLD_ElectricalMeasurementClusterAttributeDefinitions[] = {
/* ZigBee Cluster Library Version */
                :

#ifdef CLD_ELECTMEAS_ATTR_POWER_FACTOR
{E_CLD_ELECTMEAS_ATTR_ID_POWER_FACTOR,
E_ZCL_AF_RD,
E_ZCL_INT8,
(uint16)(&((tsCLD_ElectricalMeasurement*)(0))->i8PowerFactor),
0}, /* Optional */
#endif

/* Manufacturer-specific Read-only Attribute */
#ifdef CLD_ELECTMEAS_ATTR_MAN_SPEC
{E_CLD_ELECTMEAS_ATTR_ID_MAN_SPEC,
```

(continues on next page)

(continued from previous page)

```
(E_ZCL_AF_RD|E_ZCL_AF_MS),
E_ZCL_INT16,
(uint16)(&((tsCLD_ElectricalMeasurement*)(0))->i16ManufacturerSpecific),
0}, /* Optional */
#endif

/* Manufacturer-specific Read/Write Attribute */
#ifdef CLD_ELECTMEAS_ATTR_MAN_SPEC
{E_CLD_ELECTMEAS_ATTR_ID_MAN_SPEC,
(E_ZCL_AF_RD|E_ZCL_AF_WR|E_ZCL_AF_MS),
E_ZCL_INT16,
(uint16)(&((tsCLD_ElectricalMeasurement*)(0))->i16ManufacturerSpecific),
0}, /* Optional */
#endif
```

Within your application code, you can remotely read the value of the new attribute using the following function call:

```
eStatus = eZCL_SendReadAttributesRequest(1, 1, <Add cluster here>, FALSE,
&sSendAddress, &u8SequenceNumber, u8NumAtts, TRUE, HA_MANUFACTURER_CODE,
<Add your attribute to the list here>);
```

Parent topic:*Appendix E: Manufacturer-specific attributes and commands*

Appendix E.2: Adding Manufacturer-specific Commands To add a manufacturer-specific command to a cluster:

1. Ensure that a manufacturer ID code has been specified, as described in Appendix E.1.
2. In the **zcl_options.h** file, define a Command ID for the new command (you must not use a value already used by another command) - for example, to add a command with an ID of 0x20 to the Basic cluster, the relevant line is:

   ```
   #define E_CLD_BASIC_CMD_MANU_SPEC 0x20
   ```

3. In your application code, introduce a handling routine for the new command into the command handler function that is registered when the cluster instance is created - for example, in the case of the Basic cluster, this handler function is **eCLD_BasicCommandHandler()**, which is registered when the function **eCLD_BasicCreateBasic()** is called. Do this as follows:

   a) Define a handler routine specifically for the new command - for example, in the case of the Basic cluster, this function may be **eCLD_BasicHandleManuSpecCommand()** and has the prototype:

   ```
   ```

ZPS_tsAfEvent *pZPSevent, tsZCL_EndPointDefinition *psEndPointDefinition, tsZCL_ClusterInstance *psClusterInstance); “‘

```
b\) Add the Command ID and the above command-specific handler function into the registered command␣
↪handler function - for example, in the case of the Basic cluster, the code for **eCLD\_
↪BasicCommandHandler\(\)** would be modified as shown in the fragment below:

   PUBLIC teZCL_Status eCLD_BasicCommandHandler(
   ZPS_tsAfEvent *pZPSevent,
   tsZCL_EndPointDefinition *psEndPointDefinition,
   tsZCL_ClusterInstance *psClusterInstance)
{...
```

(continues on next page)

(continued from previous page)

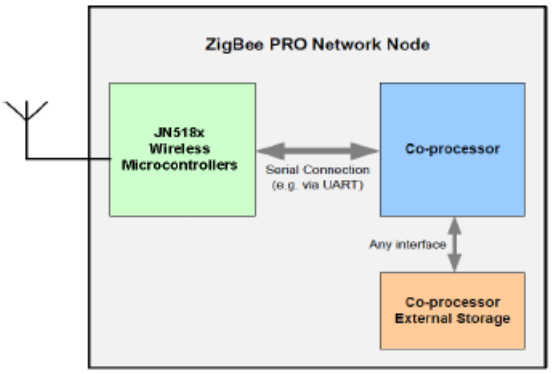
```
    // SERVER
switch(u8CommandIdentifier)
{
case(E_CLD_BASIC_CMD_RESET_TO_FACTORY_DEFAULTS):
{
eCLD_BasicHandleResetToFactoryDefaultsCommand(pZPSevent, psEndPointDefinition, psClusterInstance);
break;
}
case(E_CLD_BASIC_CMD_MANU_SPEC):
eCLD_BasicHandleManuSpecCommand(pZPSevent, psEndPointDefinition, psClusterInstance);
break;
default:
{
// unlock
eZCL_ReleaseMutex(psEndPointDefinition);
return(E_ZCL_FAIL);
break;
}
}
...
```

}

4. Add a command payload structure for the new command into the source (**.c**) file for the cluster - for␣
↪example:

typedef struct { uint8 u8PayloadField1; uint16 u16PayloadField2; uint16 u16PayloadField3; uint32 u32PayloadField4; }tsMS_ManuSpecCommand;

5. Add a function for sending the command to a remote node into the header (**.h**) and source (**.c**)␣
↪files for the cluster - for example, in the case of the Basic cluster, the function might be:



PUBLIC teZCL_Status eCLD_BasicCommandManuSpecSend(uint8 u8SourceEndpoint, uint8 u8DestinationEndpoint, tsZCL_Address *psDestinationAddress, tsMS_ManuSpecCommand *psManuSpecPayload, uint8 *pu8TransactionSequenceNumber) { teZCL_Status eZCL_Status; tsZCL_TxPayloadItem asPayloadDefinition[] = { {1, E_ZCL_UINT8, &psManuSpecPayload->u8PayloadField1}, {1, E_ZCL_UINT16, &psManuSpecPayload->u16PayloadField2}, {1, E_ZCL_UINT16, &psManuSpecPayload->u16PayloadField3}, {1, E_ZCL_UINT32, &psManuSpecPayload->u32PayloadField4} }; eZCL_Status = eZCL_CustomCommandSend(u8SourceEndpoint, u8DestinationEndpoint, psDestinationAddress, GENERAL_CLUSTER_ID_BASIC, TRUE, E_CLD_BASIC_CMD_MANU_SPEC, pu8TransactionSe asPayloadDefinition, TRUE, HA_MANUFACTURER_CODE, sizeof(asPayloadDefinition) / sizeof(tsZCL_TxPayloadItem)); return eZCL_Status; }

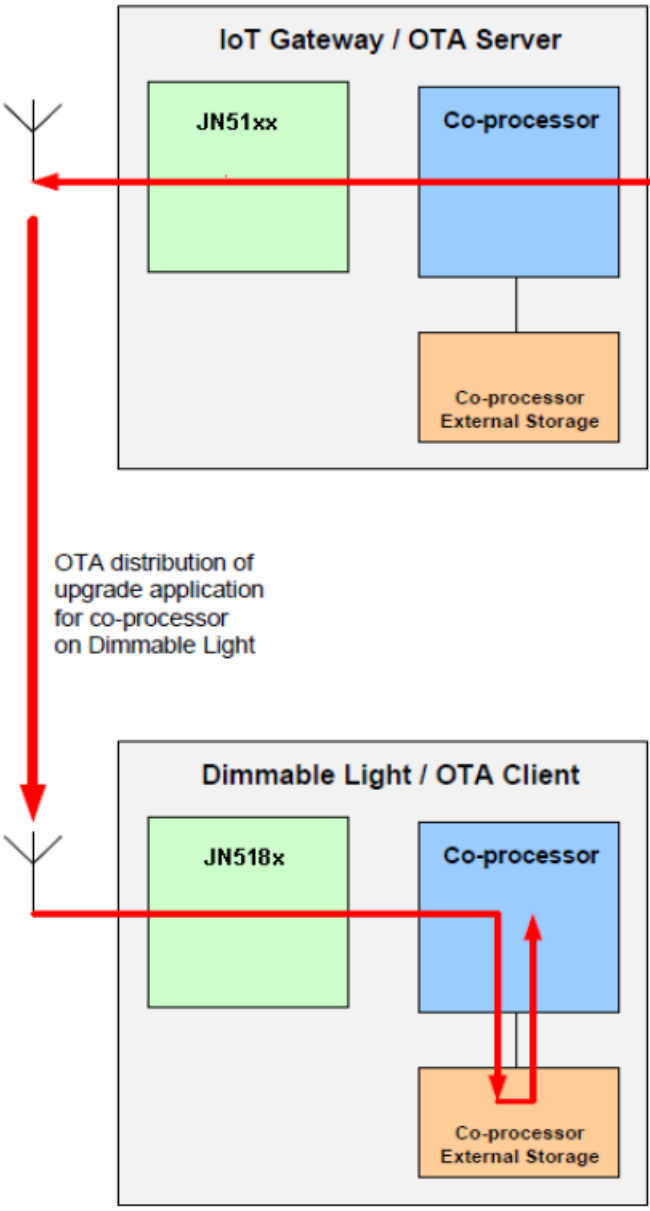
↪manufacturer-specific_attributes_and_commands.md)

Appendix F: OTA extension for dual-processor nodes This appendix describes use of the Over-the-Air (OTA) Upgrade cluster (introduced in *Chapter 49*) for a ZigBee PRO network consisting of dual-processor nodes that each contain a JN518x, K32W041, K32W061, MCXW71, or

MCXW72 wireless microcontroller and a co-processor.

The co-processor is connected to the device via a serial interface and may have its own external storage device, as depicted in the figure below.



Dual-Processor Node | |

The OTA Upgrade cluster may be used to upgrade the application which runs on the co-processor as well as the application which runs on the JN518x, K32W041, K32W061, MCXW71, or MCXW72 device. In this case, the OTA upgrade process is outlined below.

1. On the OTA server node (which is typically also the ZigBee Co-ordinator), the co-processor receives a new software image for the ZigBee PRO network.
2. The co-processor on the OTA server node saves the received software image in its own storage device.
3. The OTA Upgrade cluster server running on the JN518x, K32W041, or K32W061 device distributes the software update over-the-air to the appropriate ZigBee PRO network nodes, as described in Section 49.4.
4. On a target node, the OTA Upgrade cluster client running on the JN518x/K32W041/61 microcontroller either stores the received software image in its own Flash memory device or passes it to the co-processor for storage in the co-processor's own storage device, depending on whether the application in the update is destined for the device or the co-processor.
5. The OTA Upgrade cluster client running on the JN518x, K32W041, or K32W061 device then either performs the upgrade of the application running on itself or signals to the co-processor to initiate an upgrade of its own application, as appropriate.

The above process is illustrated in the figure below for the case of a ZigBee 3.0 network in which the co-processor application on a Dimmable Light (OTA client) is updated from an external source via an 'Internet of Things' (IoT) Gateway (OTA server) and the image is stored in the target co-processor's own storage device.

Example of OTA Upgrade of Co-processor Application |

Appendix F.1: Application Upgrades for Different Target Processors In a ZigBee PRO network containing dual-processor nodes (with a JN518x, K32W041, or K32W061 Wireless microcontroller and a co-processor), an application upgrade can be targeted at any of the following processors:

- OTA server node processors:
  - Wireless Microcontroller (JN518x, K32W041, or K32W061)
  - Co-processor
- OTA client node processors:
  - Wireless Microcontroller (JN518x, K32W041, or K32W061)
  - Co-processor

Only application upgrades for the OTA client node processors need the new software image to be distributed over-the-air.

The following table describes the roles of the different processors (and their associated memory devices) during the different application upgrades.

* If insufficient space in Flash memory, image may be stored in co-processor storage - see Appendix F.2

The case of the co-processor on the OTA server node updating its own application is not described any further in this manual, as this upgrade mechanism is specific to the co-processor. The other three application upgrade scenarios are described in Appendix F.2.

Parent topic:*Appendix F: OTA extension for dual-processor nodes*

Appendix F.2: Storing Upgrade Images in Co-processor Storage on Server When the co-processor on the OTA server node receives a new OTA upgrade image from an external source (such as a utility company), if the image is not for the co-processor itself then it is normally passed to the Wireless Microcontroller device for storage in the attached Flash memory device. However, if there is insufficient storage space in Flash memory then the new image will need to be stored in the storage device of the co-processor:

- When the co-processor application notifies the Wireless Microcontroller application of the arrival of a new image, the Wireless Microcontroller application must check whether there is sufficient Flash memory space for the image.
- If there is insufficient Flash memory space, the Wireless Microcontroller application must inform the co-processor that it should store the image in its own storage device.

The maximum number of images that can be stored in the co-processor's storage device on the OTA server node must be specified as a compile-time option in the **zcl_options.h** file through the macro OTA_MAX_CO_PROCESSOR_IMAGES.

The OTA Upgrade cluster server will require knowledge of any OTA upgrade images stored in the co-processor's storage device - the cluster server must be able to advertise the availability of the image to cluster clients and be able to process requests for the image from clients. To facilitate this role, once the image has been saved, the co-processor must provide the OTA image header information to the Wireless Microcontroller application. The latter application can then register this header information with the cluster server by calling the function **eOTA_NewImageLoaded()**.

When an Image Block Request from a cluster client is received by the cluster server for an image stored in the co-processor's storage device, the event E_CLD_OTA_INTERNAL_COMMAND_CO_PRECOSSOR_IMAGE_BLOCK_REQUEST is generated on the Wireless Microcontroller. After requesting and receiving the required image block from the co-processor, the application must send the block to the relevant client by calling the function **eOTA_ServerImageBlockResponse()** to issue an Image Block Response.

Parent topic:*Appendix F: OTA extension for dual-processor nodes*

Appendix F.3: Use of Image Indices Each OTA upgrade image that is stored in non-volatile memory in a node is identified by an index number. This image index number is actually associated with the memory space allocated to a single image, rather than with a particular image. For example, the image index number 1 may correspond to sectors 3 and 4 of the Flash memory attached to the device.

Note: In the case of external Flash memory, an image index number is linked with the start sector of the memory allocated to a single image when the function **eOTA_AllocateEndpointOTASpace()** is called.

- The maximum number of images that can be stored in the external Flash memory is set at compile-time by defining a value for OTA_MAX_IMAGES_PER_ENDPOINT in the **zcl_options.h** file. The minimum value that can be used is 1, since the active image is held in the internal Flash memory and does not need to be included.

- Since the image indices are numbered from zero, they can take values in the range:
  - 0 to (OTA_MAX_IMAGES_PER_ENDPOINT - 1)

In the case of a dual-processor node, OTA upgrade images may also be stored in the co-processor's external storage device. The maximum number images that can be stored in this device is set at compile-time by defining a value for OTA_MAX_CO_PROCESSOR_IMAGES in the **zcl_options.h** file.

- The maximum number of images that can be stored across the two storage devices is:
  - OTA_MAX_IMAGES_PER_ENDPOINT + OTA_MAX_CO_PROCESSOR_IMAGES
- The image indices can take values in the range:
  - 0 to (OTA_MAX_IMAGES_PER_ENDPOINT + OTA_MAX_CO_PROCESSOR_IMAGES - 1)
- The indices of the images stored in the external Flash memory still take values in the range:
  - 0 to (OTA_MAX_IMAGES_PER_ENDPOINT - 1)
- The indices of the images stored in co-processor external storage take values in the range:
  - OTA_MAX_IMAGES_PER_ENDPOINT to (OTA_MAX_IMAGES_PER_ENDPOINT + OTA_MAX_CO_PROCESSOR_IMAGES - 1)

Document ID	Release date	Description
3.2	11 March 2025	Added support for RW612 devices
3.1	24 January 2025	Added support for MCXW71 and MCXW72 devices
3.0	1 March 2023	- Added support for K32W1 device

- Updated to latest NXP Documentation template

| |2.0|18 November 2019|Updated for JN518x and K32W041/K32W061| |1.0|20 June 2018|First release|

The following documents provide details on how to demonstrate the capabilities of the NXP Wireless SoC when used as a Zigbee Coprocessor together with a Zigbee application running on the iMX8 (or x86) platform under Linux.

ZigBee NCP Host Coordinator Example

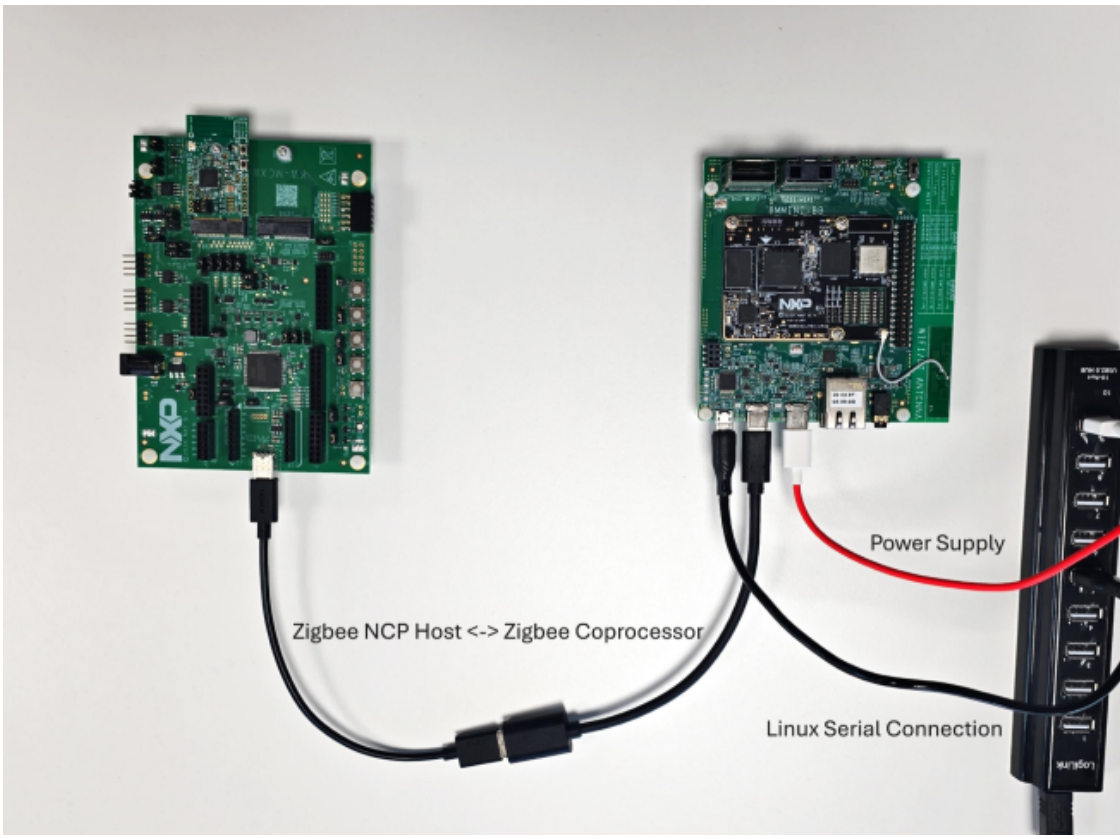
1. General description

List of supported NXP Wireless SoC to act as coprocessor:

- MCXW71-EVK
- FRDM-MCXW71
- K32W061

2. Required Hardware

- 1 x iMX8MMINI-EVK board or 1 x iMX8ULP-EVK board running Linux - Host
- 1 x MCXW71-EVK board or 1 x K32W061 DK6 board or 1 x FRDM-MCXW71 board – Zigbee NCP coprocessor
- 1 x K32W061 DK6 board - Zigbee End Device



2.1. iMX8 board configuration

2.2. Zigbee NCP coprocessor board configuration

2.2.1 MCXW71-EVK/FRDM-MCXW71 board configuration

2.2.2 K32W061 DK6 board configuration

2.3. K32W061 DK6 board configuration (ZED RX ON)

2.4. Setup Example

3. Building

Environment Setup The NCP Host offers toolchain files that can be used to compile and cross compile the applications. They are available at ZIGBEE_BASE/platform/NCP_HOST/cmake/toolchains and should be provided to cmake -DCMAKE_TOOLCHAIN_FILE command line argument:

- x86_64-linux-gnu.cmake - toolchain file for x86 compile
- arm-linux - toolchain file for imx8 cross-compile

The armgcc toolchain was obtained from official Arm GNU Toolchain website and by default the toolchain file relies on this particular configuration. User can change through environment variables and cmake arguments the default behavior.

- ARMGCC_DIR - path to installed toolchain
- TOOLCHAIN_NAME - toolchain name

The Mbedtls package is required for the encryption/decryption capabilities needed to obtain a secured Serial Link. There are three options to obtain the mbedlts library, options configurable through cmake command line arguments:

- CONFIG_MBEDTLS_SOURCE=SDK - Mbedtls package is obtained from MCUXPRESSO SDK
- CONFIG_MBEDTLS_SOURCE=GIT - Mbedtls package is retrieved from git official repository
- CONFIG_MBEDTLS_SOURCE=SYSTEM - Mbedtls package is used as a preinstalled package

Examples for cross-compile:

- cmake .. -DCMAKE_TOOLCHAIN_FILE=$PWD/../../../../platform/NCP_HOST/cmake/toolchains/arm-linux.cmake -DCONFIG_MBEDTLS_SOURCE=SYSTEM - Cross-compile for imx8 with mbedtls as a preinstalled package. The toolchain file provided detects that machine type is imx8
- cmake .. -DCMAKE_TOOLCHAIN_FILE=$PWD/../../../../platform/NCP_HOST/cmake/toolchains/arm-linux.cmake -DTOOLCHAIN_NAME=aarch64-linux-gnu - Cross-compile for imx8 with toolchain available for Ubuntu 22.04

3.1. iMX8 platform

```
>$ cd out ; cmake .. -DMACHINE_TYPE=imx8
-- The C compiler identification is GNU 13.2.1

4. Running the application

4.1. Starting the coordinator

Command to display default latency timer for ttyUSB interface: cat /sys/bus/usb-serial/devices/ttyUSB0/latency_timer

Command to modify default latency timer for ttyUSB interface: echo 1 | sudo tee /sys/bus/usb-serial/devices/ttyUSB0/latency_timer.

Example to start the Zigbee NCP Coordinator:

```
>root@ubuntu:~ ./zb_coord_linux /dev/ttyACM0
[0] Created NCP Host Task with pid 653686
[0] MAIN
[0] ZQ: Initialised a queue: Handle=565ec8c4 Length=30 ItemSize=96
[0] ZQ: Initialised a queue: Handle=565ece50 Length=30 ItemSize=4
[0] ZQ: Initialised a queue: Handle=565ece68 Length=35 ItemSize=4
[0] ZQ: Initialised a queue: Handle=565ece38 Length=3 ItemSize=48
[0] ZQ: Initialised a queue: Handle=565f3700 Length=20 ItemSize=4
[0] ZQ: Initialised a queue: Handle=565f3728 Length=38 ItemSize=4
[0] serial Link initialised
[0] eOTA_NewImageLoaded status = 1
[2] New max process gap 1
[2] Pkt Type 0010 Set New Max Response Time 2
[212] New max process gap 210
[226] Pkt Type 0012 Set New Max Response Time 13
[1178] Recovered Application State 0 On Network 0
>
```

4.2. Forming the network

```
[3259] Form
[3259] APP-EVT: Event 8, NodeState=0
[3267] BDB: Forming Centralized Nwk
[3285] Pkt Type 0024 Set New Max Response Time 18
[3285] APP-EVT: Request Nwk Formation 00
[3805] Nwk formation took 538 MS
[3805] BDB: APP_vGenCallback [0 4]
ZPS_vSetTCLockDownOverride
[3805] APP-BDB: NwkFormation Success
[3805] APP-ZDO: Network started Channel = 12
```

4.3. Steer the network

```
[5879] Steer
[5879] APP-EVT: Event 6, NodeState=10
[5888] APP-BDB: NwkSteering Success
[5888] APP-EVT: Request Nwk Steering 00
[6765] BDB: APP_vGenCallback [0 9]
[6765] APP-ZDO: New Node 0be0 Has Joined

```

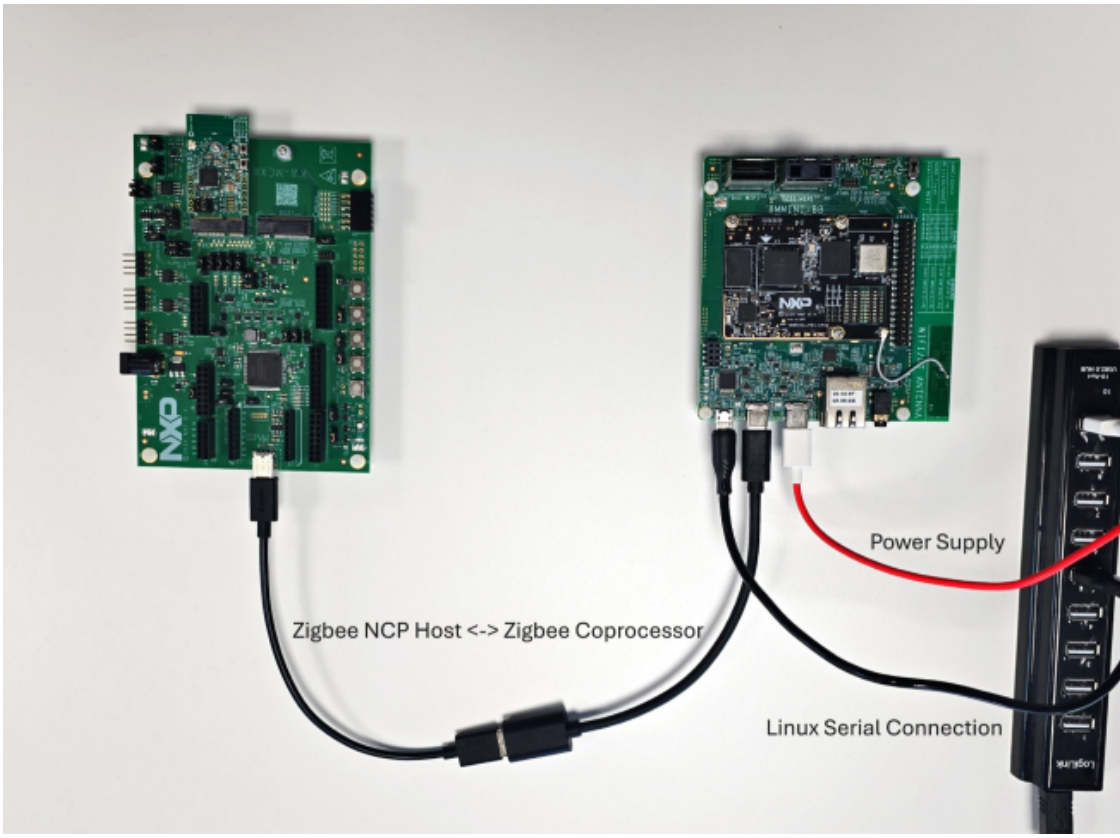
ZigBee NCP Host Router Example

1. General description List of supported NXP Wireless SoC to act as coprocessor:

- MCXW71-EVK
- FRDM-MCXW71
- K32W061

2. Required Hardware

- 1 x iMX8MMINI-EVK board or 1 x iMX8ULP-EVK board running Linux - Host
- 1 x MCXW71-EVK board or 1 x K32W061 DK6 board or 1 x FRDM-MCXW71 board – Zigbee NCP coprocessor
- 1 x MCXW71-EVK board or 1 x K32W061 DK6 board or 1 x FRDM-MCXW71 board - Zigbee Coordinator



2.1. iMX8 board configuration

2.2. Zigbee NCP coprocessor board configuration

2.2.1 MCXW71-EVK/FRDM-MCXW71 board configuration

2.2.2 K32W061 DK6 board configuration

2.3. K32W061 DK6/ MCXW71-EVK/ FRDM-MCXW71 board configuration (Coordinator)

2.4. Setup Example

3. Building

Environment Setup The NCP Host offers toolchain files that can be used to compile and cross compile the applications. They are available at ZIGBEE_BASE/platform/NCP_HOST/cmake/toolchains and should be provided to cmake -DCMAKE_TOOLCHAIN_FILE command line argument:

- x86_64-linux-gnu.cmake - toolchain file for x86 compile
- arm-linux - toolchain file for imx8 cross-compile

The armgcc toolchain was obtained from official Arm GNU Toolchain website and by default the toolchain file relies on this particular configuration. User can change through environment variables and cmake arguments the default behavior.

- ARMGCC_DIR - path to installed toolchain
- TOOLCHAIN_NAME - toolchain name

The Mbedtls package is required for the encryption/decryption capabilities needed to obtain a secured Serial Link. There are three options to obtain the mbedlts library, options configurable through cmake command line arguments:

- CONFIG_MBEDTLS_SOURCE=SDK - Mbedtls package is obtained from MCUXPRESSO SDK
- CONFIG_MBEDTLS_SOURCE=GIT - Mbedtls package is retrieved from git official repository
- CONFIG_MBEDTLS_SOURCE=SYSTEM - Mbedtls package is used as a preinstalled package

Examples for cross-compile:

- cmake .. -DCMAKE_TOOLCHAIN_FILE=$PWD/../../../../platform/NCP_HOST/cmake/toolchains/arm-linux.cmake -DCONFIG_MBEDTLS_SOURCE=SYSTEM - Cross-compile for imx8 with mbedtls as a preinstalled package. The toolchain file provided detects that machine type is imx8
- cmake .. -DCMAKE_TOOLCHAIN_FILE=$PWD/../../../../platform/NCP_HOST/cmake/toolchains/arm-linux.cmake -DTOOLCHAIN_NAME=aarch64-linux-gnu - Cross-compile for imx8 with toolchain available for Ubuntu 22.04

3.1. iMX8 platform

```
>$ cd out ; cmake .. -DMACHINE_TYPE=imx8

4. Running the application

4.1. Forming the network On the Zigbee Coordinator, issue the form command on the serial port:

```
eOTA_NewImageLoaded status = 1Recovered Application State 0 On Network 0
form
APP-EVT: Event 8, NodeState=0
APP-EVT: Request Nwk Formation 00
APP-BDB: NwkFormation Success
APP-ZDO: Network started Channel = 12
```

4.2. Steering the network On the Zigbee Coordinator, issue the steer command on the serial port:

```
steer
APP-EVT: Event 6, NodeState=10
APP-BDB: NwkSteering Success
APP-EVT: Request Nwk Steering 00
```

4.3. Starting the Router Command to display default latency timer for ttyUSB interface: `cat /sys/bus/usb-serial/devices/ttyUSB0/latency_timer`

Command to modify default latency timer for ttyUSB interface: `echo 1 | sudo tee /sys/bus/usb-serial/devices/ttyUSB0/latency_timer`.

Example to start the Zigbee NCP Router:

```
>root@ubuntu:~ ./zb_router_linux /dev/ttyACM0
[0] Created NCP Host Task with pid 451116
[0] MAIN
[0] ZQ: Initialised a queue: Handle=ad045b60 Length=30 ItemSize=104
[0] ZQ: Initialised a queue: Handle=ad0460c0 Length=30 ItemSize=8
[0] ZQ: Initialised a queue: Handle=ad046100 Length=35 ItemSize=8
```

(continues on next page)

(continued from previous page)

```
[0] ZQ: Initialised a queue: Handle=ad046080 Length=2 ItemSize=64
[0] ZQ: Initialised a queue: Handle=ad04cac0 Length=20 ItemSize=8
[0] ZQ: Initialised a queue: Handle=ad04cb10 Length=38 ItemSize=8
[0] serial Link initialised
[0] eStatusReportReload = 1
[211] New max process gap 1
[214] New max process gap 2
[228] Pkt Type 003a Set New Max Response Time 16
[276] Pkt Type 9094 Set New Max Response Time 17
[819] Pkt Type 0012 Set New Max Response Time 47
[1029] New max process gap 210
[1379] Start Up State 0 On Network 0
>
```

4.4. Joining the network

Once the network is created by the Zigbee Coordinator, the Zigbee NCP Router should join without any additional commands.

```
[5777] BDB: vNsTryNwkJoin - try 0 index 0 of 1 Nwks
[5792] BDB: Try To join 0060377791d75e0f on Ch 21
[5825] APP-ZDO: Discovery Complete 00
[6463] Nwk formation/joining took 6463 MS
...
[7104] Nwk Join Success
[7135] APP: NwkSteering Success
[7135] APP: BDB_EVENT_REJOIN_SUCCESS
[7135] APP-ZDO: Trust Center Status 00
```

4.5. Find and Bind

```
find
APP-EVT: Event 7, NodeState=10
APP-EVT: Find and Bind initiate 00
```

```
[43121] Find
[43121] ZPR: App event 7, NodeState=10
[43129] APP: NwkSteering Success
[43129] APP: BDB_EVENT_REJOIN_SUCCESS
[43593] Update Id 0003
[44617] Update Id 0003
[44617] Update Id 0003
...
```

```
APP-BDB: F&B Simple Desc response From cd7f Profle 0104 Device 0000 Ep 1 Version 0
APP-BDB: Check For Binding Cluster 0006
APP-BDB: Bind Created for cluster 0006
Remote Bind Dst addr cd7f, Ieee Dst Addr 0060377791d75e0f Ieee Src 00158d00031f1224
Sending a remote bind request Status =0
APP-BDB: Bind Created for target EndPt 1
```

```
[45472] BDB: APP_vGenCallback [0 17]
[45472] APP-ZDO: Zdo Bind event
```

4.6. Toggle commands

```
ZCL Attribute Report: Cluster 0006 Attribute 0000 Value 0
ZCL Attribute Report: Cluster 0006 Attribute 0000 Value 0
...
```

```
...
ZCL Attribute Report: Cluster 0006 Attribute 0000 Value 0
toggle
APP-EVT: Event 5, NodeState=10
APP-EVT: Send Toggle Cmd
ZCL Attribute Report: Cluster 0006 Attribute 0000 Value 1
ZCL Attribute Report: Cluster 0006 Attribute 0000 Value 1
```

The following user guides explain how to use Bluetooth LE - Zigbee dynamic mode applications in the context of a Zigbee commissioning over Bluetooth LE use case.

Zigbee coordinator BLE wireless UART demo example This application is provided in the context of demonstrating the Zigbee commissioning over Bluetooth LE and is part of the wireless examples for Zigbee.

Depending on the underlying board, the application is available in two flavours:

- zigbee_coordinator_ble_uart: the zigbee application part is based on the Zigbee Coordinator example and the Bluetooth LE application part is based on the Wireless UART peripheral demo. Targeted boards: MCX-W71-EVK, FRDM-MCXW71, MCX-W72-EVK, FRDM-MCXW72.
- zigbee_coordinator_ble_wu: the zigbee application is based on the Zigbee Coordinator example and the Bluetooth LE application part is based on the EdgeFast Wireless UART demo. Targeted boards: RD-RW612-BGA, FRDM-RW612.

The Narrow Band Unit (NBU) firmware for this application is included in the SDK folder and should be updated based on targeted board. The NBU firmware to be written for Bluetooth LE - Zigbee dynamic mode applications is the same image used for Zigbee example applications.

After reboot, the device running the application is ready to receive commands over Bluetooth LE through the Wireless UART profile. The communication over Bluetooth LE between the application can be intermediated by a mobile application.

To test the application the IoT Toolbox application can be used which is available for both Android and iOS. IoT Toolbox provides an application called ZigBee shell that can be used to send CLI commands over Bluetooth LE through the Wireless UART profile.

The functionality of the Coordinator application is described as follows:

- The Coordinator is responsible for initially forming the network. It also manages other devices that can join the network via the Trust center functionality. It also distributes security materials to those devices that are allowed to join. The Coordinator supports the mandatory clusters and features of the Base Device as defined in the ZigBee Base Device Behavior Specification.
- For demonstrating the “Finding and Binding” functionality, the Coordinator also supports the On/Off Cluster as a client.
- The commands should be sent over Bluetooth LE through the Wireless UART profile. Refer to the *Available CLI commands* chapter for more information on the available commands.

Forming a network A network can be formed from a factory-new Coordinator by sending the zigbee_create_network command. The Coordinator then forms a network. Optionnaly, A ZigBee packet sniffer (running separately on a USB Dongle) might be used to validate if the network is correctly formed. The periodic “link status” messages must be present on the operational channel.

Allowing other devices to join the network Commissioning description and step by step procedure are provided in: commissioning.md

Operating the device The operational functionality of this device in this demonstration is provided by the On/Off cluster. Before being able to send On/Off toggle commands to other devices, the Coordinator must start a Find and Bind as an initiator, this is done by using the zigbee_find command. The other devices must start a Find and Bind procedure as a target. Once bound, the Coordinator can send On/Off toggle commands using zigbee_toggle command to the bound devices.

Rejoining a network As a Coordinator, when this device is restarted in a state that is not factory-new, it resumes operation in its previous state. All applications, bindings, groups, and network parameters are preserved in non-volatile memory.

Performing a factory reset The Coordinator can be returned to its factory-new state, which erases all persistent data except the outgoing network frame counter. To perform a factory reset, send the zigbee_factoryreset command over BLE Wireless UART profile.

LED indication table

LED1	LED2	NOTES
OFF	OFF	The device is not on the network
OFF	ON	The device is active
OFF	Blinking every 1s	Find and Bind active

Available CLI commands

Command	Description
zigbee_factoryrese	Resets the device to its factory state
zigbee_get_networ	Returns the network status NETWORK_CREATED or NETWORK_NOT_CREATED
zigbee_get_networ	Returns the network info, Network Info would be serialized in the TLV format if created or NETWORK_NOT_CREATED (if the network is not formed)
zigbee_create_net	Allows to create a zigbee network, NETWORK_ALREADY_CREATED will be retured if the network is already formed
zigbee_find	Start Find & Bind as an initiator, make sure to trigger Find & Bind on a TARGET device
zigbee_toggle	Sends on\off toggle command to bound devices

OTA The Coordinator example supports the OTA Server cluster. As many factors depend on the platform used, please check the platform specific documentation:

- *RW612*

Zigbee Router BLE wireless UART demo example This application is provided in the context of demonstrating the Zigbee commissioning over Bluetooth LE and is part of the wireless examples for Zigbee.

Depending on the underlying board, the application is available in two flavours:

- zigbee_router_ble_uart: the zigbee application part is based on the Zigbee Router example and the Bluetooth LE application part is based on the Wireless UART peripheral demo. Targeted boards: MCX-W71-EVK, FRDM-MCXW71, MCX-W72-EVK, FRDM-MCXW72.

- zigbee_router_ble_wu: the zigbee application is based on the Zigbee Router example and the Bluetooth LE application part is based on the EdgeFast Wireless UART demo. Targeted boards: RD-RW612-BGA, FRDM-RW612.

The Narrow Band Unit (NBU) firmware for this application is included in the SDK folder and should be updated based on targeted board. The NBU firmware to be written for Bluetooth LE - Zigbee dynamic mode applications is the same image used for Zigbee example applications.

After reboot, the device running the application is ready to receive commands over Bluetooth LE through the Wireless UART profile. The communication over Bluetooth LE between the application can be intermediated by a mobile application.

To test the application the IoT Toolbox application can be used which is available for both Android and iOS. IoT Toolbox provides an application called ZigBee shell that can be used to send CLI commands over Bluetooth LE through the Wireless UART profile.

The Zigbee Router demo example demonstrates the Router device type and the "Find and Binding" functionality. To do so, it supports the On/Off Cluster as a server.

A CLI similar to the Coordinator's one is provided. Refer to the *Available CLI commands* chapter for more information on the available commands.

Joining a network The commissioning procedure to join a network is described in: commissioning.md

Operating the device The operational functionality of this device in this demonstration is provided by the On/Off cluster. Since the device supports the On/Off cluster server, its operation is passive, and it responds to commands sent by bound devices. It responds to an OnOff Toggle command from a bound controller device by toggling the LED1 on the board if there's one available.

Rejoining a network As a Router, when this device is restarted in a state, which is not factory-new, it resumes operation in its previous state. All application, binding, group, and network parameters are preserved within the non-volatile memory of the device.

Performing a factory reset The Router can be returned to its factory-new state (erasing all persistent data except the outgoing network frame counter) by sending zigbee_factoryreset command over BLE Wireless UART profile.

The Router then broadcasts a Leave Indication on the old network. It also deletes all persistent data (except the outgoing network frame counter) and performs a software reset. There are two supported over-the-air commands for removing a device from the network. These commands are listed below:

- Network Leave Request without rejoin
- ZDO Management Network Leave Request without rejoin

Binding devices The Router supports the On/Off cluster as a server and implement the "Finding and Binding" process as a target. To trigger "Finding and Binding" as a target, perform the following step:

1. Press the USER button on the board of the target device.
2. Start "Finding and Binding" on the initiator device.

This step causes the Router to self-identify for 180 seconds. In this duration, the initiator tries to find the identifying devices, queries their capabilities, and creates bindings on the devices with matching operational clusters. As part of this process, the Router can receive an Add Group command and/or a Binding Request command.

LED Indicator table

LED1	LED2	Description
OFF	OFF	The device is not on the network
ON/OFF (Current On/Off cluster status) or Blinking (Identifying)	Blinking every 250ms	Find&Bind active

Available CLI commands

Command	Description
zigbee_factoryreset	Resets the device to its factory state
zigbee_get_network_s	Returns the network status CONNECTED or NOT_CONNECTED
zigbee_get_device_inf	Returns the device info (extended address, installation code, CRC), that would be serialized in the TLV format
zigbee_set_network_i	Set the network information, the device will automatically try to join the network at the end of the download

The following documents are provided in PDF format. Later release may convert the pdf documentation to markdown for better review and aligned format.

- MCXW71/MCXW72 and JN518x Core Utilities User Guide pdf
- Zigbee 3.0 Green Power User Guide pdf

For other NXP platforms that are not part of this NXP SDK delivery vehicle namely K32W061/041M/041AM/JN5189/JN5188, in order to find out more about the Zigbee related documentation, please consult the deliverables and the software offerings available at https://www.nxp.com/products/K32W061_41.

NXP Bluetooth LE Host and Sample Applications

Changelog All notable changes to NXP Bluetooth LE Host will be documented in this file.

NXP Bluetooth LE Host is certified **Bluetooth 6.0**

[1.10.10] - mcux v2025-09-00-pvw2

Improved

- **CS Event Handling**: CS (Channel Sounding) events are now sent to the application task for processing, rather than being handled directly in the Host task
- Various sample applications have been updated

Fixed

- Bluetooth Advertising Sets: Now supports **4 advertising** sets in the Bluetooth host libraries
- Various sample applications bug fixes applied

Changed

- Bluetooth Address Type: The default address type has been changed from **Public to Random Static**

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23

[1.10.9] - mcux v2025-09-00-pvw1

Added

- **IDS event** trigger when incoming ATT packets exceed agreed MTU
- **IDS event** trigger when Unexpected SMP Messages received in idle states (before pairing starts)
- Average RSSI reporting in Anchor Monitor event
- Support for gAppDeferAlgoRun_d in btcs_client.c
- **Multi-connection monitoring** in Handover/Monitor Mode

Improved

- Updated **NBU channel sounding** applications to support **64MHz** clock speed
- Cleanup of commComplete structures that only contain status from hci_interface.h

Fixed

- CCC Application handover monitoring RSSI issue
- Intrusion Detection System not reporting event type
- Extended **NBU armgcc projects** stability
- Advertising Extended Applications when Gap_PeriodicAdvCreateSync fails

Changed

- Updated digital_key_car_anchor applications to configure coding scheme via Host API
- Enhanced RAS handling of ACK Ranging Data in invalid conditions

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23

[1.10.8] - mcux v2025-06-00

Added

- **Gap_SetBondedDeviceName()** to set device name using NVM index
- **RAS** queue for GATT indications sent
- **gHciStatusBase_c** to **csError** status
- Option to use statically allocated **memory** for dynamic **GATT database** (prevents heap fragmentation)
- Checks for **controller** supported features and setting **PAST bits** accordingly
- **Anchor** support to **export** device data via RAS using gAppHciDataLogExport_d = 2
- **Anchor** support to **export** device local HCI data using gAppHciDataLogExport_d = 1
- **Shell commands** to list peer devices and trigger connection handover
- Define for **enabling** optional **CCC** LE Coded **PHY** advertising
- **cs_sync_phy** parameter to mDefaultRangeSettings (**renamed** from outdated RTTPhy)

Improved

- **Stack Host** now saves the most recently set **random address** after successful controller response
- Miscellaneous **minor** application **updates**

Fixed

- Compilation issue in **loc_reader app** with real-time RAS transfer
- **CCC** application **handover state machine** race condition
- **CCC** resets **gCurrentAdvHandle** upon connection
- **RAS** uses correct bit for data overwrite preference

Changed

- Updated **Bluetooth LE Host Documentation**.
- **BLE_Shell** Tx timer interval adjusted for **max throughput** on 1M PHY
- **CS_ConfigVendorCommand** updated with **Inline Phase Return** field
- Renamed **tx_pwr_phy** to **phy** and removed obsolete rtt_phy field
- Updated **documentation** to clarify **Controller Privacy** restrictions

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23

[1.10.7] - mcux v2025-06-00-pvw2

Added

- Support for **Bluetooth LE Debug Keys**
- Support for **pairing failure** reason 0x10 (Busy)
- Extended NBU **Wireless_uart_host battery service**
- **Channel Sounding RSSI Information** at application level
- Application support for **4-antenna configuration**

Improved

- **Clean** include directives
- Allow central-only devices to use **Gap_EncryptAdvertisingData**
- **CSTACK** size optimization for **RADE** using baremetal apps

Fixed

- Extended NBU **memory leak** issues
- Issues when **gAppOtaASyncFlashTransactions_c** is set to 0
- Issue with **CS procedure** affected by the CS data export
- Extended NBU **Wireless_uart_host privacy**

Changed

- Updated **Bluetooth LE Host Documentation**.

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, K32W1

[1.10.6] - mcux v2025-06-00-pvw1

Added

- **Encypted Advertising Data** support in Extendded Advertising Applications.
- Support for **disable UART** for **CS applications** for **low power measurements**.
- Support for **LCE (DSPV) non-blocking API** integration to **RADE**.
- **Intrusion Detection System** as **Experimental**.

Improved

- **L2CAP command length validation** to cover all signaling commands.
- **Extended NBU Wireless_uart_host multiple connections** support.

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, K32W1

[1.10.5] - mcux v2025-03-00

Added

- MCXW72 **Extended NBU** support and **w_uart_host**, **fsci_bridge** and **ncp_fscibb** sample applications.
- **L2CAP support** for Channel Sounding **IQ Sample Transfer** in CCC CS sample applications.
- Bluetooth LE Sample applications for **MCX-W71-EVK** board.

Changed

- Updated **FSCI XML file**.
- Updated **Bluetooth LE Host Documentation**.

Fixed

- Cleared the **mpRemoteCachedCaps** entry when the peer disconnects (CS sample applications).
- Transfer **RAS subscription** data during connection handover (CCC CS sample applications).
- **EAD** - Updated advertising data length check to ensure encrypted data fits inside one AD.
- Updated **digital_key_car_anchor** and **digital_key_car_anchor_cs** applications to manage **Random Static address** from the application layer.

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, K32W1

[1.10.4] - mcux v2025-03-00-pvw2

Added

- PAWR support in **BLE Shell** sample application.
- PAWR support in **adv_ext_peripheral** and **adv_ext_central** sample applications.
- New sample applications for **FRDM-MCXW72**.
- **Gap_SetScanningCallback** API.
- Support for handover connection interval update command.

Changed

- Updated HID Device for **Windows 11** compatibility.
- Updated CCC demos to **Digital Key R4 spec version 1.0.0**.
- Improved RPA resolution at the **Host level**, now performed synchronously.
- Enhanced parsing of the **CS procedure** in Ranging Service.

Fixed

- Corrected parsing of the **PAST command** in FSCI GAP.
- Fixed **scan event reporting** in PAST scenario.
- Added an error case for Gap_SetChannelMap in the generic event handler.

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, K32W1

Bluetooth Low Energy Application Developer's Guide

Introduction This document explains how to integrate the NXP Bluetooth Low Energy Host Stack in an application and provides detailed explanation of the most commonly used APIs and code examples.

- *Introduction*: This section outlines the document structure.
- *Prerequisites*: The document sets out the prerequisites.
- *Bluetooth LE Host Stack Initialization and APIs*: This section describes the Bluetooth Low Energy Host Stack initialization. It also presents the APIs categorized according to the layer and by application role.
- *Generic Access Profile (GAP) Layer*: The Generic Access Profile (GAP) layer is divided into two sections according to the GAP role of the device: Central and Peripheral. The basic setup of two such devices is explained with code examples, such as how to prepare the devices for connections, how to connect them together, and pairing and bonding processes.
- *Generic Attribute Profile (GATT) Layer*: This section describes the Generic Attribute Profile (GATT) layer and introduces the APIs required for data transfer between the two connected devices. This section is divided into two subsections according to the GATT role of the device: Client and Server.
- *GATT database application interface*: The document further describes the usage of the GATT database APIs that allow the application to manipulate data stored in the GATT Server database.
- *Creating GATT database*: This section describes a user-friendly method to build a GATT database statically. The method involves the use of a predefined set of macros that the application can include to build the database at application compile time.
- *Creating a Custom Profile*: This section contains instructions on how to build a custom profile.
- *Application Structure*: The section describes the structure of the typical application.
- *Low-Power Management*: This section describes low-power management and how an application can use the low-power modes of the hardware and software.
- *Over the Air Programming (OTAP)*: This section describes the Over The Air Programming (OTAP) capabilities that the Host Stack offers via a dedicated Service/Profile. The section also describes how to use the OTAP capabilities in an application and also contains a detailed description of the SDK components involved in the OTAP process.
- *Creating a Bluetooth LE application when the Host Stack runs on another processor*: This section describes how to build a Bluetooth Low Energy application when the Host Stack is running on a separate processor.
- *References*: This section lists the documents that can be referred to for more information.
- *Acronyms and abbreviations*: This section lists the acronyms used in this document.

Prerequisites The Bluetooth Low Energy Host Stack library contains several external references that the application must define to enable full functionality.

Attention: Application developers must ensure to define these references to prevent linkage errors when trying to build the application binary.

Task and event queues The task queues are declared in the *ble_host_tasks.h* as follows:

```
/*! App to Host message queue for the Host Task */
    extern messaging_t   gApp2Host_TaskQueue;
/*! HCI to Host message queue for the Host Task */
    extern messaging_t   gHci2Host_TaskQueue;
/*! Event for the Host Task Queue */
    extern OSA_EVENT_HANDLE_DEFINE(gHost_TaskEvent);
```

See Initialization for more details about the RTOS tasks required by the Bluetooth LE Host Stack.

Parent topic:*Prerequisites*

GATT database The application must define and populate the database according to its requirements and constraints either statically, at application compile time, or dynamically.

Regardless of how the application creates the GATT database, the following two external references from *gatt_database.h* must be defined:

```
/*! The number of attributes in the GATT Database. */
extern uint16_t gGattDbAttributeCount_c;
/*! Reference to the GATT database */
extern gattDbAttribute_t* gattDatabase;
```

The attribute template is defined as shown here:

```
typedef struct{
    uint16_t handle ;
/*!< Attribute handle - cannot be 0x0000; attribute handles need not be consecutive, but must be strictly␣
↪increasing. */
    uint16_t permissions ;
/*!< Attribute permissions as defined by ATT. */
    uint32_t uuid ;
/*!< The UUID should be read according to the gattDbAttribute_t.uuidType member: for 2-byte and 4-byte␣
↪UUIDs, this contains the value of the UUID; for 16-byte UUIDs, this is a pointer to the allocated 16-byte␣
↪array containing the UUID. */
    uint8_t * pValue ;
/*!< Pointer to allocated value array. */
    uint16_t valueLength ;
/*!< Size of the value array. */
    uint16_t uuidType : 2;
/*!< Identifies the length of the UUID; the 2-bit values are interpreted according to the bleUuidType_t␣
↪enumeration. */
    uint16_t maxVariableValueLength : 10;
/*!< Maximum length of the attribute value array; if this is set to 0, then the attribute's length␣
↪(valueLength) is fixed and cannot be changed. */
} gattDbAttribute_t ;
```

Parent topic:*Prerequisites*

Non-Volatile Memory (NVM) access The Bluetooth LE Host Stack implements an internal module responsible for managing device information. This module relies on accessing a Non-Volatile Memory module for storing and loading bonded devices data.

The application developers determine the NVM access mechanism through the definition of three functions and one variable. The functions must first pre-process the information and then perform standard NVM operations (erase, write, read). The declarations are as follows:

```
bleResult_t App_NvmErase
(
    uint8_t mEntryIdx
);
bleResult_t App_NvmRead
(
    uint8_t  mEntryIdx,
    void*    pBondHeader,
    void*    pBondDataDynamic,
    void*    pBondDataStatic,
    void*    pBondDataLegacy,
    void*    pBondDataDeviceInfo,
    void*    pBondDataDescriptor,
    uint8_t  mDescriptorIndex
);
bleResult_t App_NvmWrite
(
    uint8_t  mEntryIdx,
    void*    pBondHeader,
    void*    pBondDataDynamic,
    void*    pBondDataStatic,
    void*    pBondDataLegacy,
    void*    pBondDataDeviceInfo,
    void*    pBondDataDescriptor,
    uint8_t  mDescriptorIndex
);
```

The device information is divided into several components to ensure that even software wear leveling mechanisms can be used optimally. The components sizes are fixed (defined in *ble_constants.h*) and have the following meaning:

API pointer to bond component	Component size (*ble_constants.h*)	Description
pBondHeader: points to a bleBondIdentityHeaderBlob_t element	gBleBondIdentityHeaderSize_c	Bonding information which is sufficient to identify a bonded device.
pBondDataDynamic: points to a bleBondDataDynamicBlob_t element	gBleBondDataDynamicSize_c	Bonding information that might change frequently.
pBondDataStatic: points to a bleBondDataStaticBlob_t element	gBleBondDataStaticSize_c	Bonding information that is unlikely to change frequently.
pBondDataLegacy: points to a bleBondDataLegacyBlob_t element	gBleBondDataLegacySize_c	Stores legacy pairing and Connection Signature Resolving Key (CSRK) bond information.
pBondDataDeviceInfo: points to a bleBondDataDeviceInfoBlob_t element	gBleBondDataDeviceInfoSize_c	Additional bonding information that can be accessed using the host stack API.
pBondDataDescriptor: points to a bleBondDataDescriptorBlob_t element	gBleBondDataDescriptorSize_c	Bonding information used to store one Client Characteristic Configuration Descriptor (CCCD).

The Bluetooth LE Host Stack handles the format of the bonding information. Therefore, application developers need not to take care of this aspect.

Each bonding data slot must contain one bonding header blob, one dynamic data blob, one static data blob, one data legacy blob, one device information blob, and an array of descriptor blobs equal to *gcGapMaximumSavedCccds_c.*

Note: *The application must define the* gcGapMaximumSavedCccds_c. *macro according to its requirement. The default value can be found in the* ble_constants.h *file.*)

A slot is uniquely identified by the *mEntryIdx* parameter.

A descriptor is uniquely identified by the pair *mEntryIdx - mDescriptorIndex*.

If one or more pointers passed as parameters are NULL, the read from or write to the corresponding blob of the bonding slot must be ignored. The erase function must clear the entire bonding data slot specified by the entry index.

Note: When Advanced Secure Mode is chosen (gAppSecureMode_d is defined as 1 in app_preinclude.h), two additional application NVM functions are defined to handle local keys encrypted blob storage. Their declaration is:

```
bleResult_t App_NvmWriteLocalKeys
(
    uint8_t mEntryIdx,
    void* pLocalKey
)
bleResult_t App_NvmReadLocalKeys
(
    uint8_t mEntryIdx,
    void* pLocalKey
)
```

The functions write/read a structure of type bleLocalKeysBlob_t into/from NVM using a dedicated data set. The parameter mEntryIdx can be 0 (local IRK is handled) or 1 (local CSRK is handled).

The format of the local keys blob nor about the generation and storage of the local keys is automatically handled in **BLE Connection Manager** (*BleConnManager_GenericEvent*). Therefore the application developer need not manage this aspect.

The current implementation of the aforementioned functions uses either the framework NVM module or a RAM buffer. Additional details about the NVM configuration and functionality can be found in the *Connectivity Framework Reference Manual.* See *References*.

To enable the NVM mechanism, ensure the following points:

- gAppUseNvm_d (in *app_preinclude.h*) is set to 1 and
- gUseNVMLink_d is set to 1 in the linker options of the toolchain.

Note:

- If gAppUseNvm_d is set to 0, then all bonding data is stored in the RAM and is accessible until reset or power cycle.
- If gAppUseNvm_d is set to 1, the default NVM module configurations are applied in the *app_preinclude.h* file.

Parent topic:*Prerequisites*

Bluetooth LE Host Stack Initialization and APIs

Initialization The application developer is required to configure the Host Task as part of the Host Stack requirement. The task is the context for running all the Host layers (GAP, GATT, ATT, L2CAP, SM, GATTDB)

The prototype of the task function is located in the *ble_host_tasks.h* file:

```
void Host_TaskHandler(void * args);
```

It should be called with *NULL* as an argument in the task code from the application.

Application developers are required to define task events and queues as explained in RTOS Task Queues and Events.

If the Controller software runs on the same chip as the Host, the Controller task always has a higher priority than the Host task. The priority value of the Host Task can be configured through the *gHost_TaskPriority_c define* (by default set in *ble_host_task_config.h*). Note that changing this value can have a significant impact on the Bluetooth Low Energy stack.

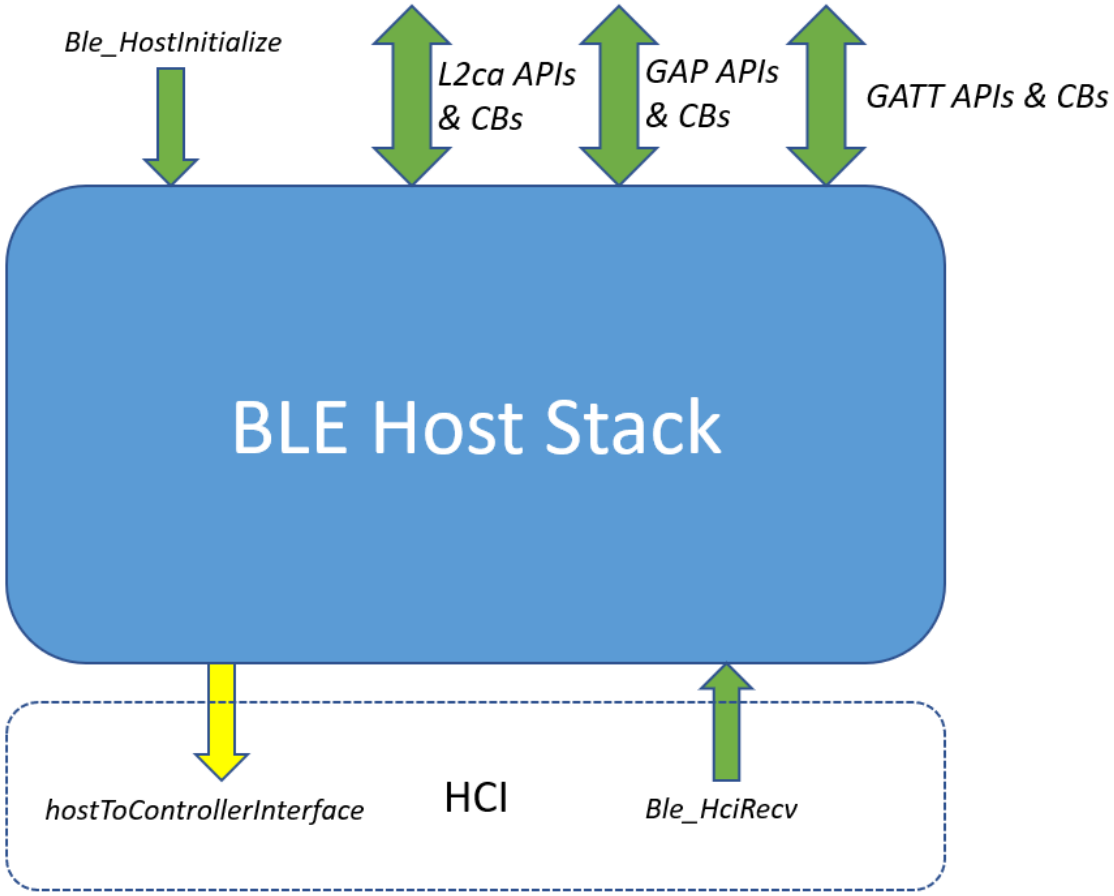
Parent topic:*Bluetooth LE Host Stack Initialization and APIs*

Main function to initialize the Bluetooth LE Host Stack This Figure provides an overview of Bluetooth Low Energy Host Stack. When using the existing application common files, the startup task uses *BluetoothLEHost_AppInit()*, which is defined in *app_conn.h*. The function initializes all components related to the Bluetooth Low Energy application. It has the following prototype:

```
void BluetoothLEHost_AppInit(void);
```

The *BluetoothLEHost_AppInit()* function must be implemented by each application. It should register its generic event callback using *BluetoothLEHost_SetGenericCallback()* and initialize the Bluetooth LE Host Stack layer by calling *BluetoothLEHost_Init()*. The prototype for the *BluetoothLEHost_Init()* function is found in *app_conn.h* and is implemented in *app_conn.c*.

```
void BluetoothLEHost_Init
(
    appBluetoothLEInitCompleteCallback_t pCallback
);
```



BluetoothLEHost_Init takes as parameter a function to be called at the end of Bluetooth LE Host Stack initialization. In this callback, the application can register its callbacks with the Host layer, allocate timers, start services, and perform similar tasks. The callback should have a prototype as follows:

```
static void BluetoothLEHost_Initialized(void);
```

BluetoothLEHost_Init() is responsible for initializing the Host.

Initialize the Bluetooth LE Host Stack after platform setup is complete and all RTOS tasks have been started. The function that should be called for this purpose is located in the *ble_general.h* file and has the following prototype:

```
bleResult_t Ble_HostInitialize
(
    gapGenericCallback_t            genericCallback,
    hciHostToControllerInterface_t  hostToControllerInterface
);
```

Parent topic:*Bluetooth LE Host Stack Initialization and APIs*

HCI entry and exit points The HCI entry point of the Host Stack is the second function located in the *ble_general.h* file:

```
void Ble_HciRecv
(
    hciPacketType_t packetType,
    void* pHciPacket,
    uint16_t packetSize
);
```

This is the function that the application must call to insert an HCI message into the Host.

An equivalent exists, to be used in ISR context:

```
bleResult_t Ble_HciRecvFromIsr
(
    hciPacketType_t     packetType,
    void*               pHciPacket,
    uint16_t            packetSize
);
```

Therefore, the *Ble_HciRecv* function and the *hostToControllerInterface* parameter of the *Ble_HostInitialize* function represent the two points that need to be connected to the LE Controller (see Bluetooth Low Energy Host Stack overview), either directly (if the Controller software runs on the same chip as the Host) or through a physical interface (for example, UART).

Parent topic:*Bluetooth LE Host Stack Initialization and APIs*

Bluetooth LE Host Stack libraries and API availability All the APIs referenced in this document are available in the Central and Peripheral libraries. The support for Bluetooth 5.3 optional features such as Advertising, Advertising Extensions, GATT Caching, and EATT are provided in separate host libraries. They are distributed in a similar process as the legacy ones using GAP/GATT role support, which is described as follows.

For example, below are listed the full-featured libraries with complete support for both Central and Peripheral APIs, at GAP level.

- *lib_ble_OPT_host_cm33_iar.a* (for IAR projects)
- *lib_ble_OPT_host_cm33_gcc.a* (for MCUX projects)

These libraries include optional features implemented by the Bluetooth LE Host. For applications that need to use only the mandatory 5.3 Bluetooth LE and below features, the *lib_ble_host_cm33_iar.a* or *lib_ble_host_cm33_gcc.a* libraries can be used instead.

However, some applications may be targeted to memory-constrained devices and do not need the full support. In the interest of reducing code size and RAM utilization, optimized libraries are provided:

- *lib_ble_host_peripheral_cm33_iar.a/ lib_ble_host_peripheral_cm33_gcc.a* and
- *lib_ble_OPT_host_peripheral_cm33_iar.a / lib_ble_OPT_host_peripheral_cm33_gcc.a.*
  - Support only APIs for the GAP Peripheral and GAP Broadcaster roles
  - Support only APIs for the GATT Server role
- *lib_ble_host_central_cm33_iar.a* and *lib_ble_OPT_host_central_cm33_iar.a*
- *lib_ble_host_central_cm33_gcc.a* and *lib_ble_OPT_host_central_cm33_gcc.a*
  - Support only APIs for the GAP Central and GAP Observer roles
  - Support only APIs for the GATT Client role

If one attempts to use an API that is not supported (for instance, calling *Gap_Connect* with the *lib_ble_host_peripheral_cm33_iar.a* and *lib_ble_host_peripheral_cm33_gcc.a*), then the API returns the *gBleFeatureNotSupported_c* error code.

Similarly, if the API for OPT is used with a host library that does not have support for optional features, then *gBleFeatureNotSupported_c* is returned. For instance, calling *Gap_SetExtAdvertising* parameters with the *lib_ble_host_peripheral_cm33_iar.a* and *lib_ble_host_peripheral_cm33_gcc.a*) returns the exit code *gBleFeatureNotSupported_c*.

Note: See the *Bluetooth Low Energy Host Stack API Reference Manual* for explicit information regarding API support. Each function documentation contains this information in the Remarks section.

Parent topic:*Bluetooth LE Host Stack Initialization and APIs*

Synchronous and asynchronous functions The vast majority of the GAP and GATT APIs are executed **asynchronously**. Calling these functions generates a message and places it in the Host Task message queue.

Therefore, the actual result of these APIs is signaled in **events** triggered by specific callbacks installed by the application. See the *Bluetooth Low Energy Host Stack API Reference Manual* for specific information about the events that are triggered by each API.

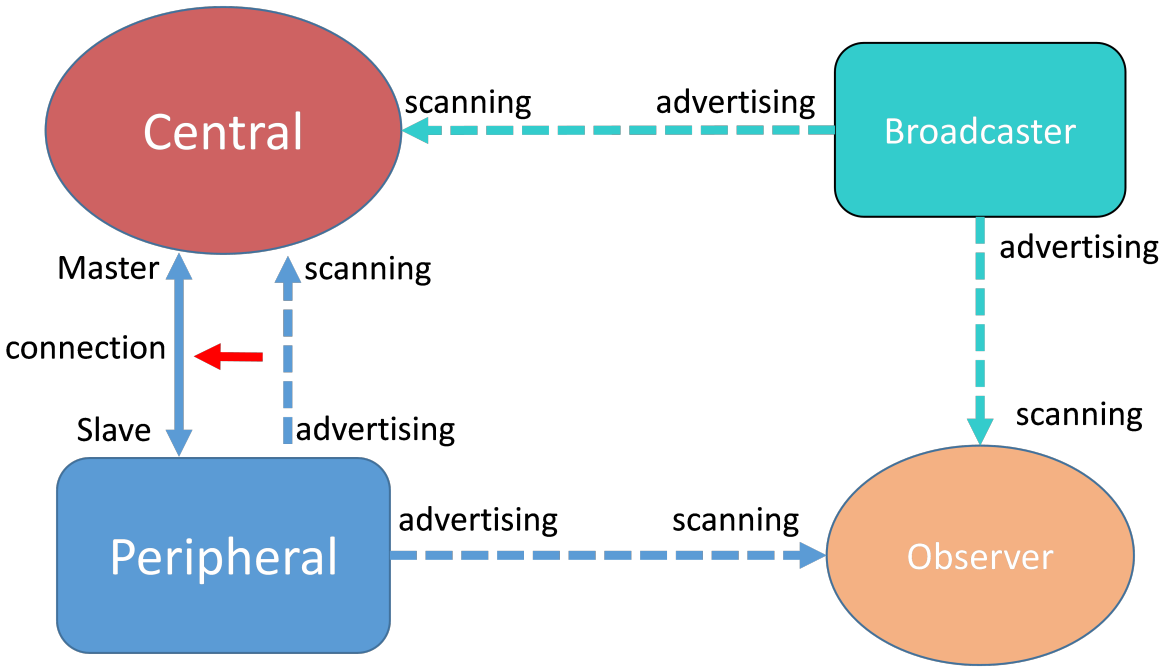
However, there are a few APIs which are executed immediately (**synchronously**). This is explicitly mentioned in the *Bluetooth Low Energy Host Stack API Reference Manual* in the *Remarks* section of each function documentation.

If nothing is mentioned, then the API is asynchronous.

Parent topic:*Bluetooth LE Host Stack Initialization and APIs*

Radio TX Power level The controller interface includes APIs that can be used to set the Radio TX Power to a different level than the default one.

The power level can be set differently for advertising and connection channels by calling the function *Controller_SetTxPowerLevelDbm()* with the channel parameter set to *gAdvTxChannel_c* or *gConnTxChannel_c*.



Parent topic:*Bluetooth LE Host Stack Initialization and APIs*

Generic Access Profile (GAP) Layer The GAP layer manages connections, security, and bonded devices.

The GAP layer APIs are built on top of the Host-Controller Interface (HCI), the Security Manager Protocol (SMP), and the Device database.

GAP defines four possible roles that a Bluetooth Low Energy device may have in a Bluetooth Low Energy system:

- **Central**
  - Scans for advertisers (Peripherals and Broadcasters)
  - Initiates connection to Peripherals; Central at Link Layer (LL) level
  - Usually acts as a GATT Client, but can also contain a GATT Database itself
- **Peripheral**
  - Advertises and accepts connection requests from Central devices; LL Peripheral
  - Usually contains a GATT Database and acts as a GATT Server, but may also be a Client
- **Observer**
  - Scans for advertisers, but does not initiate connections; Transmit is optional
- **Broadcaster**
  - Advertises, but does not accept connection requests from Central devices; Receive is optional

The Figure illustrates the generic GAP topology.

Peripheral setup The Peripheral starts advertising and waits for scan and connection requests from other Central devices.

Advertising Before starting advertising, the advertising parameters should be configured. Otherwise, the following defaults are used.

```
#define gGapDefaultAdvertisingParameters_d \
{
   /* minInterval */      gGapAdvertisingIntervalDefault_c, \
   /* maxInterval */      gGapAdvertisingIntervalDefault_c, \
   /* advertisingType */ gConnectableUndirectedAdv_c, \
   /* addressType */      gBleAddrTypePublic_c, \
   /* peerAddressType */  gBleAddrTypePublic_c, \
   /* peerAddress */      {0U, 0U, 0U, 0U, 0U, 0U}, \
   /* channelMap */       (gapAdvertisingChannelMapFlags_t)gGapAdvertisingChannelMapDefault_c,  \
   /* filterPolicy */     gProcessAll_c \
}
```

To set different advertising parameters, a *gapAdvertisingParameters_t* structure should be allocated and initialized with defaults. Then, the necessary fields may be modified.

After that, the following function should be called:

```
bleResult_t Gap_SetAdvertisingParameters
(
    const gapAdvertisingParameters_t *      pAdvertisingParameters
);
```

The application should listen to the *gAdvertisingParametersSetupComplete_c* generic event.

Next, the advertising data should be configured and, if the advertising type supports active scanning, the scan response data should also be configured. If either of these is not configured, they are defaulted to empty data.

The function used to configure the advertising and/or scan response data is shown here:

```
bleResult_t Gap_SetAdvertisingData
(
  const gapAdvertisingData_t *      pAdvertisingData,
  const gapScanResponseData_t *     pScanResponseData
);
```

Either of the two pointers may be *NULL*, in which case they are ignored (the corresponding data is left as it was previously configured, or empty if it has never been set), but not both at the same time.

The application should listen to the *gAdvertisingDataSetupComplete_c* generic event.

After all the necessary setup is done, advertising may be started with this function:

```
bleResult_t Gap_StartAdvertising
(
    gapAdvertisingCallback_t advertisingCallback,
    gapConnectionCallback_t connectionCallback
);
```

The advertising callback is used to receive advertising events (advertising state changed or advertising command failed), while the connection callback is only used if a connection is established during advertising.

The connection callback is the same as the callback used by the Central when calling the *Gap_Connect* function.

When using the common application structure, the application can use the following API defined in *app_conn.h*:

```
bleResult_t BluetoothLEHost_StartAdvertising
(
    appAdvertisingParams_t    *pAdvParams,
    gapAdvertisingCallback_t pfAdvertisingCallback,
    gapConnectionCallback_t   pfConnectionCallback
);
```

The API goes through the steps of setting the advertising data and parameters. Events from the Host task are treated in the *App_AdvertiserHandler()* function, implemented in *app_advertiser.c*. To set the advertising parameters and data *BluetoothLEHost_StartAdvertising* requires a parameter of the following type:

```
typedef struct
appAdvertisingParams_tag
{
 gapAdvertisingParameters_t *pGapAdvParams; /*!< Pointer to the GAP advertising parameters */
 const gapAdvertisingData_t *pGapAdvData; /*!< Pointer to the GAP advertising data */
 const gapScanResponseData_t *pScanResponseData;
 /*!< Pointer to the scan response data */ } appAdvertisingParams_t;
```

If a Central initiates a connection to this Peripheral, the *gConnEvtConnected_c* connection event is triggered.

To stop advertising while the Peripheral has not yet received any connection requests, use this function:

```
bleResult_t Gap_StopAdvertising (void);
```

This function should not be called after the Peripheral enters a connection, as the advertising automatically stops in this case.

Parent topic: Peripheral setup

Pairing and bonding (peripheral) After a connection has been established to a Central, the Peripheral's role regarding security is a passive one. It is the responsibility of the Central device to start the pairing process. In case, the devices have already bonded in the past, the Central encrypts the link using the shared LTK.

The Peripheral sends error responses (at ATT level) with proper error code if the Central attempts to access sensitive data without authenticating. Examples of such error responses are: Insufficient Authentication, Insufficient Encryption, Insufficient Authorization, and so on. Therefore, it indicates to the Central that it needs to perform security procedures.

All security checks are performed internally by the GAP module and the security error responses are sent automatically. All the application developer needs to do is register the security requirements.

First, when building the GATT Database (see *Creating GATT database*), the sensitive attributes should have the security built into their access permissions (for example, read-only / read with authentication / write with authentication / write with authorization, and so on.).

Second, if the GATT Database requires additional security besides that already specified in attribute permissions (for example, certain services require higher security in certain situations), the following function must be called:

```
bleResult_t Gap_RegisterDeviceSecurityRequirements
(
    const gapDeviceSecurityRequirements_t * pSecurity
);
```

The parameter is a pointer to a structure which contains a "device security setting" and service-specific security settings. All these security requirements are pointers to gapSecurityRequirements_t structures. The pointers that are to be ignored should be set to NULL.

Although the Peripheral does not initiate any kind of security procedure, it can inform the Central about its security requirements. This is usually done immediately after the connection to avoid exchanging useless packets for requests that might be denied because of insufficient security.

The informing is performed through the Peripheral Security Request packet at SMP level. To use it, the following GAP API is provided:

```
bleResult_t Gap_SendPeripheralSecurityRequest
(
    deviceId_t                      deviceId,
    const gapPairingParameters_t* pPairingParameters
);
```

The gapPairingParameters_t structure includes two important fields. The withBonding field indicates to the Central whether this Peripheral can bond and the securityModeAndLevel field informs about the required security mode and level that the Central should pair for. See Pairing and bonding (Central) for an explanation about security modes and levels, as defined by the GAP module.

This request expects no reply, nor any immediate action from the Central. The Central may easily choose to ignore the Peripheral Security Request.

If the two devices have bonded in the past, the Central proceeds directly to encrypting the link. If the bond was not made using LE Secure Connections, the Peripheral expects to receive a gConnEvtLongTermKeyRequest_c connection event. If the bond was made using LE Secure Connections, the Host provides the LTK automatically to the LE Controller.

When the devices have been previously pairing without using LE Secure Connections, along with the Peripheral's LTK, the EDIV (2 bytes) and RAND (8 bytes) values were also sent (their meaning is defined by the SMP). Therefore, before providing the key to the Controller, the application should check that the two values match with those received in the gConnEvtLongTermKeyRequest_c event. If they do, the application should reply with:

```
bleResult_t Gap_ProvideLongTermKey
(
    deviceId_t          deviceId,
    const uint8_t       aLtk,
    uint8_t             ltkSize
);
```

The LTK size cannot exceed the maximum value of 16.

If the EDIV and RAND values do not match, or if the Peripheral does not recognize the bond, it can reject the encryption request with:

```
bleResult_t Gap_DenyLongTermKey
(
    deviceId_t deviceId
);
```

If LE SC Pairing was used then the LTK is generated internally by the Bluetooth LE Host Stack and it is not requested from the application during post-bonding link encryption. In this scenario, the application is only notified of the link encryption through the gConnEvtEncryptionChanged_c connection event.

If the devices are not bonded, the Peripheral should expect to receive the gConnEvtPairingRequest_c, indicating that the Central has initiated pairing.

If the application agrees with the pairing parameters (see Pairing and bonding (Central) for detailed explanations), it can reply with:

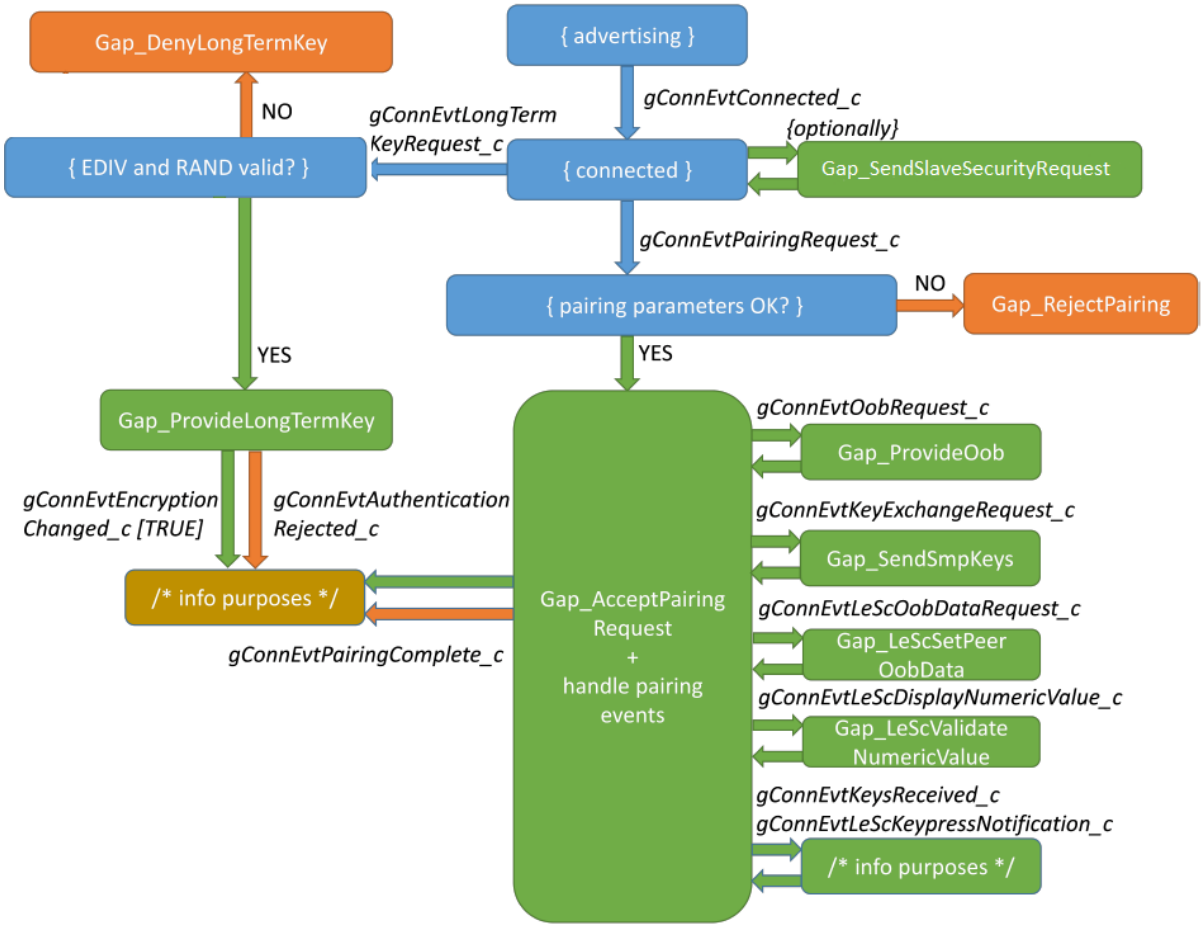
```
bleResult_t Gap_AcceptPairingRequest
(
    deviceId_t                      deviceId,
    const gapPairingParameters_t *    pPairingParameters
);
```

This time, the Peripheral sends its own pairing parameters, as defined by the SMP.

After sending this response, the application should expect to receive the same pairing events as the Central (see Pairing and bonding (Central)), with one exception: the gConnEvtPasskeyRequest_c event is not called if the application sets the Passkey (PIN) for pairing before the connection by calling the API:

```
bleResult_t Gap_SetLocalPasskey
(
    uint32_t passkey
);
```

This is done because, usually, the Peripheral has a static secret PIN that it distributes only to trusted devices. If, for any reason, the Peripheral must dynamically change the PIN, it can call the aforementioned function every time it wants to, before the pairing starts (for example, right before sending the pairing response with Gap_AcceptPairingRequest).



If the Peripheral application never calls Gap_SetLocalPasskey, then the gConnEvtPasskeyRequest_c event is sent to the application as usual.

The Peripheral can use the following API to reject the pairing process:

```
bleResult_t Gap_RejectPairing
(
deviceId_t                      deviceId,
gapAuthenticationRejectReason_t    reason
);
```

The reason should indicate why the application rejects the pairing. The value gLinkEncryptionFailed_c is reserved for the gConnEvtAuthenticationRejected_c connection event to indicate the link encryption failure rather than pairing failures. Therefore, it is not meant as a pairing reject reason.

The Gap_RejectPairing function may be called not only after the Pairing Request was received, but also during the pairing process. For example, when handling pairing events or asynchronously, if for any reason the Peripheral decides to abort the pairing, this function can be called. This also holds true for the Central. Figure illustrates the Peripheral pairing flow and lists the main APIs and events. Gap_RejectPairing can be called on any pairing event.

For both the Central and the Peripheral, bonding is performed internally and is not the application's concern. The gConnEvtPairingComplete_c event parameters inform the application if bonding has occurred.

Parent topic: Peripheral setup

Parent topic:*Generic Access Profile (GAP) Layer*

Central setup Usually, a Central must start scanning to find Peripherals. When the Central has scanned a Peripheral it wants to connect to, it stops scanning and initiates a connection to that Peripheral. After the connection has been established, it may start pairing, if the Peripheral requires it, or directly encrypt the link, if the two devices have already bonded in the past.

Scanning The most basic setup for a Central device begins with scanning, which is performed by the following function from *gap_interface.h*:

```
bleResult_t Gap_StartScanning
(
  const gapScanningParameters_t* pScanningParameters,
  gapScanningCallback_t scanningCallback,
  gapFilterDuplicates_t enableFilterDuplicates,
  uint16_t duration,
  uint16_t period
);
```

If the *pScanningParameters* pointer is NULL, the currently set parameters are used. If no parameters have been set after a device power-up, the standard default values are used:

```
#define gGapDefaultScanningParameters_d \
{ \
    /* type */              gGapScanTypePassive_c, \
    /* interval */          gGapScanIntervalDefault_d, \
    /* window */              gGapScanWindowDefault_d, \
    /* ownAddressType */    gBleAddrTypePublic_c, \
    /* filterPolicy */      gScanAll_c \
    /* scanning PHY */      gLePhylMFlag_c\
}
```

The easiest way to define non-default scanning parameters is to initialize a *gapScanningParameters_t* structure with the above default and change only the required fields.

For example, to perform active scanning and only scan for devices in the Filter Accept List, the following code can be used:

```
gapScanningParameters_t scanningParameters = gGapDefaultScanningParameters_d;
scanningParameters.type = gGapScanTypeActive_c;
scanningParameters.filterPolicy = gScanWithFilterAcceptList_c;
Gap_StartScanning(&scanningParamters, scanningCallback, enableFilterDuplicates, duration, period);
```

When using the common application structure, the application can use the following API defined in *app_conn.h*:

```
bleResult_t BluetoothLEHost_StartScanning
(
    appScanningParams_t    *pAppScanParams,
    gapScanningCallback_t pfCallback
);
```

The API uses the *appScanningParams_t* structure, which is defined as follows:

```
typedef struct appScanningParams_tag
{
    gapScanningParameters_t *pHostScanParams;         /*!< Pointer to host scan structure */
    gapFilterDuplicates_t enableDuplicateFiltering;   /*!< Duplicate filtering mode */
    uint16_t duration;                                /*!< scan duration  */
    uint16_t period;                                  /*!< scan period  */
} appScanningParams_t;
```

The *scanningCallback* is triggered by the GAP layer to signal events related to scanning.

The most important event is the *gDeviceScanned_c* event, which is triggered each time an advertising device is scanned. This event data contains information about the advertiser:

```
typedef struct
{
    bleAddressType_t                addressType ;
    bleDeviceAddress_t              aAddress ;
    int8_t                         rssi ;
    uint8_t                         dataLength ;
    uint8_t*                        data ;
    bleAdvertisingReportEventType_t   advEventType ;
    bool_t                          directRpaUsed;
    bleDeviceAddress_t              directRpa;
    bool_t                          advertisingAddressResolved;
} gapScannedDevice_t;
```

If this information signals a known Peripheral that the Central wants to connect to, the latter must stop scanning and connect to the Peripheral.

To stop scanning, call this function:

```
bleResult_t Gap_StopScanning (void);
```

By default, the GAP layer is configured to report all scanned devices to the application using the *gDeviceScanned_c* event type. However, some use cases might require to perform specific GAP Discovery Procedures. In such use cases the advertising reports might require the filtering of Flags AD value from the advertising data. Other use cases require the Bluetooth LE Host Stack to automatically initiate a connection when a specific device has been scanned.

To enable filtering based on the Flags AD value or to set device addresses for automatic connections, the following function must be called before the scanning is started:

```
bleResult_t Gap_SetScanMode
(
    gapScanMode_t           scanMode,
    gapAutoConnectParams_t* pAutoConnectParams,
    gapConnectionCallback_t connCallback
);
```

The default value for the scan mode is *gDefaultScan_c*, which reports all packets regardless of their content and does not perform any automatic connection.

To enable Limited Discovery, the *gLimitedDiscovery_c* value must be used, while the *gGeneralDiscovery_c* value activates General Discovery.

To enable automatic connection when specific devices are scanned, the *gAutoConnect_c* value must be set, in which case the *pAutoConnectParams* parameter must point to the structure that holds the target device addresses and the connection parameters to be used by the Host for these devices.

If scanMode is set to *gAutoConnect_c*, connCallback must be set and is triggered by GAP to send the events related to the connection.

Parent topic: Central setup

Initiating and closing a connection To connect to a scanned Peripheral, extract its address and address type from the *gDeviceScanned_c* event data, stop scanning, and call the following function:

```
bleResult_t Gap_Connect
(
const gapConnectionRequestParameters_t * pParameters,
gapConnectionCallback_t connCallback
);
```

When using the common application structure, the application can also use the following API defined in *app_conn.h*:

```
bleResult_t BluetoothLEHost_Connect
(
    gapConnectionRequestParameters_t*   pParameters,
    gapConnectionCallback_t             connCallback
);
```

An easy way to create the connection parameter structure is to initialize it with the defaults, then change only the necessary fields. The default structure is defined as shown here:

```
#define gGapDefaultConnectionRequestParameters_d \
{ \
    /* scanInterval */      gGapScanIntervalDefault_d, \
    /* scanWindow */        gGapScanWindowDefault_d, \
    /* filterPolicy */      gUseDeviceAddress_c, \
```

(continues on next page)

(continued from previous page)

```
    /* ownAddressType */      gBleAddrTypePublic_c, \
    /* peerAddressType */     gBleAddrTypePublic_c, \
    /* peerAddress */         { 0, 0, 0, 0, 0, 0 }, \
    /* connIntervalMin */     gGapDefaultMinConnectionInterval_d, \
    /* connIntervalMax */     gGapDefaultMaxConnectionInterval_d, \
    /* connLatency */         gGapDefaultConnectionLatency_d, \
    /* supervisionTimeout */ gGapDefaultSupervisionTimeout_d, \
    /* connEventLengthMin */ gGapConnEventLengthMin_d, \
    /* connEventLengthMax */ gGapConnEventLengthMax_d \
    /* initiatingPHYs      */ gLePhylMFlag_c \
}
```

In the following example, Central scans for a specific Heart Rate Sensor with a known address. When it finds it, it immediately connects to it.

```
static void BleApp_ScanningCallback
(
    gapScanningEvent_t *pScanningEvent
)
{
    switch (pScanningEvent->eventType)
    {
        case gDeviceScanned_c:
        {
            if (BleApp_CheckScanEvent(&pScanningEvent->eventData.scannedDevice))
            {
                gConnReqParams.peerAddressType = pScanningEvent->eventData.scannedDevice.addressType;
                FLib_MemCpy(gConnReqParams.peerAddress,
                        pScanningEvent->eventData.scannedDevice.aAddress,
                        sizeof(bleDeviceAddress_t));
                (void)Gap_StopScanning();
#if gAppUsePrivacy_d
                gConnReqParams.usePeerIdentityAddress =  pScanningEvent->eventData.scannedDevice.
↪advertisingAddressResolved;
#endif
                (void)BluetoothLEHost_Connect(&gConnReqParams, BleApp_ConnectionCallback);
            }
        }
        break;
}
```

The *connCallback* is triggered by GAP to send all events related to the active connection. It has the following prototype:

```
typedef void (* gapConnectionCallback_t )
(
    deviceId_t              deviceId,
    gapConnectionEvent_t * pConnectionEvent
);
```

The very first event that should be listened inside this callback is the *gConnEvtConnected_c* event. If the application decides to drop the connection establishment before this event is generated, it should call the following macro:

```
#define Gap_CancelInitiatingConnection()\
    Gap_Disconnect(gCancelOngoingInitiatingConnection_d)
```

This is useful, for instance, when the application chooses to use an expiration timer for the connection request.

Upon receiving the *gConnEvtConnected_c* event, the application may proceed to extract the necessary parameters from the event data (*pConnectionEvent->event.connectedEvent*). The most im-

portant parameter to be saved is the *deviceId*.

The *deviceId* is a unique 8-bit, unsigned integer, used to identify an active connection for subsequent GAP and GATT API calls. All functions related to a certain connection require a *deviceId* parameter. For example, to disconnect, call this function:

```
bleResult_t Gap_Disconnect
(
    deviceId_t deviceId
);
```

Parent topic: Central setup

Pairing and bonding (Central) After the user has connected to a Peripheral, use the following function to check whether this device has bonded in the past:

```
bleResult_t Gap_CheckIfBonded
(
    deviceId_t    deviceId,
    bool_t *      pOutIsBonded
    uint8_t*      pOutNvmIndex
);
```

If it has, link encryption can be requested with:

```
bleResult_t Gap_EncryptLink
(
    deviceId_t      deviceId
);
```

If the link encryption is successful, the *gConnEvtEncryptionChanged_c* connection event is triggered. Otherwise, a *gConnEvtAuthenticationRejected_c*event is received with the *rejectReason* event data parameter set to *gLinkEncryptionFailed_c*.

On the other hand, if this is a new device (not bonded), pairing may be started as shown here:

```
bleResult_t Gap_Pair
(
    deviceId_t                      deviceId,
    const gapPairingParameters_t *    pPairingParameters
);
```

The pairing parameters are shown here:

```
typedef struct gapPairingParameters_tag {
    bool_t                      withBonding ;
    gapSecurityModeAndLevel_t      securityModeAndLevel ;
    uint8_t                     maxEncryptionKeySize ;
    gapIoCapabilities_t            localIoCapabilities ;
    bool_t                      oobAvailable ;
    gapSmpKeyFlags_t               centralKeys ;
    gapSmpKeyFlags_t               peripheralKeys ;
    bool_t                      leSecureConnectionSupported ;
    bool_t                      useKeypressNotifications ;
} gapPairingParameters_t;
```

The names of the parameters are self-explanatory. The *withBonding* flag should be set to *TRUE* if the Central must/wants to bond.

When Advanced Secure Mode is enabled, (*gAppSecureMode_d* id defined as *1* in *app_preinclude.h*), the security mode and level for pairing is automatically enforced as Mode 1 Level 4, and LE Secure Connection Supported is automatically enforced TRUE. Legacy pairing is not supported in this mode.

For the Security Mode and Level, the GAP layer defines them as follows:

- Security Mode 1 Level 1 stands for no security requirements.
- Except for Level 1 (which is only used with Mode 1), Security Mode 1 requires encryption, while Security Mode 2 requires data signing.
- Mode 1 Level 2 and Mode 2 Level 1 do not require authentication (in other words, they allow Just Works pairing, which has no MITM protection). Mode 1 Level 3 and Mode 2 Level 2 require authentication (must pair with PIN or OOB data, which provide MITM protection).
- Starting with Bluetooth specification 4.2, OOB pairing offers MITM protection only in certain conditions. The application must inform the stack if the OOB data exchange capabilities offer MITM protection via a dedicated API.
- Security Mode 1 Level 4 is reserved for authenticated pairing (with MITM protection) using a LE Secure Connections pairing method.
- If a pairing method is used but it does not offer MITM protection, then the pairing parameters must use Security Mode 1 level 2. If the requested pairing parameters are incompatible (for example, Security Mode 1 Level 4 without LE Secure Connections enabled), a gBleInvalidParameter_c status is returned by the security API functions: Gap_SetDefaultPairingParameters, Gap_SendPeripheralSecurityRequest, Gap_Pair and Gap_AcceptPairingRequest.

—	No security	No MITM protection	Legacy MITM protection	LE secure connections with MITM protection
Mode 1 (encryption) distributed LTK (EDIV+RAND) or generated LTK	**Level 1** no security	**Level 2** unauthenticated encryption	**Level 3** authenticated encryption	**Level 4** LE SC authenticated encryption
Mode 2 (data signing) distributed CSRK	—	**Level 1** unauthenticated data signing	**Level 2** authenticated data signing	—

The *centralKeys* should have the flags set for all the keys that are available in the application. The IRK is mandatory if the Central is using a Private Resolvable Address, while the CSRK is necessary if the Central wants to use data signing. The LTK is provided by the Peripheral and should only be included if the Central intends on becoming a Peripheral in future reconnections (GAP role change).

The *peripheralKeys* should follow the same guidelines. The LTK is mandatory if encryption is to be performed, while the peer's IRK should be requested if the Peripheral is using Private Resolvable Addresses.

See table below for detailed guidelines regarding key distribution.

The first three rows are both guidelines for Pairing Parameters (*centralKeys* and *peripheralKeys*) and for distribution of keys with *Gap_SendSmpKeys*.

If LE Secure Connections Pairing is performed (Bluetooth Low Energy 4.2 and above), then the LTK is generated internally, so the corresponding bits in the key distribution fields from the pairing parameters are ignored by the devices.

The Identity Address is distributed if the IRK is also distributed (its flag has been set in the Pairing Parameters). Therefore, it can be "asked" only by asking for IRK (it does not have a separate flag in a *gapSmpKeyFlags_t* structure). Therefore, it is N/A.

The negotiation of the distributed keys is as follows:

- In the SMP Pairing Request (started by *Gap_Pair*), the Central sets the flags for the keys it wants to distribute (*centralKeys*) and receive (*peripheralKeys*).

	Central keys (Central)	Peripheral keys (Central)	Peripheral () keys	Central keys (peripheral)
Long Term Key (LTK)+EDIV +RAND	If it wants to be a peripheral in a future reconnection	If it wants encryption	If it wants encryption	If it wants to become a central in a future reconnection
Identity Resolving Key (IRK)	If it uses or intends to use private resolvable addresses	If a peripheral is using a private resolvable address	If it uses or intends to use private resolvable addresses	If a central is using a private resolvable address
Connection Signature Resolving Key (CSRK)	If it wants to sign data as GATT Client	If it wants the peripheral to sign data as GATT Client	If it wants to sign data as GATT Client	If it wants the Central to sign data as GATT Client
Identity address	If it distributes the IRK	N/A	If it distributes the IRK	N/A

- The Peripheral examines the two distributions and must send an SMP Pairing Response (started by the *Gap_AcceptPairingRequest*) after performing any changes it deems necessary. The Peripheral is only allowed to set to 0 some flags that are set to 1 by the Central, but not the other way around. For example, it cannot request/distribute keys that were not offered/requested by the Central. If the Peripheral is adverse to the Central's distributions, it can reject the pairing by using the *Gap_RejectPairing* function.
- The Central examines the updated distributions from the Pairing Response. If it is adverse to the changes made by the Peripheral, it can reject the pairing (*Gap_RejectPairing*). Otherwise, the pairing continues and, during the key distribution phase (the *gConnEvtKeyExchangeRequest_c* event) only the final negotiated keys are included in the key structure sent with *Gap_SendSmpKeys*.
- For LE Secure Connections (both devices set the SC bit in the AuthReq field of the Pairing Request and Pairing Response packets), the LTK is not distributed. It is generated and the corresponding bit in the Initiator Key Distribution and Responder Key Distribution fields of the Pairing Response packet are set to 0.

If LE Secure Connections Pairing (Bluetooth LE 4.2 and above) is used, and OOB data needs to be exchanged, the application must obtain the local LE SC OOB Data from the Bluetooth LE Host Stack by calling the *Gap_LeScGetLocalOobData* function. The data is contained by the generic *gLeScLocalOobData_c* event.

The local LE SC OOB Data is refreshed in the following situations:

- The *Gap_LeScRegeneratePublicKey* function is called (the *gLeScPublicKeyRegenerated_c* generic event is also generated as a result of this API).
- The device is reset (which also causes the Public Key to be regenerated).

If the pairing continues, the following connection events may occur:

- **Request events**
  - *gConnEvtPasskeyRequest_c*: a PIN is required for pairing; the application must respond with the *Gap_EnterPasskey(deviceId, passkey).*
  - *gConnEvtOobRequest_c*: if the pairing started with the *oobAvailable* set to *TRUE* by both sides; the application must respond with the *Gap_ProvideOob(deviceId, oob).*
  - *gConnEvtKeyExchangeRequest_c*: the pairing has reached the key exchange phase; the application must respond with the *Gap_SendSmpKeys(deviceId, smpKeys).*
  - *gConnEvtLeScOobDataRequest_c*: the stack requests the LE SC OOB Data received from the peer (r, Cr and Addr); the application must respond with *Gap_LeScSetPeerOobData(deviceId, leScOobData).*

  - *gConnEvtLeScDisplayNumericValue_c*: the stack requests the display and confirmation of the LE SC Numeric Comparison Value; the application must respond with *Gap_LeScValidateNumericValue(deviceId, ncvValidated).*

- **Informational events**
  - *gConnEvtKeysReceived_c*: the key exchange phase is complete; keys are automatically saved in the internal device database and are also provided to the application for immediate inspection; application does not have to save the keys in NVM storage because this is done internally if *withBonding*was set to TRUE by both sides.
  - *gConnEvtAuthenticationRejected_c*: the peer device rejected the pairing; the *rejectReason* parameter of the event data indicates the reason that the Peripheral does not agree with the pairing parameters (it cannot be *gLinkEncryptionFailed_c* because that reason is reserved for the link encryption failure).
  - *gConnEvtPairingComplete_c*: the pairing process is complete, either successfully, or an error may have occurred during the SMP packet exchanges; note that this is different from the *gConnEvtKeyExchangeRequest_c* event; the latter signals that the pairing was rejected by the peer, while the former is used for failures due to the SMP packet exchanges.
  - *gConnEvtLeScKeypressNotification_c*: the stack informs the application that a remote SMP Keypress Notification has been received during Passkey Entry Pairing Method.

After the link encryption or pairing is completed successfully, the Central may immediately start exchanging data using the GATT APIs. Gap_RejectPairing may be called on any pairing event.

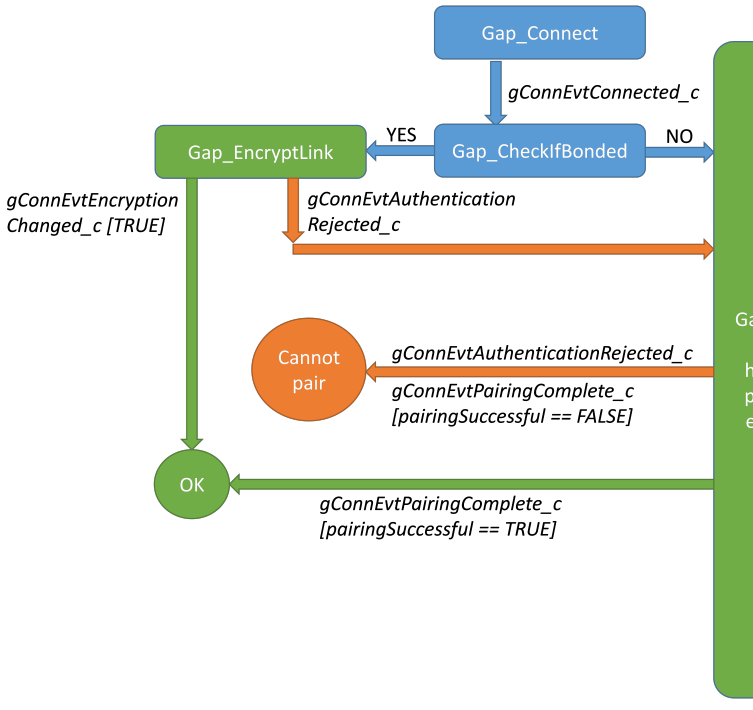


Figure 4. Central pairing flow – APIs and events.

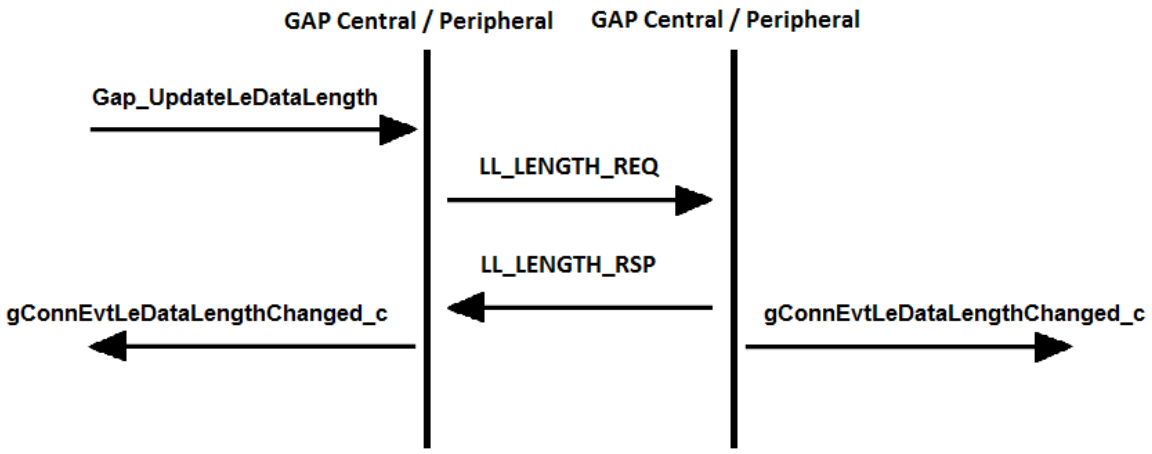
Parent topic: Central setup

Parent topic:*Generic Access Profile (GAP) Layer*

LE data packet length extension This new feature extends the maximum data channel payload length from 27 to 251 octets.

The length management is done automatically by the link layer immediately after the connection is established. The stack passes the default values for maximum transmission number of payload octets and maximum packet transmission time that the application configures at compilation time in *ble_config.h*:



```
#ifndef gBleDefaultTxOctets_c
#define gBleDefaultTxOctets_c         0x00FB
#endif

#ifndef gBleDefaultTxTime_c
#define gBleDefaultTxTime_c           0x0848
#endif
```

The device can update the data length anytime, while in connection. The function that triggers this mechanism is the following:

```
bleResult_t Gap_UpdateLeDataLength
(
    deviceId_t          deviceId,
    uint16_t    txOctets,
    uint16_t    txTime
);
```

After the procedure executes, a *gConnEvtLeDataLengthChanged_c* connection event is triggered with the maximum values for number of payload octets and time to transmit and receive a link layer data channel PDU. The event is send event if the remote device initiates the procedure. This procedure is shown in Figure. **Figure 5. Data Length Update Procedure**

Parent topic:*Generic Access Profile (GAP) Layer*

Privacy feature

Introduction Starting with Bluetooth 4.2, Privacy can be enabled either in the Host or in the Controller:

- **Host Privacy** consists of two use cases that are described in detail in the following sections. These are:
  - Random address generation - Periodically regenerating a random address (Resolvable or Non-Resolvable Private Address) inside the Host and then applying it into the Controller.
  - Random address resolution - Trying to resolve incoming RPAs using the IRKs stored in the bonded devices list. The address resolution is performed when a connection is established with a device or for the autoconnect scan. The advertising packets that have an RPA are not resolved automatically due to the high MCU processing that is required.

The random address resolution is performed by default by the Host whenever the Controller is not able to resolve an RPA. The Host performs random address generation only when Host Privacy is requested to be enabled. During random address generation, the advertising and scan operations, if active, are stopped and restarted. If errors occur during this process and the scan or advertising cannot be started, the application is notified through the corresponding event (gAdvertisingStateChanged_c, gExtAdvertisingStateChanged_c or gScanStateChanged_c)

- **Controller Privacy**, introduced by Bluetooth 4.2, consists of writing the local IRK in the Controller, together with all known peer IRKs, and letting the Controller perform hardware, fully automatic RPA generation and resolution. The Controller uses a Resolving List to store these entries. The size of the list is platform dependent and determined by gMaxResolvingListSize_c. For RPA resolution, the entries that do not fit in this list are processed by the Host to be resolved using the IRKs from Bonded Devices list.

Host Privacy can be enabled at any time. Controller Privacy should only be enabled while the device is not in the advertising, scanning or connection initiating state - otherwise the HCI LE Set Address Resolution Enable command will fail and privacy will not be considered as successfully enabled. Trying to enable one while the other is in progress generates a *gBleInvalidState_c* error. The same error is returned when trying to enable the same privacy type twice, or when trying to disable privacy when it is not enabled.

The recommended way of using Privacy is the Controller Privacy. However, enabling Controller Privacy requires at least a pair of local IRK and peer IRK, so this can only be enabled only after a pairing is performed with a peer and the IRKs are exchanged during the Key Distribution phase. When a device starts, if Privacy is required, the workflow is the following:

1. Enable Host Privacy using the local IRK.
2. Connect to a peer and perform pairing and bonding to exchange IRKs.
3. Disable Host Privacy.
4. Enable Controller Privacy using the local IRK and the peer IRK and peer identity address.

After enabling Host Privacy or Controller Privacy, the application must wait for the gHostPrivacyStateChanged_c or gControllerPrivacyStateChanged_c generic event and verify that privacy has been successfully enabled. Only then it is safe to proceed with setting advertising parameters (via the Gap_SetAdvertisingParameters or Gap_SetExtAdvertisingParameters APIs) or starting scanning (via the Gap_StartScanning API). Failure to do so could result in unwanted behavior, such as the device advertising or scanning with a public address.

Resolvable private addresses A Resolvable Private Address (RPA) is a random address generated using an Identity Resolving Key (IRK). This address appears completely random to an outside observer, so a device may periodically regenerate its RPA to maintain privacy, as there is no correlation between any two different RPAs generated using the same IRK.

On the other hand, an IRK can also be used to resolve an RPA, in other words, to check if this RPA has been generated with this IRK. This process is called “resolving the identity of a device”. Whoever has the IRK of a device can always try to resolve its identity against an RPA.

For example, assume device A frequently changes its RPA using IRKA. At some point, A bonds with B. A must give B a way to recognize it in a subsequent connection when it (A) has a different address. To achieve this purpose, A distributes the IRKA during the Key Distribution phase of the pairing process. B stores the IRKA it received from A.

Later, B connects to a device X that uses RPAX. This address appears completely random, but B can try to resolve RPAX using IRKA. If the resolving operation is successful, it means that IRKA was used to generate RPAX, and since IRKA belongs to device A, it means that X is A. So B was able to recognize the identity of device X, but nobody else can do that since they do not have IRKA.

Parent topic: Introduction

Non-resolvable private addresses A Non-Resolvable Private Address (NRPA) is a completely random address that has no generation pattern and therefore cannot be resolved by a peer.

A device that uses an NRPA that is changed frequently is impossible to track because each new address appears to belong to a new device.

Parent topic: Introduction

Multiple identity resolving keys If a device bonds with multiple peers, all of which are using RPAs, it needs to store the IRK of each in order to be able to recognize them later (see previous section).

This means that whenever the device connects to a peer that uses an unknown RPA, it needs to try and resolve the RPA with each of the stored IRKs. If the number of IRKs is large, then this introduces a lot of computation.

Performing all these resolving operations in the Host can be costly. It is much more efficient to take advantage of hardware acceleration and enable the Controller Privacy.

Parent topic: Introduction

Parent topic: Privacy feature

Host privacy To enable or disable Host Privacy, the following API may be used:

```
bleResult_t Gap_EnableHostPrivacy
(
    bool_t              enable,
    const uint8_t *     aIrk
);
```

When *enable* is set to TRUE, the *aIrk*parameter defines which type of Private Address to generate. If *aIrk* is NULL, then a new NRPA is generated periodically and written into the Controller. Otherwise, an IRK is copied internally from the *aIrk* address and it is used to periodically generate a new RPA.

The lifetime of the Private Address (NRPA or RPA) is a number of seconds contained by the *gGapHostPrivacyTimeout*external constant, which is defined in the *ble_config.c* source file. The default value for this is 900 (15 minutes).

When Host Privacy is enabled, the Host ignores the ownAddressType value for the advertising, scanning or connect parameters. It will always use the random address type in order to use the RPA configured in the Controller in the packets sent over the air.

As mentioned in the Introduction section, call this API for random address generation. For random address resolution there is no need to do so, it is performed by default against the bonded devices list.

Parent topic: Privacy feature

Controller privacy To enable or disable Controller Privacy, the following API may be used:

```
bleResult_t Gap_EnableControllerPrivacy
(
    bool_t                          enable,
    const uint8_t *                   aOwnIrk,
    uint8_t                         peerIdCount,
    const gapIdentityInformation_t*      aPeerIdentities
);
```

When *enable* is set to TRUE, *aOwnIrk*parameter shall not be NULL, *peerIdCount* shall not be zero or greater than *gMaxResolvingListSize_c*, and *aPeerIdentities* shall not be NULL.

The IRK defined by *aOwnIrk* is used by the Controller to periodically generate a new Resolvable Private Address (RPA). The lifetime of the RPA is a number of seconds contained by the *gGapControllerPrivacyTimeout*external constant, which is defined in the *ble_config.c* source file. The default value for this is 900 (15 minutes).

The *aPeerIdentities* is an array of identity information for each bonded device. The identity information contains the device's identity address (public or random static address) and the device's IRK. This array can be obtained from the Host with the *Gap_GetBondedDevicesIdentityInformation*API.

Enabling Controller Privacy involves a quick sequence of commands to the Controller. When the sequence is complete, the *gControllerPrivacyStateChanged_c* generic event is triggered.

Privacy mode In Bluetooth LE 5.0, the privacy mode has been introduced as an optional feature and is part of the GAP identity structure together with the address and address type. There are two modes: Network Privacy Mode (default) and Device Privacy Mode. These are valid only for Controller Privacy.

A device in network privacy mode only accepts packets from peers using private addresses.

A device in device privacy mode also accepts packets from peers using identity addresses, even if the peer had previously distributed the IRK. Private addresses are also accepted.

The privacy mode of a device is stored in NVM together with the IRK with a default value of Network. If the application wants to change this value it can extract the peer identities, modify the privacy mode from network to device and then enable Controller Privacy with the value.

To change the privacy mode of a device and make the change persistent, the user must call the following API:

```
bleResult_t Gap_SetPrivacyMode
(
    uint8_t nvmIndex,
    blePrivacyMode_t privacyMode
);
```

Parent topic: Controller privacy

Scanning and initiating When a Central device is scanning while Controller Privacy is enabled, the Controller actively tries to resolve any RPA contained in the Advertising Address field of advertising packets. If any match is found against the peer IRK list, then the *advertisingAddressResolved* parameter from the scanned device structure is set to TRUE.

In this case, the *addressType* and *aAddress* fields no longer contain the actual Advertising Address as seen over the air, but instead they contain the identity address of the device whose IRK was able to resolve the Advertising Address. In order to connect to this device, these fields shall be used to complete the *peerAddressType* and *peerAddress* fields of the connection request parameter structure, and the *usePeerIdentityAddress* field shall be set to TRUE.

If *advertisingAddressResolved* is equal to FALSE, then the advertiser is using a Public or Random Static Address, an NRPA, or a RPA that could not be resolved. Therefore, the connection to this device is initiated as if Controller Privacy was not enabled, by setting *usePeerIdentityAddress* to FALSE.

Parent topic: Controller privacy

Advertising When a Peripheral starts advertising while Controller Privacy is enabled, the *ownAddressType* field of the advertising parameter structure is unused. Instead, the Controller always generates an RPA and advertises with it as Advertising Address.

If directed advertising is used, the Host only allows advertising to a device in the resolving list in order to be able to generate RPAs.

Parent topic: Controller privacy

Connected When a device connects while Controller Privacy is enabled, the *gConnEvtConnected_c* connection event parameter structure contains more relevant fields than without Controller Privacy.

The *peerRpaResolved* field equals TRUE if the peer was using an RPA that was resolved using an IRK from the list. In that case, the *peerAddressType* and *peerAddress*fields contain the identity address of the resolved device, and the actual RPA used to create the connection (the RPA that a Central used when initiating the connection, or the RPA that the Peripheral advertised with) is contained by the *peerRpa* field.

The *localRpaUsed*field equals TRUE if the local Controller was automatically generating an RPA when the connection was created, and the actual RPA is contained by the *localRpa* field.

Parent topic:*Generic Access Profile (GAP) Layer*

Setting PHY mode in a connection In Bluetooth LE 5.0, the user is able to change the PHY mode in a connection through the Link Layer PHY Update Procedure and choose between default 1 Mbit/s, 2 Mbit/s high data rate or the coded S2 or S8 PHYs with 500 Kbps or 125 Kbps for longer range.

To set the PHY, the user can call:

```
bleResult_t Gap_LeSetPhy
(
    bool_t       defaultMode,
    deviceId_t   deviceId,
    uint8_t      allPhys,
    uint8_t      txPhys,
    uint8_t      rxPhys,
    uint16_t     phyOptions
);
```

There are two modes to use this API:

1. If defaultMode is set to TRUE, the user can call this function without being in a connection, i.e. provide a device ID. The PHY option is used by the Link Layer in the PHY response when a connection is created and the peer device initiates the PHY Update Procedure. The application should listen for gLePhyEvent_c with the gPhySetDefaultComplete_c sub event type for the confirmation of the operation.
2. If defaultMode is set to FALSE, the user must also provide a valid device ID. The Host asks the Link Layer to initiate the PHY Update Procedure with the peer device using the provided parameters.

The application should listen for gLePhyEvent_c with the gPhyUpdateComplete_c sub event type for the confirmation of the update procedure to have ended. The result of the operation populates in the txPhy and rxPhy of the event. The result is from the negotiation of the local parameters and the peer PHY preferences.

To read the current PHY on a connection, call the following API:

```
bleResult_t Gap_LeReadPhy
(
    deviceId_t deviceId
);
```

The application should listen for gLePhyEvent_c with the gPhyRead_c sub event type for the confirmation of the operation. The txPhy and rxPhy indicate the current modes used in the connection.

Parent topic:*Generic Access Profile (GAP) Layer*

Data management of bonded devices The Host handles the management of the bonding data without requiring application intervention. The application must provide the NVM write, read, and erase functions presented in Non-Volatile Memory (NVM) access. The Host creates bonds if bonding is required after the pairing.

The bonded data structure is presented below, together with the GAP APIs that access it, for most APIs require a connection to be established with the device in the bonded list, the others can be accessed any time using the NVM index.

1. Bond Header – identity address and address type that uniquely identify a device together with the IRK and privacy mode.
   - Gap_GetBondedDevicesIdentityInformation – for all bonds
2. Bond Data Dynamic - security counters for signed operations – managed by the stack
3. Bond Data Static – LTK, CSRK, Rand, EDIV, security information for read and write authorizations
   - Gap_SaveKeys– NVM index
   - Gap_LoadKeys– NVM index
   - Gap_LoadEncryptionInformation - deviceId
   - Gap_Authorize – deviceId - GATT Server only
4. Bond Data Legacy - Legacy pair information and CSRK
   - Gap_LoadEncryptionInformation - deviceId
5. Bond Data Device Info - custom peer information (service discovery data) and device name
   - Gap_SaveCustomPeerInformation - deviceId
   - Gap_LoadCustomPeerInformation - deviceId
   - Gap_SaveDeviceName - deviceId
   - Gap_GetBondedDeviceName – NVM index
6. Bond Data Descriptor List - configuration of indications and notifications for CCCD handles – GATT Server only
   - Gap_CheckNotificationStatus - deviceId
   - Gap_CheckIndicationStatus- deviceId

However, there may be some cases when an application wants to manage this data to read data from a bonded device created by the Host, create a bond obtained out-of-band or update an existing bond. For this use case, two GAP APIs and a GAP event have been added.

1. **Load the Keys of a bonded device**.

   The user can call the following function to read the keys exchanged during pairing and stored by the Bluetooth LE Host Stack in the bond area when the pairing is complete.

The application is informed of the NVM index through the gBondCreatedEvent_c sent by the stack immediately after the bond creation. The application is responsible for passing the memory in the pOutKeys OUT parameter to fill in the keys, if any of the keys are set to NULL, the stack does not fill that information. The pOutKeyFlags OUT parameter indicates to the application which of the keys were stored by the stack as not all of them may have been distributed during pairing.

The pOutLeSc indicates if Bluetooth LE 4.2 LE Secure Connections Pairing was used, while the pOutAuth indicates if the peer device is authenticated for MITM protection. All these OUT parameters are recommended to be retrieved from the bond and added if later passed as input parameters for the save keys API.

This function executes synchronously.

```
bleResult_t Gap_LoadKeys
(
    uint8_t             nvmIndex,
    gapSmpKeys_t*       pOutKeys,
    gapSmpKeyFlags_t*   pOutKeyFlags,
    bool_t*             pOutLeSc,
    bool_t*             pOutAuth);
);
```

The gapSmpKeys_t is the structure used during the key distribution phase, as well as in the gConnEvtKeysReceived_c event and is as follows. The difference is that the Bluetooth LE device address cannot be set to NULL neither when loading a bond or when creating one as it identifies the bonded device together with the NVM index.

Table 3. 'gapSmpKeys_t' structure

Event Data	Data type	Data Description
cLtk-Size	uint8_t	Encryption Key Size filled by the stack. If aLtk is NULL, this is ignored.In Advanced Secure Mode, this should be the size of the LTK encrypted blob of 40 bytes.
aLtk	uint8_t*	Long Term (Encryption) Key or LTK encrypted blob if Advanced Secure Mode is enabled. NULL if LTK isnot distributed, else size is given by cLtk-Size
aIrk	uint8_t*	Identity Resolving Key. NULL if aIrk is not distributed.
aCsrk	uint8_t*	Connection Signature Resolving Key. NULL if aCsrk is not distributed.
cRand-Size	uint8_t	Size of RAND filled by the stack; usually equal to gcSmpMaxRandSize_c. IfaLtk is NULL, this is ignored.
aRand	uint8_t*	RAND value used to identify the LTK. If aLtk is NULL, this is ignored.
ediv	uint16_t	EDIV value used to identify the LTK. If aLtk is NULL, this is ignored.
ad-dressTy	bleAd-dress Type_t	Public or Random address.
aAd-dress	uint8_t*	Device Address. It cannot be NULL.

The structure for the GAP SMP Key Flags is the following:

Table 4. GAP SMP Key Flags

Flag Type	Description
gNoKeys_c	No key is available.
gLtk_c	Long-Term Key is available.
gIrk_c	Identity Resolving Key is available.
gCsrk_c	Connection Signature Resolving Key is available.

2. Save the Keys to create a bond or update an existing bonded device.

   The user can call the following function to create a bond on a device based on information obtained Out of Band. For instance, one can use the output of Gap_LoadKeys from the previous section. This can be useful in transferring a bond created by the stack after a pairing procedure or if the application wants to manipulate bonding data. The behavior of the stack remains the same, if the bonding is required after a pairing, the stack stores the bonding information if possible. In this case, the NVM index is passed to the application through gBondCreatedEvent_c.

   This function executes asynchronously, as the stack can create a bond during the execution. The application should listen for the previous mentioned event gBondCreatedEvent_c. The result of the function call is passed synchronously. However, if an asynchronous error has occurred during the actual save, it is passed to the application through the gInternalError_c event with a gSaveKeys_c error source.

   The stack creates a bond if the NVM index is free or update the keys from an NVM index if it stores a valid entry.

   The address from the GAP SMP Keys structure must not be NULL. If other members of the structure are NULL, they are ignored.

   LE SC flag indicates if Bluetooth LE 4.2 Secure Connections was used during pairing and Auth specifies if the peer is authenticated for MITM protection.

```
bleResult_t Gap_SaveKeys
(
    uint8_t         nvmIndex,
    gapSmpKeys_t*   pKeys,
    bool_t          leSc,
    bool_t          auth
);
```

3. Bond created event.

   A GAP event is added to the Bluetooth LE Generic Callback to inform the application of the NVM index whenever the stack creates a bond or when a Gap_SaveKeys request succeeds. The event is also generated if the NVM index was a valid occupied entry and only some of the keys in the bonded information have been updated.

   The NVM index is then used in the GAP APIs to save or load information from the bond.

Event Data	Data type	Data Description
nvmIndex	uint8_t	NVM index for the new created bond
addressType	bleAddressType_t	Public or Random (static) address of the bond
address	bleDeviceAddress_t	Address of the bond

Application removal of bonded devices data The application can remove a bonded device from NVM. The bonded device cannot be deleted if it is in an active connection. The application can remove one or all bonds by calling the following synchronous GAP APIs:

- Gap_RemoveBond(uint8_t nvmIndex) – nvmIndex can be obtained via the Gap_CheckIfBonded API.
- Gap_RemoveAllBonds() - no connections should be active otherwise the call fails.

Removing a bonded device does not affect the controller address resolution state nor the contents of either the Controller Filter Accept List or the Controller Resolving List. If Controller Privacy is enabled, it remains so until it is disabled or the device is reset.

In a scenario where the user wants to remove a bonded device and all its effects on device behavior (Controller Filter Accept List, Controller Resolving List), the following operations should be executed:

- Gap_ClearFilterAcceptList or Gap_RemoveDeviceFromFilterAcceptList
  - Clear Controller Filter Accept List or clear a device from Filter Accept List.
- Gap_RemoveAllBonds or Gap_RemoveBond
  - All bonded devices are removed or one bonded device is removed from NVM.
- BleConnManager_DisablePrivacy
  - Controller Privacy is disabled, Controller Resolving List is cleared and address resolution is disabled. The device should not be advertising or scanning, otherwise this call fails.
- BleConnManager_EnablePrivacy
  - Called after the gControllerPrivacyStateChanged_c event is received, confirming Controller Privacy has been disabled. If not all bonds have been deleted, Controller Privacy is reenabled. In the absence of bonds, Host Privacy is enabled.

Parent topic: Data management of bonded devices

Parent topic:*Generic Access Profile (GAP) Layer*

Controller enhanced notifications This section describes how the application can configure and monitor the notifications generated by the Bluetooth Controller when advertising, scan, or connection events occur. This feature is proprietary to NXP that is available on selected Controllers.

The user can choose between two options:

1. Enable notifications from the GAP layer and monitor GAP events in the GAP Generic Callback. The controller issues HCI vendor-specific events processed by the Bluetooth LE Host and presented to the application in the GAP Generic Callback.
2. Enable notifications from the Controller interface and monitor controller events in a user-defined Application Callback.
3. Combination of the above two options: configure feature at GAP layer and install an Application Callback through the Controller interface. After setting the callback, the HCI vendor-specific events are not issued and implicitly the GAP events. Instead, the user receives the notifications in the installed callback until setting the callback to NULL again if it wants to revert to GAP events.

- **GAP configuration:**

  The user should call the following function to enable various events from the mask or use Event None to disable the feature. The Device ID is valid only for connection events.

```
bleResult_t Gap_ControllerEnhancedNotification
(    uint16_t eventType,
   deviceId_t deviceId
);
```

  The event type is a bitmask having the following options:
  Table 5. Event types and their description

Event Type	Event Description
gNotifEventNone_c	No enhanced notification event enabled
gNotifConnEventOver_c	Connection event over
gNotifConnRxPdu_c	Connection RX PDU
gNotifAdvEventOver_c	Advertising event over
gNotifAdvTx_c	Advertising ADV transmitted
gNotifAdvScanReqRx_c	Advertising SCAN REQ RX
gNotifAdvConnReqRx_c	Advertising CONN REQ RX
gNotifScanEventOver_c	Scanning event over
gNotifScanAdvPktRx_c	Scanning ADV PKT RX
gNotifScanRspRx_c	Scanning SCAN RSP RX
gNotifScanReqTx_c	Scanning SCAN REQ TX
gNotifConnCreated_c	Connection created
gNotifChannelMatrix_c	Enable channel status monitoring
gNotifPhyReq_c	Phy Req Pdu ack received
gNotifConnChannelMapUpdate_c	Channel map update
gNotifConnInd_c	Connect indication
gNotifPhyUpdateInd_c	Phy update indication

After enabling events, the user should wait for a gControllerNotificationEvent_c GAP Generic Event in the GAP Generic Callback. The first event received should have the event type set to gNotifEventNone_c with a status of success confirming the selected event mask has been enabled. The same event types apply for both the GAP command and the GAP event. The structure for the Controller Notification event is the following:

Table 6. Controller Notification Event structure

Event Data	Data type	Data Description
event-Type	bleNotification-Event_t	Enhanced notification event type
devi-ceId	deviceId_t	Device id of the peer, valid for connection events
rssi	int8_t	RSSI, valid for RX event types
channel	uint8_t	Channel, valid for connection event over or Rx/Tx events
ce_counte	uint16_t	Connection event counter, valid for connection events only
status	bleResult_t	Status of the request to select which events to be enabled/disabled
times-tamp	uint16_t	Timestamp in 625 µs slots, valid for Conn RX event and Conn Created event
adv_hand	uint8_t	Advertising Handle, valid for advertising events, if multiple ADV sets supported

- **Controller configuration:**

  The user should call the following function to enable various events from the mask or use Event None to disable the feature. The same event types apply as the GAP layer types. The connection handle is valid only for connection events.

```
bleResult_t Controller_ConfigureEnhancedNotification
(
    uint16_t eventType,
    uint16_t conn_handle
);
```

The event monitoring is done in a user-installed callback by calling:

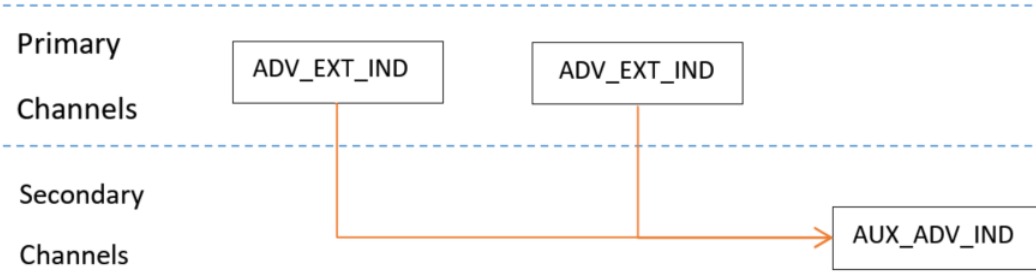
```
bleResult_t Controller_RegisterEnhancedEventCallback
(
    bleCtrlNotificationCallback_t notificationCallback
);
```

Where the types are the following:

```
typedef struct bleCtrlNotificationEvent_tag
{
    uint16_t event_type; /*! bleNotificationEventType_t */
    uint16_t conn_handle;
    uint8_t  rssi;
    uint8_t  channel_index;
    uint16_t conn_ev_counter;
    uint16_t timestamp;
    uint8_t  adv_handle;
} bleCtrlNotificationEvent_t;
typedef void (*bleCtrlNotificationCallback_t)
(
    bleCtrlNotificationEvent_t     *pNotificationEvent
);
```

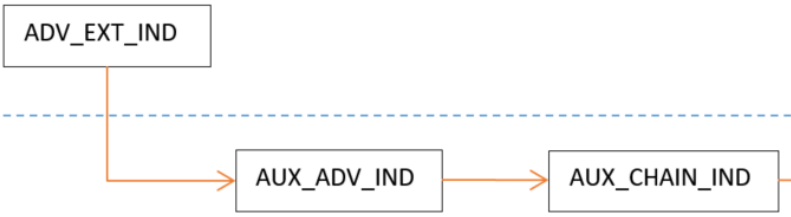
The event structure is nearly identical as the GAP one, except there is no status as the function call executes synchronously.

Table 7. 'bleCtrlNotificationEvent_tag' Event structure



Event Data	Data type	Data Description
event_type	bleNotificationEvent_t	Enhanced notification event type
conn_handle	uint16_t	Connection handle of the peer, valid for connection events
rssi	int8_t	RSSI, valid for RX event types
channel_index	uint8_t	Channel, valid for connection event over or Rx/Tx events
conn_ev_cou	uint16_t	Connection event counter, valid for connection events only
timestamp	uint16_t	Timestamp in 625 µs slots, valid for Conn RX event and Conn Created event
adv_handle	uint8_t	Advertising Handle, valid for advertising events, if multiple ADV sets supported

Parent topic:*Generic Access Profile (GAP) Layer*



Extended advertising Starting with Bluetooth 5, the advertising channels are separated in primary advertising channels and secondary advertising channels:

1. Primary advertising channels
   - Use 3 legacy advertising channels 37, 38, and 39.
   - Can use either legacy 1M PHY or new LE Coded PHY.
   - PHY payload can vary from 6 to 37 bytes.
   - Packets on these channels are part of the advertising events.
2. Secondary advertising channels
   - Use 37 channels, with the same channel index as the data channels.
   - Can use any LE PHY, but the same PHY during an Extended Advertising Event.

- PHY payload can vary from 0 to 255 bytes.
- Auxiliary packets on these channels are part of the Extended Advertising Event that begins at the same time with the advertising event on primary channel and ends with the last packet on the secondary channel.

Extended advertising

Extended advertising – Multiple chains

An advertising data set is represented by advertising PDUs belonging together in an advertising event. Each set has different advertising parameters: PDU type, advertising interval, and PHY mode. The advertising data sets are identified by the Advertising SID (Set ID) field from the ADI – Advertising Data Info. Advertising data or Scan response data can be changed for each adverting data set and the random value of DID (Data ID) field is updated to differentiate between them.

Refer to Figure 1 and Figure 2.

Peripheral setup This section describes the extended advertising GAP API. The application should not use both the extended and legacy API Refer to Scanning. If this requirement cannot be met, the application should at least wait for the generated events in the Advertising Callback prior to using the other API. That is, it is advisable to call legacy functions only after the event pertaining to an extended API is received, and vice versa. This GAP constraint can be considered an extension of the HCI constraint from the Bluetooth 5 specification: “A Host should not issue legacy commands to a Controller that supports the LE Feature (Extended Advertising)”.

The application configures extended advertising by going through the following states:

1. Set the extended advertising parameters by calling:

```
bleResult_t Gap_SetExtAdvertisingParameters
(
gapExtAdvertisingParameters_t* pAdvertisingParameters
);
```

It may use the default set of parameters *gGapDefaultExtAdvertisingParameters_d*. The application should wait for a *gExtAdvertisingParametersSetupComplete_c event* in the Generic Callback. Only one advertising set can be configured at a time. Comparing with the legacy *Gap_SetAdvertisingParameters* command, the new set of parameters is as follows.

Parameter	Description
SID	Value of the Advertising SID subfield in the ADI field of the PDU.
handle	Used to identify an advertising set. Possible values are 0x00 or 0x01 since the current implementation supports two advertising sets.
extAdvProperties	BIT0 - Connectable advertising
extAdvProperties	BIT1 - Scannable advertising
extAdvProperties	BIT2 - Directed advertising
extAdvProperties	BIT3 - High Duty Cycle Directed Connectable advertising (≤3.75 ms Advertising Interval)
extAdvProperties	BIT4 - Use legacy advertising PDUs
extAdvProperties	BIT5 - Omit advertiser's address from all PDUs ("anonymous advertising")
extAdvProperties	BIT6 - Include TxPower in the extended header of the advertising PDU. If legacy advertising PDU types are being used (BIT4 = 1), permitted properties values are presented in the next table. If the advertising set already contains data, the type shall be one that supports advertising data and the amount of data shall not exceed 31 octets. If extended advertising PDU types are being used (BIT4 =0), then the advertisement shall not be both connectable and scannable. While high duty cycle directed connectable advertising (≤ 3.75 ms advertising interval) shall not be used (BIT3 = 0).
txPowe	Maximum power level at which the advertising packets are to be transmitted, the Controller can choose any power level <= txPower. Value 127 to be used if Host has no preference.
primaryPHY	PHY for ADV_EXT_IND: LE 1 M or LE Coded
secondaPHY	PHY for AUX_ADV_IND and periodic advertising: LE 1 M, LE 2 M or LE Coded. Ignored for legacy advertising
secondaMaxS	Maximum advertising events that the Controller can skip before sending the AUX_ADV_IND packets on the secondary advertising channel. Higher values may result in lower power consumption. Ignored for legacy advertising
enableScanReqNotifi-	Whether to enable notifications when scanning PDUs (SCAN_REQ, AUX_SCAN_REQ) are received. If enabled, the application is notified upon scan requests by gExtScanNotification_c events in the Advertising Callback

When using LE Coded PHY for advertising, the default coding scheme chosen by link layer is S=8 (125 kb/s data rate). To change the default coding scheme, the user has two options:

- At compile time by defining *mLongRangeAdvCodingScheme_c*, or
- At run time by calling the API *Controller_ConfigureAdvCodingScheme()*. In both cases, the value of the define or the parameter of the API has to be an appropriate value for primary and secondary PHYs as defined by the enumeration *advCodingScheme_tag* found in *controller_interface.h*. **API Controller_ConfigureAdvCodingScheme()**

EventType	PDU Type	Advertising Event Properties
Connectable and scannable undirected	ADV_IND	00010011b
Connectable directed (low duty cycle)	ADV_DIRECT_IND	00010101b
Connectable directed (high duty cycle)	ADV_DIRECT_IND	00011101b
Scannable undirected	ADV_SCAN_IND	00010010b
Non-connectable and Nonscannable undirected	ADV_NONCONN_INI	00010000b

2. Set the advertising data and/or scan response data by calling:

```
bleResult_t Gap_SetExtAdvertisingData
(
uint8_t handle,
gapAdvertisingData_t* pAdvertisingData,
gapScanResponseData_t* pScanResponseData
);
```

Note: Either of the pAdvertisingData or pScanResponseData parameters can be NULL, but not both. For extended advertising (BIT4 = 0) only one must be different than NULL – the scannable advertising bit (BIT1) indicates whether pAdvertisingData (BIT1 = 0) orpScanResponseData (BIT1 = 1) is accepted. The total amount of Advertising Data shall not exceed 1650 bytes. Application should wait for a *gExtAdvertisingDataSetupComplete_c* event in the Generic Callback.

3. Enable extended advertising by calling:

```
bleResult_t Gap_StartExtAdvertising
(
gapAdvertisingCallback_t advertisingCallback,
gapConnectionCallback_t connectionCallback,
uint8_t handle,
uint16_t duration,
uint8_t maxExtAdvEvents
);
```

When using the common application structure, the application can use the following API defined in *app_conn.h*:

```
bleResult_t BluetoothLEHost_StartExtAdvertising
(
    appExtAdvertisingParams_t *pExtAdvParams,
    gapAdvertisingCallback_t  pfAdvertisingCallback,
    gapConnectionCallback_t   pfConnectionCallback
);
```

The API goes through the steps of setting the advertising data and parameters. Events from the Host task are treated in the *App_AdvertiserHandler()* function, implemented in *app_advertiser.c*. To set the extended advertising parameters and data *BluetoothLEHost_StartExtAdvertising* a parameter of the following type:

```
typedef struct appExtAdvertisingParams_tag
{
    gapExtAdvertisingParameters_t *pGapExtAdvParams;
    gapAdvertisingData_t *pGapAdvData;
    gapScanResponseData_t *pScanResponseData;
    uint8_t                handle;
    uint16_t               duration;
    uint8_t                maxExtAdvEvents;
} appExtAdvertisingParams_t;
```

Advertising may be enabled for each previously configured advertising set, identified by the handle parameter. If duration is set to 0, advertising continues until the Host disables it, otherwise advertising is only enabled for this period (multiple of 10 ms). *maxExtAdvEvents* represent the maximum number of extended advertising events the Controller shall attempt to send prior to terminating the extended advertising, ignored if set to 0. Application should wait for a *gExtAdvertisingStateChanged_c* or a *gAdvertisingCommandFailed_c* event in the Advertising Callback.

4. Disable advertising by calling:

```
bleResult_t Gap_StopExtAdvertising
(
uint8_t handle
);
```

Application should wait for a *gExtAdvertisingStateChanged_c* or a *gAdvertisingCommandFailed_c* event in the Advertising Callback.

5. Remove the advertising set by calling:

```
bleResult_t Gap_RemoveAdvSet
(
uint8_t handle
);
```

Application should wait for a *gExtAdvertisingSetRemoveComplete_c* event in the Generic Callback.

Parent topic: Extended advertising

Central setup The application configures the extended scanning by going through the following states:

1. Start scanning by calling:

```
bleResult_t Gap_StartScanning
(
const gapScanningParameters_t* pScanningParameters,
gapScanningCallback_t scanningCallback,
gapFilterDuplicates_t enableFilterDuplicates,
uint16_t duration,
uint16_t period
)
```

When using the common application structure, the application can use the following API defined in *app_conn.h*:

```
bleResult_t BluetoothLEHost_StartScanning
(
    appScanningParams_t   *pAppScanParams,
    gapScanningCallback_t pfCallback
);
```

The API starts scanning using the given parameters, which must have the following structure:

```
typedef struct appScanningParams_tag
{
    gapScanningParameters_t *pHostScanParams;        /*!< Pointer to host scan structure */
    gapFilterDuplicates_t enableDuplicateFiltering;  /*!< Duplicate filtering mode */
    uint16_t duration;                                    /*!< scan duration  */
    uint16_t period;                                      /*!< scan period  */
} appScanningParams_t;
```

Application may use the default set of parameters *gGapDefaultExtScanningParameters_d*. If the *pScanningParameters* pointer is NULL, the latest set of parameters are used. The *scanningPHYs* parameter indicates the PHYs on which the advertising packets should be received on the primary advertising channel. As a result, permitted values for the parameter are 0x01 (scan LE 1M), 0x04 (scan LE Coded) and 0x05 (scan both LE 1M and LE Coded). There are no strict timing rules for scanning, yet if both PHYs are enabled for scanning, the scan interval value must be large enough to accommodate two scan windows (interval >= 2 * window).

If the advertiser uses legacy advertising PDUs, the device may actively scan by sending a SCAN_REQ PDU to the advertiser on the LE 1M primary advertising channel (no secondary channel in legacy advertising). Respectively, if the advertiser uses extended advertising PDUs, the active scan operation takes place on the secondary advertising channel. After the device receives a scannable ADV_EXT_IND PDU on the primary advertising channel (PHY LE 1M or Coded), it starts listening for the AUX_ADV_IND PDU on the secondary advertising channel (PHY 1M, 2M or Coded). Once received, the device sends an AUX_SCAN_REQ to the advertiser. Next, an AUX_SCAN_RSP PDU should be received, containing the scan response data. Application should wait for a *gScanStateChanged_c* or a *gScanCommandFailed_c*in the Scanning Callback.

2. Collect information by waiting for *gDeviceScanned_c* (legacy advertising PDUs) or *gExtDeviceScanned_c* (extended advertising PDUs) event in the Scanning Callback. The *gExtDeviceScanned_c* event contains additional information pertaining to the extended received PDU, such as: primary PHY, secondary PHY, advertising SID, interval of the periodic advertising if enabled in the set.

   When using the common application structure, the application can use the following API defined in *app_conn.h*, to search the contents from *pData* in an advertising element:

   ```
   bool_t BluetoothLEHost_MatchDataInAdvElementList
   (
       gapAdStructure_t *pElement,
       void             *pData,
       uint8_t          iDataLen
   );
   ```

3. Stop scanning by calling the function below:

   ```
   bleResult_t Gap_StopScanning(void);
   ```

   Application should wait for a *gScanStateChanged_c* or a *gScanCommandFailed_c* in the Scanning Callback.

4. Connect to a device by calling the function below:

   ```
   bleResult_t Gap_Connect
   (
   const gapConnectionRequestParameters_t* pParameters,
   gapConnectionCallback_t connCallback
   );
   ```

   When using the common application structure, the following API can be used:

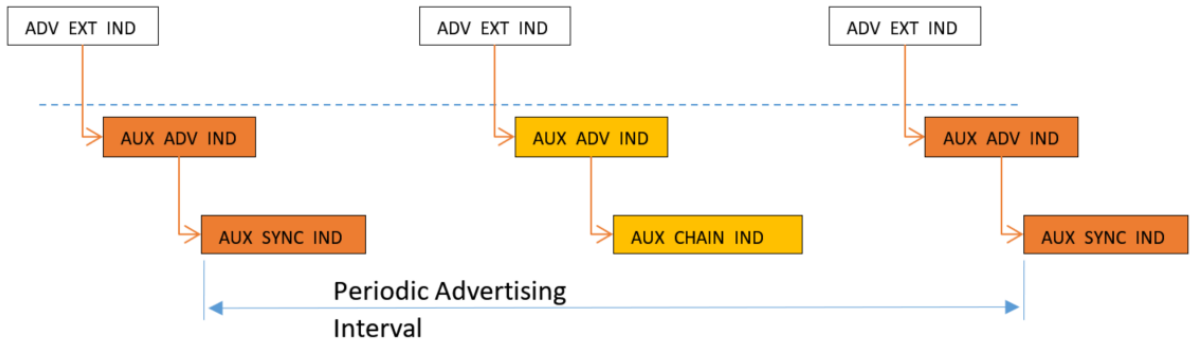
```
bleResult_t BluetoothLEHost_Connect
(
    gapConnectionRequestParameters_t*    pParameters,
    gapConnectionCallback_t              connCallback
);
```

The *initiatingPHYs* parameter indicates the PHYs on which the advertising packets should be received on the primary advertising channel and the PHYs for which connection parameters have been specified. The parameter is a bitmask of PHYs: BIT0 = LE 1M, BIT1 = LE 2M and BIT2 = LE Coded. The Host may enable one or more initiating PHYs, but it must at least set one bit for a PHY allowed for scanning on the primary advertising channel, i.e., BIT0 for LE 1M PHY or BIT2 for LE Coded PHY.

If the advertiser uses legacy advertising PDUs, the device may connect by sending a CONNECT_IND PDU to the advertiser on the LE 1M primary advertising channel (no secondary channel in legacy advertising). On the other hand, if the advertiser uses extended advertising PDUs, the extended connect operation takes place on the secondary advertising channel. After the device receives a connectable ADV_EXT_IND PDU on the primary advertising channel (PHY LE 1M or Coded), it starts listening for the connectable AUX_ADV_IND PDU on the secondary advertising channel (PHY 1M, 2M or Coded). Once received, the device sends an AUX_CONNECT_REQ to the advertiser. Next, if AUX_CONNECT_RSP PDU is received, the device enters the Connection State in the Central role on the secondary advertising channel PHY.

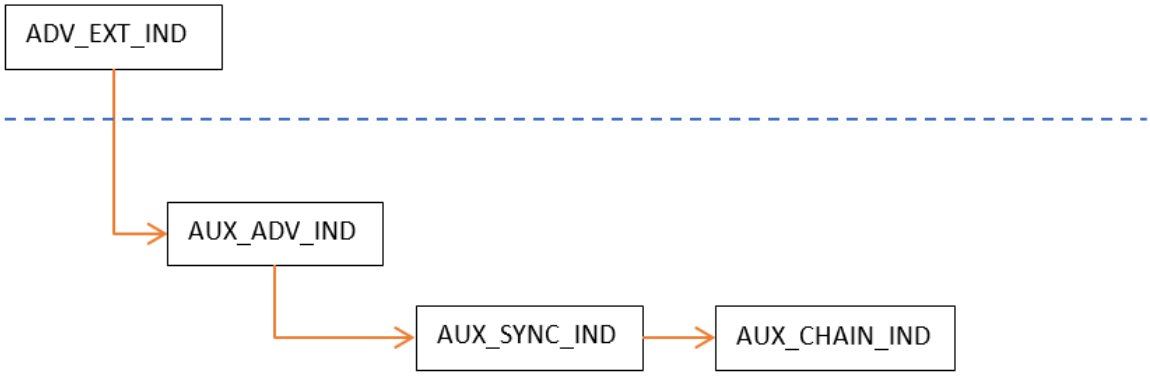
Application should wait for a *gConnEvtConnected_c* event in the Connection Callback. If the channel selection algorithm #2 is used for this connection, then a *gConnEvtChanSelectionAlgorithm2_c* event is also generated.

After the connection is successfully established, the application may choose to read the connection PHY by calling the *Gap_LeReadPhy* API. It may also opt to change the PHY of the connection by triggering a PHY Update Procedure using the *Gap_LeSetPhy API*. However, the Controller might not be able to perform the change if, in case the peer does not support the new requested PHY.



Parent topic: Extended advertising

Parent topic:*Generic Access Profile (GAP) Layer*



Periodic Advertising Periodic channels are used for periodic broadcast between unconnected devices. A periodic channel is represented by a channel map and a set of hopping and timing parameters.

The set of channels is represented by the 37 data channels. A packet sent by an advertiser can also have a payload of up to 255 bytes and it can be sent on any LE PHY. Figure 1 and Figure 2.

Extended Advertising and Periodic Advertising combined

Periodic Advertising – Multiple chains

Peripheral Setup

1. First set the extended advertising parameters using Gap_SetExtAdvertisingParameters. The extended advertising type must be set to non-connectable and non-scannable.
2. Set the periodic advertising parameters using the same handle as in the previous command.

```
bleResult_t Gap_SetPeriodicAdvParameters
(
    gapPeriodicAdvParameters_t*     pAdvertisingParameters
);
```

   Wait for a *gPeriodicAdvParamSetupComplete_c*event in the generic callback.

3. Next, set the periodic advertising data by calling:

```
bleResult_t Gap_SetPeriodicAdvertisingData
(
    uint8_t                     handle,
    gapAdvertisingData_t*   pAdvertisingData,
    bool_t bUpdateDID
);
```

   pAdvertisingData cannot be NULL. If periodic advertising data must be empty, set *cNumAdStructures* to 0. Wait for a *gPeriodicAdvDataSetupComplete_c*event in the generic callback.

4. Start extended advertising using Gap_StartExtAdvertising.
5. Last, enable Periodic Advertising. Periodic advertising starts only after extended advertising is started.

```
bleResult_t Gap_StartPeriodicAdvertising
(
    uint8_t handle,
    bool_t  bIncludeADI
);
```

   Wait for a *gPeriodicAdvertisingStateChanged_c*event in the advertising callback.

Parent topic: Periodic Advertising

Central Setup

The application may decide to listen to periodic advertising by going through the following states:

1. [Optional] Add a known periodic advertiser to the periodic advertiser list held in the Controller by calling:

```
bleResult_t Gap_UpdatePeriodicAdvList
(
    gapPeriodicAdvListOperation_t operation,
    bleAddressType_t              addrType,
    uint8_t*                      pAddr,
    uint8_t                       SID
);
```

Wait for the *gPeriodicAdvListUpdateComplete_c* event in the Generic Callback.

2. Synchronize with a periodic advertiser by calling:

```
bleResult_t Gap_PeriodicAdvCreateSync
(
    gapPeriodicAdvSyncReq_t*    pReq,
);
```

pReq parameter *filterPolicy*can be set to *gUseCommandParameters_c* to synchronize with the given peer, or to *gUsePeriodicAdvList_c* to start synchronizing with all the devices in the previously populated periodic advertiser list.

Wait for the *gPeriodicAdvSyncEstablished_c* event and check the status. If scanning is not enabled at the time this command is sent, synchronization occurs after scanning is started. Synchronization remains pending until *gPeriodicAdvSyncEstablished_c*event is received. If synchronization was successful, the *syncHandle* is returned in this event.

3. Terminate the synchronization with the periodic advertiser by calling:

```
bleResult_t Gap_PeriodicAdvTerminateSync
(
    uint16_t syncHandle
);
```

To cancel a pending synchronization, the application should call *Gap_PeriodicAdvTerminateSync* with *syncHandle* set to the reserved value *gBlePeriodicAdvOngoingSyncCancelHandle* and wait for *gPeriodicAdvCreateSyncCancelled_c* event.

Otherwise, to terminate an already established sync with an advertiser, use the *syncHandle* value from the *gPeriodicAdvSyncEstablished_c* event and wait for a *gPeriodicAdvSyncTerminated_c* event.

Parent topic: Periodic Advertising

Parent topic:*Generic Access Profile (GAP) Layer*

Periodic Advertising with Responses (PAwR) This section describes the Central and Peripheral setup for Periodic Advertising with Responses (PAwR).

Central Setup

1. Start scanning using Gap_StartScanning. Wait for gPeriodicDeviceScannedV2_c events in the scanning callback.
2. Synchronize with a periodic advertiser by calling Gap_PeriodicAdvCreateSync. Wait for the gPeriodicAdvSyncEstablished_c event in the scanning callback. When PAwR is involved, this event includes additional information such as number of subevents, subevent interval, response slot delay and spacing,
3. Synchronize to a PAwR subevent by calling Gap_SetPeriodicSyncSubevent. This API instructs the Controller to sync with a subset of the subevents within a PAwR train identified by syncHandle (obtained after synchronizing with the PAwR train in the previous step).

```
bleResult_t Gap_SetPeriodicSyncSubevent ( uint16_t syncHandle, const␣
↪gapPeriodicSyncSubeventParameters_t* pParams );
```

Wait for the gPeriodicSyncSubeventComplete_c event.

4. Use Gap_SetPeriodicAdvResponseData to set data in the AD format which would be sent as a Periodic Advertising Response to the broadcaster.

```
bleResult_t Gap_SetPeriodicAdvResponseData ( uint16_t syncHandle, const␣
↪gapPeriodicAdvertisingResponseData_t* pData );
```

5. Optionally, the periodic advertiser may initiate a connection. If no connection callback was set on the scanner via APIs such as Gap_Connect or Gap_StartAdvertising/ Gap_StartExtAdvertising, one must be explicitly set. This is achieved by calling BluetoothLEHost_SetConnectionCallback (defined in app_conn.h), which in turn calls Gap_SetConnectionCallback.

```
void Gap_SetConnectionCallback ( gapConnectionCallback_t pfConnectionCallback );
```

Parent topic: Periodic Advertising with Responses (PAwR)

Peripheral Setup

1. First set the extended advertising parameters using Gap_SetExtAdvertisingParameters. The extended advertising type must be set to non-connectable and non-scannable.
2. Set the periodic advertising parameters with the same handle as in the previous command. Use the Gap_SetPeriodicAdvParametersV2 command. Compared to Gap_SetPeriodicAdvParameters, this command also configures parameters relevant to PAwR, such as the number of subevents and response slots as well as timing information.

```
bleResult_t Gap_SetPeriodicAdvParametersV2
  (gapPeriodicAdvParametersV2_t* pAdvertisingParameters);
```

Wait for a gPeriodicAdvParamSetupComplete_c event in the generic callback.

3. Start extended advertising using Gap_StartExtAdvertising.
4. Start periodic advertising using Gap_StartPeriodicAdvertising.
5. Wait for gPerAdvSubeventDataRequest_c events. These events are used by the Controller to indicate that it is ready to transmit one or more subevents and it is requesting the advertising data for these subevents. Upon receiving an event, use Gap_SetPeriodicAdvSubeventData to set the advertising data for specific subevents.

```
bleResult_t Gap_SetPeriodicAdvSubeventData
    (uint8_t advHandle, const gapPeriodicAdvertisingSubeventData_t* pData);
```

Wait for the gPeriodicAdvSetSubeventDataComplete_c event in the generic callback.

6. Wait for gPerAdvResponse_c events. These events contain responses sent by devices who are synchronized to the periodic advertising. They include data in the AD format.
7. Optionally, PAwR allows the advertising device to initiate a connection to one of the synchronized scanners. The connection can be initiated by calling Gap_ConnectFromPawr.

```
bleResult_t Gap_ConnectFromPawr
    (const gapConnectionFromPawrParameters_t* pParameters, gapConnectionCallback_t connCallback);
```

Parent topic: Periodic Advertising with Responses (PAwR)

Parent topic:*Generic Access Profile (GAP) Layer*

Encrypted Advertising Data This section describes the Central and Peripheral setup for encrypted advertising data.

Central Setup Use the Gap_DecryptAdvertisingData API to decrypt the contents of "Encrypted Advertising Data" (0x31) AD types included in scanned data.

```
bleResult_t Gap_DecryptAdvertisingData
    (uint8_t *pData, uint16_t dataLength, const uint8_t *pKey, const uint8_t *pIV, uint8_t *pOutput)
```

Parent topic: Encrypted Advertising Data

Peripheral Setup Use the Gap_EncryptAdvertisingData API to obtain the encrypted advertising data, which can then be placed inside the "Encrypted Advertising Data" (0x31) AD type.

```
bleResult_t Gap_EncryptAdvertisingData
  ( const gapAdvertisingData_t *pAdvertisingData, const uint8_t *pKey, const uint8_t *pIV, uint8_t␣
↪*pOutput )
```

Parent topic: Encrypted Advertising Data

Parent topic:*Generic Access Profile (GAP) Layer*

L2CAP credit-based channels The L2CAP layer, which is responsible for protocol multiplexing, segmentation, and reassembly operations, allows devices to communicate via connection-oriented channels. These channels use credit-based flow control, in which a device grants each peer a number of credits which the peer can use to send packets. The number of credits is decremented with every sent packet. A device can grant more credits to its peers over the duration of the connection.

Unlike the fixed L2CAP CIDs used by protocols such as ATT and SMP, credit-based channels use dynamically allocated CIDS (in the 0x0040-0xFFFF range). The CIDs are automatically allocated by the Bluetooth LE Host Stack.

The Bluetooth LE Host Stack supports both the Credit-based Flow Control Mode and the Enhanced Credit-based Flow Control Mode. In the Enhanced Credit-based Flow Control Mode, devices can open up to five channels in a single connect request/response exchange. Additionally, these channels can be later reconfigured with new MTU and MPS values. In the Credit-based Flow Control Mode, reconfiguration is not possible.

The first thing an application must do is register the control and data callbacks:

```
bleResult_t   L2ca_RegisterLeCbCallbacks
(
   l2caLeCbDataCallback_t      pCallback,
   l2caLeCbControlCallback_t   pCtrlCallback
);
```

The control callback receives events related to channel management such as connection, disconnection, received credits, reconfiguration, and so on.

The data callback receives the data which is being exchanged on the channel.

To use L2CAP credit-based channels, the application must register a PSM. The PSM is analogous to a TCP/UDP port. It is an identifier used to determine the upper layer protocol which is making use of the L2CAP channel. The dynamic PSM range is 0x0080-0x00FF. The number of PSMs supported by an application can be configured at compile time via the gL2caMaxLePsmSupported_c define. The following API must be called in order to register a PSM:

```
bleResult_t  L2ca_RegisterLePsm
(
  uint16_t     lePsm,
  uint16_t     lePsmMtu
);
```

The MTU configured via this API is used by every channel opened under the PSM, if the Credit-based Flow Control Mode is used. The minimum MTU is 23 and the maximum MTU is 65535.

When the Enhanced Credit-based Flow Control Mode is used, the MTU is specified at each connection request. In this mode, the minimum MTU is 64 and the maximum MTU is 65535.

The local MPS is not configurable by the application. It is set automatically by the Host Stack based on Controller capabilities. Usually, it will be 247.

A previously registered PSM can be deregistered:

```
bleResult_t L2ca_DeregisterLePsm
(
 uint16_t     lePsm
);
```

The number of credit-based channels that can be opened is configurable by the application via the gL2caMaxLeCbChannels_c define. This is the total number for all peers. To open a channel, the following API must be called:

```
bleResult_t L2ca_ConnectLePsm
(
  uint16_t     lePsm,
  deviceId_t   deviceId,
  uint16_t     initialCredits
);
```

To open up to five channels using Enhanced Credit-based Flow Control Mode, use this API:

```
bleResult_t  L2ca_EnhancedConnectLePsm
(
 uint16_t     lePsm,
 deviceId_t   deviceId,
 uint16_t     mtu,
 uint16_t     initialCredits,
 uint16_t     initialCredits,
 uint16_t     *aCids
);
```

The connect APIs must be called by both the initiator and the responder (upon receiving the gL2ca_LePsmConnectRequest_c or gL2ca_LePsmEnhancedConnectRequest_c events in the application).

If the responder does not wish to accept the connection request, it can use the following APIs:

```
bleResult_t  L2ca_CancelConnection
   (
     uint16_t       lePsm,
     deviceId_t     deviceId,
    l2caLeCbConnectionRequestResult_t refuseReason
   );
bleResult_t L2ca_EnhancedCancelConnection
   (
   uint16_t lePsm,
   deviceId_t deviceId,
   l2caLeCbConnectionRequestResult_t refuseReason,
```

(continues on next page)

(continued from previous page)

```
    uint8_t noOfChannels,
    uint16_t *aCids
    );
```

When a channel has been successfully established, the gL2ca_LePsmConnectionComplete_c or gL2ca_LePsmEnhancedConnectionComplete_c events are received in the application.

To send data on a channel:

```
bleResult_t L2ca_SendLeCbData
(
  deviceId_t      deviceId,
  uint16_t        channelId,
  const uint8_t*  pPacket,
  uint16_t        packetLength
);
```

The Host Stack keeps track of the credits granted to peers for each channel and decrements them accordingly. When a peer's credit count reaches zero, the application is notified through the gL2ca_NoPeerCredits_c event and it can decide to send more credits to the peer for that channel:

```
bleResult_t L2ca_SendLeCredit
(
 deviceId_t     deviceId,
 uint16_t       channelId,
 uint16_t       credits
);
```

The application can also choose to be notified when the number of credits allocated to a peer for a certain channel is nearing 0, by setting the gL2caLowPeerCreditsThreshold_c macro to a non-zero value. When this limit is reached, the gL2ca_LowPeerCredits_c event is received and the application can choose to send more credits.

Similarly, when a device receives credits from a peer, the application is notified through the gL2ca_LocalCreditsNotification_c event. When the local device has used its last credit, it receives the same gL2ca_LocalCreditsNotification_c event with the localCredits field set to 0. The packet that could not be sent due to exhausting the credits remains queued in the Host Stack and it is sent automatically when the local device receives credits from the peer.

To improve application flow control, two notification-type events are implemented by the Host Stack:

- gL2ca_ChannelStatusChannelBusy_c
- gL2ca_ChannelStatusChannelIdle_c

When the application sends a packet using L2ca_SendLeCbData, it receives a gL2ca_ChannelStatusChannelBusy_c event in the L2CAP control callback when the Host Stack begins sending the packet. When the Host Stack has sent the packet, a gL2ca_ChannelStatusChannelIdle_c event is received. The application can choose to use this event as a signal that it is safe to send the next packet.

To disconnect a channel:

```
bleResult_t L2ca_DisconnectLeCbChannel
(
   deviceId_t  deviceId,
   uint16_t    channelId
);
```

As mentioned previously, channels which use the Enhanced Credit-based Flow Control Mode can be reconfigured. This is achieved via the API:

```
bleResult_t L2ca_EnhancedChannelReconfigure
(
    deviceId_t      deviceId,
    uint16_t        newMtu,
    uint16_t        newMps,
    uint8_t         noOfChannels,
    uint16_t        *aCids
);
```

The reconfiguration request is automatically accepted by the Host Stack if parameters are valid (as per the Bluetooth Core Spec v5.3, MTU cannot be lowered and MPS cannot be lowered for more than one channel). On the responder, the gL2ca_EnhancedReconfigureRequest_c is received by the application in case of a successful reconfiguration, informing it of the new channel parameters. On the initiator, the gL2ca_EnhancedReconfigureResponse_c is received, informing the application about the received response or a timeout.

Parent topic:*Generic Access Profile (GAP) Layer*

Enhanced ATT The Enhanced ATT protocol allows concurrent transactions to be handled by the stack. The sequential transaction rule still exists when EATT is used, but its scope is now defined as being per instance of the Enhanced ATT Bearer. EATT transactions might execute in parallel if they are supported by distinct L2CAP channels, which use the Enhanced Credit Based Flow Control Mode (that is, distinct Enhanced ATT Bearers).

When using an Enhanced ATT Bearer, ATT MTU and L2CAP MTU are independently configurable and may be reconfigured during a connection. An increase to the MTU is allowed but reducing its size is not. Allowing MTU to be increased without needing to reestablish the connection has an advantage. It eliminates the risk of a second application using the stack, being unable to continue, due to the previously negotiated MTU being too small.

Enhanced ATT bearers are identified through Bearer Ids. Enhanced ATT Bearer Ids are assigned internally and have a valid range between 1 and 251. The Unenhanced ATT bearer is always available for a connected peer device and has the *BearerId 0*.

EATT Credits management Credits for the L2CAP channels used by Enhanced ATT bearers may be managed internally if the autoCreditsMgmt parameter is set to TRUE in the Gap_EattConnectionRequest or Gap_EattConnectionAccept function call. Otherwise, the application is responsible for credits management.

If the application chooses to manage the credits of the L2CAP channels used as Enhanced ATT bearers, it should use the following function to send credits for a specified bearer to a peer device:

```
bleResult_t Gap_EattSendCredits
(
    deviceId_t  deviceId,
    bearerId_t  bearerId,
    uint16_t    credits
);
```

If the local credits or peer credits of the L2CAP channel used by an Enhanced ATT bearer reaches 0, agConnEvtEattBearerStatusNotification_c connection event is updated with a status value ofgEnhancedBearerSuspendedNoLocalCredits_c, or gEnhancedBearerNoPeerCredits_c respectively.

Parent topic: Enhanced ATT

EATT Connection establishment In order to take advantage of the Enhanced ATT features, first a number of Enhanced Bearers should be opened for a connected peer device. For this, the

function below may be used to create up to five Enhanced ATT bearers at a time:

```
bleResult_t Gap_EattConnectionRequest
(
    deviceId_t  deviceId,
    uint16_t    mtu,
    uint8_t     cBearers,
    uint16_t    initialCredits,
    bool_t      autoCreditsMgmt
);
```

The mtu parameter specifies the MTU for all the bearers to be established.

The cBearers parameter is used to specify the number of Enhanced ATT bearers to be opened, and should have a value between 1 and 5. The initialCredits parameter specifies the initial number of credits of the L2CAP credit based channels used as Enhanced ATT bearers.

The autoCreditsMgmt parameter is used to tell the Bluetooth LE Host Stack if it should manage L2CAP channel credits automatically. If set to TRUE the Bluetooth LE Host Stack automatically sends credits to a peer device when exhausted in chunks of initialCredits.

For example, to establish two Enhanced ATT bearers with a peer device the application may call the Gap_EattConnectionRequest as shown below:

```
bleResult_t result = Gap_EattConnectionRequest(peerDeviceId,
                                               64U,
                                               2U,
                                               3U,
                                               TRUE);
if (gBleSuccess_c != result)
{
    /* Treat error */
}
```

If an EATT Connection Request is received from a peer device it would be signaled through the gConnEvtEattConnectionRequest_c connection event of type gapEattConnectionRequest_t sent to the connection callback. The application should handle this event by calling Gap_EattConnectionAccept. The example below shows how an application may accept an incoming EATT Connection Request with the same MTU as requested by the peer device.

```
case gConnEvtEattConnectionRequest_c:
{
    gapEattConnectionRequest_t *pEattConnectionReq = &pConnectionEvent->eventData.
↪eattConnectionRequest;

    bleResult_t result = Gap_EattConnectionAccept(peerDeviceId,
                                                  TRUE,
                                                  pEattConnectionReq->mtu,
                                                  3U,
                                                  TRUE);

    if (gBleSuccess_c != result)
    {
        /* Treat error */
    }
}
break;
```

In case the localMtu specified when accepting a connection differs from the MTU requested by the peer device, the minimum of the two would become the MTU of the Enhanced Bearers.

After the Gap_EattConnectionRequest or Gap_EattConnectionAccept is called, for the result the application should wait for the gConnEvtEattConnectionComplete_c connection event of type gapEattConnectionComplete_t shown below:

```
typedef struct {
    l2caLeCbConnectionRequestResult_t           status;
    uint16_t                                    mtu;
    uint8_t                                     cBearers;
    bearerId_t                                  aBearerIds[gGapEattMaxBearers];
} gapEattConnectionComplete_t;
```

If successful, the aBearerIds array contains the bearer ids, for the Enhanced ATT bearers established. These ids may be used with the GATT Enhanced APIs in order to trigger GATT procedures over Enhanced ATT bearers.

Parent topic: Enhanced ATT

EATT Bearer reconfiguration One of the advantages of Enhanced ATT bearers over the Unenhanced ATT bearer is the ability to increase the MTU multiple times. To reconfigure the MTU and/or MPS of existing Enhanced ATT bearers, the Gap_EattReconfigureRequest should be used. If a mps value of 0 is given, the maximum available MPS value for that channel is used.

For example, in order to reconfigure the MTU of two bearers from 64 to 128 the application may call Gap_EattReconfigureRequest as shown below:

```
bleResult_t result = gBleSuccess_c;
bearerId_t aBearerIds[2] = {1U, 2U};
result = Gap_EattReconfigureRequest(peerDeviceId,
                                    128U,
                                    0U,
                                    2U,
                                    aBearerIds);
if (gBleSuccess_c != result)
{
    /* Treat error */
}
```

The application should monitor the gConnEvtEattChannelReconfigureResponse_c connection event of type gapEattReconfigureResponse_t for the result.

The procedure triggered by Gap_EattReconfigureRequest updates only the local MTU. The ATT_MTU for Enhanced ATT bearers is the minimum of the MTU values of the two devices.

Parent topic: Enhanced ATT

EATT Bearer disconnection Individual Enhanced ATT bearers can be disconnected by calling the Gap_EattDisconnect API as shown below:

```
bleResult_t result = gBleSuccess_c;
result = Gap_EattDisconnect(peerDeviceId, bearerId);
if (gBleSuccess_c != result)
{
    /* Treat error */
}
```

The application should look for a connection event of type gEnhancedBearerDisconnected_c in the connection callback.

Parent topic: Enhanced ATT

Parent topic:*Generic Access Profile (GAP) Layer*

Generic Attribute Profile (GATT) Layer The GATT layer contains the APIs for discovering services and characteristics and transferring data between devices and is built on top of the Attribute Protocol (ATT).

The Attribute Protocol (ATT) transfers data between Bluetooth Low Energy devices on a dedicated L2CAP channel (channel ID 0x04).

As soon as a connection is established between devices, the GATT APIs are readily available. No initialization is required because the L2CAP channel is automatically created.

To identify the GATT peer instance, the same *deviceId* value from the GAP layer (obtained in the *gConnEvtConnected_c*connection event) is used.

There are two GATT roles that define the two devices exchanging data over ATT:

- GATT Server – the device that contains a GATT Database, which is a collection of services and characteristics exposing meaningful data. Usually, the Server responds to *requests* and *commands* sent by the Client. However, it can be configured to send data on its own through *notifications*and *indications*.
- GATT Client – the "active" device that usually sends *requests* and *commands* to the Server to *discover* Services and Characteristics on the Server's Database and to exchange data.

There is no fixed rule deciding which device is the Client and which one is the Server. Any device may initiate a request at any moment. Therefore, it temporarily acts as a Client, at which the peer device may respond, provided it has the Server support and a GATT Database.

Often, a GAP Central acts as a GATT Client to discover Services and Characteristics and obtain data from the GAP Peripheral, which usually has a GATT database. Many standard Bluetooth Low Energy profiles assume that the Peripheral has a database and must act as a Server. However, this is by no means a general rule.

Client APIs A Client can configure the ATT MTU, discover Services and Characteristics, and initiate data exchanges.

All the functions have the same first parameter: a *deviceId* which identifies the connected device whose GATT Server is targeted in the GATT procedure. This is necessary because a Client may be connected to multiple Servers at the same time.

First, however, the application must install the necessary callbacks.

Installing client callbacks There are three callbacks that the Client application must install.

Client procedure callback All the procedures initiated by a Client are asynchronous. They rely on exchanging ATT packets over the air.

To be informed of the procedure completion, the application must install a callback with the following signature:

```
typedef void (* gattClientProcedureCallback_t )
(
    deviceId_t              deviceId,
    gattProcedureType_t     procedureType,
    gattProcedureResult_t   procedureResult,
    bleResult_t             error
);
```

For EATT, the following signature should be used:

```
typedef void (*gattClientEnhancedProcedureCallback_t)
(
   deviceId_t deviceId,
   bearerId_t bearerId,
   gattProcedureType_t procedureType,
   gattProcedureResult_t procedureResult,
   bleResult_t error
);
```

To install this callback, the following function must be called:

```
bleResult_t GattClient_RegisterProcedureCallback
(
    gattClientProcedureCallback_t callback
);
```

The EATT procedure callback should be installed using the following API:

```
bleResult_t GattClient_RegisterEnhancedProcedureCallback
(
 gattClientEnhancedProcedureCallback_t callback
);
```

The *procedureType* parameter can be used to identify the procedure that was started and has reached completion. Only one procedure would be active at a given moment. Trying to start another procedure while a procedure is already in progress returns the error *gGattAnotherProcedureInProgress_c*.

The *procedureResult* parameter indicates whether the procedure completes successfully or an error occurs. In the latter case, the *error* parameter contains the error code.

```
void gatt ClientProcedureCallback
(
    deviceId_t              deviceId,
    gattProcedureType_t     procedureType,
    gattProcedureResult_t   procedureResult,
    bleResult_t             error
)
{
    switch (procedureType)
    {
        /* ... */
    }
}
GattClient_RegisterProcedureCallback(gattClientProcedureCallback);
```

Parent topic: Installing client callbacks

Notification and indication callbacks When the Client receives a notification from the Server, it triggers a callback with the following prototype:

```
typedef void (* gattClientNotificationCallback_t )
(
    deviceId_t      deviceId,
    uint16_t        characteristicValueHandle,
    uint8_t *       aValue,
    uint16_t        valueLength
);
```

The *deviceId* identifies the Server connection (for multiple connections at the same time). The *characteristicValueHandle* is the attribute handle of the Characteristic Value declaration in the GATT Database. The Client must have discovered it previously to be able recognize it.

For EATT, the following signature should be used:

```
typedef void (*gattClientEnhancedNotificationCallback_t)
 ( deviceId_t deviceId,
   bearerId_t bearerId,
   uint16_t characteristicValueHandle,
   uint8_t* aValue,
   uint16_t valueLength );
```

The callback must be installed with:

```
bleResult_t GattClient_RegisterNotificationCallback
(
    gattClientNotificationCallback_t callback
);
```

Very similar definitions exist for indications.

The EATT notification callback should be installed using the following API:

```
bleResult_t GattClient_RegisterEnhancedNotificationCallback
(
 gattClientEnhancedNotificationCallback_t callback
)
```

When receiving a notification or indication, the Client uses the *characteristicValueHandle* to identify which Characteristic was notified. The Client must be aware of the possible Characteristic Value handles that can be notified/indicated at any time, because it has previously activated them by writing its CCCD (see Reading and writing characteristic descriptors).

When the Client receives a multiple value notification from the Server, it triggers a callback with the following prototype:

```
typedef void (*gattClientMultipleValueNotificationCallback_t)
(
    deviceId_t      deviceId,
    /*!< Device ID identifying the active connection. */
    uint8_t* aHandleLenValue,
    /*!< The array of handle, value length, value tuples. */
    uint16_t totalLength
    /*!< Value array size. */
);
```

The callback must be installed with:

```
bleResult_t GattClient_RegisterMultipleValueNotificationCallback
(
    gattClientMultipleValueNotificationCallback_t callback
);
```

When using EATT, the following callback prototype and registration APIs should be used:

```
typedef void (*gattClientEnhancedMultipleValueNotificationCallback_t)
( deviceId_t deviceId,
    /*!< Device ID identifying the active connection. */
  bearerId_t bearerId,
   /*!< Bearer ID identifing the Enhanced ATT bearer used. */
 uint8_t* aHandleLenValue,
   /*!< The array of handle, value length, value tuples. */
uint16_t totalLength      /*!< Value array size. */
 );
```

Parent topic: Installing client callbacks

Parent topic: Client APIs

MTU exchange A radio packet sent over the Bluetooth Low Energy contains a maximum of 27 bytes of data for the L2CAP layer. The L2CAP header is 4 bytes long, including the Channel ID. Therefore, all layers above L2CAP, including ATT and GATT, can only send 23 bytes of data in a radio packet (as per *Bluetooth 4.1 Specification for Bluetooth Low Energy*). This specification also sets the default length of an ATT packet (also called *ATT_MTU*) to 23. The ATT packet length is set to this value to maintain a logical mapping between radio packets and ATT packets.

Note: This number is fixed and cannot be increased in Bluetooth Low Energy 4.1.

Therefore, any ATT request fits in a single radio packet. If the layer above ATT wishes to send more than 23 bytes of data, the data must be fragmented into smaller packets and multiple ATT requests issued.

Despite this setting, the ATT protocol allows devices to increase the ATT_MTU, only if both can support it. Increasing the ATT_MTU has only one effect: the application does not have to fragment long data. However, it can send more than 23 bytes in a single transaction. The fragmentation is moved on to the L2CAP layer. Over the air though, there would still be more than one radio packet sent.

If the GATT Client supports a larger than default MTU, it must start an MTU exchange as soon as it connects to any server. During the MTU exchange, both devices would send their maximum MTU to the other, and the minimum of the two is chosen as the new MTU.

Consider an example where the Client supports a maximum ATT_MTU of 250, and the server supports a maximum value of 120 for the same attribute. For this case, after MTU exchange, both devices must set the new ATT_MTU value equal to 120.

To initiate the MTU exchange, call the following function from *gatt_client_interface.h*:

```
bleResult_t result = GattClient_ExchangeMtu(deviceId, mtu);
if (gBleSuccess_c != result)
{
    /* Treat error */
}
```

When having the role of a GATT Client, the value of the maximum supported *ATT_MTU* of the local device is given as a parameter to the GattClient_ExchangeMtu API. On the GATT Server side, the application configures this value via the gcGattServerMtu_c variable that exists in the file ble_globals.c. The minimum of these two values is chosen as the new MTU for the connection.

When the exchange is complete, the *gGattProcExchangeMtu_c* procedure type triggers the Client callback.

```
void gattClientProcedureCallback
(
    deviceId_t deviceId,
    gattProcedureType_t procedureType,
    gattProcedureResult_t procedureResult,
    bleResult_t error
)
{
    switch (procedureType)
    {
        /* ... */
        case gGattProcExchangeMtu_c*:
            if (gGattProcSuccess_c == procedureResult)
            {
                /* To obtain the new MTU */
                uint16_t newMtu;
                bleResult_t result = Gatt_GetMtu(deviceId, &newMtu);
                if (gBleSuccess_c == result)
                {
                    /* Use the value of the new MTU */
```

(continues on next page)

(continued from previous page)

```
                (void) newMtu;
            }
        }
        else
        {
            /* Handle error */
        }
        break;
    /* ... */
  }
}
```

Note: The Exchange MTU procedure is only available for the unenhanced/legacy bearer. For procedures sent on enhanced bearers, the upper layer must use provided **L2CAP APIs** to create dedicated L2CAP channels. Each channel has its own MTU value specified upon creation, which can also be reconfigured later.

Parent topic: Client APIs

Service and characteristic discovery There are multiple APIs that can be used for Discovery. The application may use any of them, according to its necessities.

All of the following APIs have an enhanced counterpart of the form *GattClient_Enhanced[procedure]*. A *bearerId*parameter was added to specify on which bearer the transaction should take place. A value of *0* for the bearer Id identifies the Unenhanced ATT bearer. Values higher than *0* are used to identify the Enhanced ATT bearer used for the ATT procedure.

Discover all primary services The following API can be used to discover all the Primary Services in a Server's database:

```
bleResult_t GattClient_DiscoverAllPrimaryServices
(
    deviceId_t          deviceId,
    gattService_t *     aOutPrimaryServices,
    uint8_t             maxServiceCount,
    uint8_t *           pOutDiscoveredCount
);
```

The *aOutPrimaryServices* parameter must point to an allocated array of services. The size of the array must be equal to the value of the *maxServiceCount* parameter, which is passed to make sure the GATT module does not attempt to write past the end of the array if more Services are discovered than expected.

The *pOutDiscoveredCount* parameter must point to a static variable because the GATT module uses it to write the number of Services discovered at the end of the procedure. This number is less than or equal to the *maxServiceCount*.

If there is equality, it is possible that the Server contains more than *maxServiceCount* Services, but they could not be discovered as a result of the array size limitation. It is the application developer's responsibility to allocate a large enough number according to the expected contents of the Server's database.

In the following example, the application expects to find no more than 10 Services on the Server.

```
#define mcMaxPrimaryServices_c 10
static gattService_t primaryServices[mcMaxPrimaryServices_c];
uint8_t mcPrimaryServices;
bleResult_t result = GattClient_DiscoverAllPrimaryServices
```

(continues on next page)

(continued from previous page)

```
(
    deviceId,
    primaryServices,
    mcMaxPrimaryServices_c,
    &mcPrimaryServices
);
if (gBleSuccess_c != result)
{
    /* Treat error */
}
```

The operation triggers the Client Procedure Callback when complete. The application may read the number of discovered services and each service's handle range and UUID.

```
void gattClientProcedureCallback
(
    deviceId_t              deviceId,
    gattProcedureType_t     procedureType,
    gattProcedureResult_t   procedureResult,
    bleResult_t             error
)
{
    switch (procedureType)
    {
        /* ... */
        case gGattProcDiscoverAllPrimaryServices_c:
            if (gGattProcSuccess_c == procedureResult)
            {
                /* Read number of discovered services */
                PRINT( mcPrimaryServices );
                /* Read each service's handle range and UUID */
                for (int j = 0; j < mcPrimaryServices; j++)
                {
                    PRINT( primaryServices[j]. startHandle );
                    PRINT( primaryServices[j]. endHandle );
                    PRINT( primaryServices[j]. uuidType );
                    PRINT( primaryServices[j]. uuid );
                }
            }
            else
            {
                /* Handle error */
                PRINT( error );
            }
            break;
        /* ... */
    }
}
```

Parent topic: Service and characteristic discovery

Discover primary services by UUID To discover only Primary Services of a known type (Service UUID), the following API can be used:

```
bleResult_t GattClient_DiscoverPrimaryServicesByUuid
(
    deviceId_t          deviceId,
    bleUuidType_t       uuidType,
    const bleUuid_t *   pUuid,
    gattService_t *     aOutPrimaryServices,
```

(continues on next page)

(continued from previous page)

```
    uint8_t             maxServiceCount,
    uint8_t *           pOutDiscoveredCount
);
```

The procedure is very similar to the one described in Discover all primary services. The only difference is this time we are filtering the search according to a Service UUID described by two extra parameters: *pUuid* and *uuidType*.

This procedure is useful when the Client is only interested in a specific type of Services. Usually, it is performed on Servers that are known to contain a certain Service, which is specific to a certain profile. Therefore, most of the times the search is expected to find a single Service of the given type. As a result, only one structure is usually allocated.

For example, when two devices implement the Heart Rate (HR) Profile, an HR Collector connects to an HR Sensor and may only be interested in discovering the Heart Rate Service (HRS) to work with its Characteristics. The following code example shows how to achieve this. Standard values for Service and Characteristic UUIDs, as defined by the Bluetooth SIG, are located in the *ble_sig_defines.h* file.

```
static gattService_t heartRateService;
static uint8_t mcHrs;
bleResult_t result = GattClient_DiscoverPrimaryServicesByUuid
(
    deviceId,
    gBleUuidType16_c,             /* Service UUID type */
    gBleSig_HeartRateService_d,   /* Service UUID */
    &heartRateService,            /* Only one HRS is expected to be found */
    1,
    &mcHrs
   /* Will be equal to 1 at the end of the procedure
    if the HRS is found, 0 otherwise */

);
if (gBleSuccess_c != result)
{
    /* Treat error */
}
```

In the Client Procedure Callback, the application should check if any Service with the given UUID was found and read its handle range (also perhaps proceed with Characteristic Discovery within that service range).

```
void gattClientProcedureCallback
(
    deviceId_t deviceId,
    gattProcedureType_t procedureType,
    gattProcedureResult_t procedureResult,
    bleResult_t error
)
{
    switch (procedureType)
    {
        /* ... */
        case gGattProcDiscoverPrimaryServicesByUuid_c:
            if (gGattProcSuccess_c == procedureResult)
            {
                if (1 == mcHrs)
                {
                    /* HRS found, read the handle range */
                    PRINT( heartRateService. startHandle );
                    PRINT( heartRateService. endHandle );
```

(continues on next page)

(continued from previous page)

```
            }
            else
            {
                /* HRS not found! */
            }
        }
        else
        {
            /* Handle error */
            PRINT( error );
        }
        break;
    /* ... */
  }
}
```

Parent topic: Service and characteristic discovery

Discover included services Discover all primary services shows how to discover Primary Services. However, a Server may also contain Secondary Services, which are not meant to be used standalone and are usually included in the Primary Services. The inclusion means that all the Secondary Service's Characteristics may be used by the profile that requires the Primary Service.

Therefore, after a Primary Service has been discovered, the following procedure may be used to discover services (usually Secondary Services) included in it:

```
bleResult_t GattClient_FindIncludedServices
(
  deviceId_t          deviceId,
  gattService_t *     pIoService,
  uint8_t             maxServiceCount
);
```

The service structure that *pIoService* points to must have the *aIncludedServices* field linked to an allocated array of services, of size *maxServiceCount*, chosen according to the expected number of included services to be found. This is the application's choice, usually following profile specifications.

Also, the service's range must be set (the *startHandle* and *endHandle* fields), which may have already been done by the previous Service Discovery procedure (as described in Discover all primary services and Discover primary services by UUID).

The number of discovered included services is written by the GATT module in the *cNumIncludedServices* field of the structure from *pIoService*. Obviously, a maximum of *maxServiceCount* included services is discovered.

The following example assumes the Heart Rate Service was discovered using the code provided in Discover primary services by UUID.

```
/* Finding services included in the Heart Rate Primary Service */
gattService_t * pPrimaryService = &heartRateService;
#define mxMaxIncludedServices_c 3
static gattService_t includedServices[mxMaxIncludedServices_c];
/* Linking the array */
pPrimaryService-> aIncludedServices = includedServices;
bleResult_t result = GattClient_FindIncludedServices
(
  deviceId,
  pPrimaryService,
  mxMaxIncludedServices_c
```

(continues on next page)

(continued from previous page)

```
);
if (gBleSuccess_c != result)
{
    /* Treat error */
}
```

When the Client Procedure Callback is triggered, if any included services are found, the application can read their handle range and their UUIDs.

```
void gattClientProcedureCallback
(
    deviceId_t deviceId,
    gattProcedureType_t procedureType,
    gattProcedureResult_t procedureResult,
    bleResult_t error
)
{
    switch (procedureType)
    {
        /* ... */
        case gGattProcFindIncludedServices_c:
            if (gGattProcSuccess_c == procedureResult)
            {
                /* Read included services data */
                PRINT( pPrimaryService-> cNumIncludedServices );
                for (int j = 0; j < pPrimaryService-> cNumIncludedServices ; j++)
                {
                    PRINT( pPrimaryService-> aIncludedServices [j]. startHandle );
                    PRINT( pPrimaryService-> aIncludedServices [j]. endHandle );
                    PRINT( pPrimaryService-> aIncludedServices [j]. uuidType );
                    PRINT( pPrimaryService-> aIncludedServices [j]. uuid );
                }
            }
            else
            {
                /* Handle error */
                PRINT( error );
            }
            break;
        /* ... */
    }
}
```

Parent topic: Service and characteristic discovery

Discover all characteristics of a service The main API for Characteristic Discovery has the following prototype:

```
bleResult_t GattClient_DiscoverAllCharacteristicsOfService
(
    deviceId_t          deviceId,
    gattService_t *     pIoService,
    uint8_t             maxCharacteristicCount
);
```

All required information is contained in the service structure pointed to by *pIoService*, most importantly being the service range (*startHandle* and *endHandle*) which is usually already filled out by a Service Discovery procedure. If not, they need to be written manually.

Also, the service structure's *aCharacteristics* field must be linked to an allocated characteristic array.

The following example discovers all Characteristics contained in the Heart Rate Service discovered in Section Discover primary services by UUID.

```
gattService_t* pService = &heartRateService
#define mcMaxCharacteristics_c 10
static gattCharacteristic_t hrsCharacteristics[mcMaxCharacteristics_c];
pService->aCharacteristics = hrsCharacteristics;
bleResult_t result = GattClient_DiscoverAllCharacteristicsOfService
(
    deviceId,
    pService,
    mcMaxCharacteristics_c
);
```

The Client Procedure Callback is triggered when the procedure completes.

```
void gattClientProcedureCallback
(
    deviceId_t                  deviceId,
    gattProcedureType_t         procedureType,
    gattProcedureResult_t       procedureResult,
    bleResult_t                 error
)
{
    switch (procedureType)
    {
      /* ... */
      case gGattProcDiscoverAllCharacteristics_c:
          if (gGattProcSuccess_c == procedureResult)
          {
            /* Read number of discovered Characteristics */
              PRINT(pService-> cNumCharacteristics );
            /* Read discovered Characteristics data */
              for ( uint8_t j = 0; j < pService-> cNumCharacteristics ; j++)
                {
            /* Characteristic UUID is found inside the value field
               to avoid duplication */
                  PRINT(pService-> aCharacteristics [j]. value . uuidType );
                  PRINT(pService-> aCharacteristics [j]. value . uuid );
            /* Characteristic Properties indicating the supported operations:
                   * - Read
                   * - Write
                   * - Write Without Response
                   * - Notify
                   * - Indicate
            */
                  PRINT(pService-> aCharacteristics [j]. properties );
           /* Characteristic Value Handle is used to identify the
              Characteristic in future operations */
                  PRINT(pService-> aCharacteristics [j]. value . handle );
                }
            }
            else
            {
               /* Handle error */
               PRINT( error );
            }
            break;
        /* ... */
    }
}
```

Parent topic: Service and characteristic discovery

Discover characteristics by UUID This procedure is useful when the Client intends to discover a specific Characteristic in a specific Service. The API allows for multiple Characteristics of the same type to be discovered, but most often it is used when a single Characteristic of the given type is expected to be found.

Continuing the example from Discover primary services by UUID, assume the Client wants to discover the Heart Rate Control Point Characteristic inside the Heart Rate Service, as shown in the following code.

```
gattService_t * pService = &heartRateService;
static gattCharacteristic_t hrcpCharacteristic;
static uint8_t mcHrcpChar;
bleResult_t result = GattClient_DiscoverCharacteristicOfServiceByUuid
(
    deviceId,
    gBleUuidType16_c,
    gBleSig_HrControlPoint_d,
    pService,
    &hrcpCharacteristic,
    1,
    &mcHrcpChar
);
```

This API can be used as in the previous examples, following a Service Discovery procedure. However, the user may want to perform a Characteristic search with UUID over the entire database, skipping the Service Discovery entirely. To do so, a dummy service structure must be defined and its range must be set to maximum, as shown in the following example:

```
gatt Service_t dummyService;
dummyService. startHandle = 0x0001;
dummyService. endHandle = 0xFFFF;
static gattCharacteristic_t hrcpCharacteristic;
static uint8_t mcHrcpChar;
bleResult_t result = GattClient_DiscoverCharacteristicOfServiceByUuid
(
    deviceId,
    gBleUuidType16_c,
    gBleSig_HrControlPoint_d,
    &dummyService,
    &hrcpCharacteristic,
    1,
    &mcHrcpChar
);
```

.

```
void gattClientProcedureCallback
(
    deviceId_t              deviceId,
    gattProcedureType_t     procedureType,
    gattProcedureResult_t   procedureResult,
    bleResult_t             error
)
{
    switch (procedureType)
    {
        /* ... */
        case gGattProcDiscoverCharacteristicByUuid_c:
            if (gGattProcSuccess_c == procedureResult)
            {
                if (1 == mcHrcpChar)
                {
```

(continues on next page)

(continued from previous page)

```
                /* HRCP found, read discovered data */
                PRINT(hrcpCharacteristic. properties );
                PRINT(hrcpCharacteristic. value . handle );
            }
            else
            {
                /* HRCP not found! */
            }
        }
        else
        {
            /* Handle error */
            PRINT(error);
        }
        break;
    /* ... */
  }
}
```

Parent topic: Service and characteristic discovery

Discover characteristic descriptors To discover all descriptors of a Characteristic, the following API is provided:

```
bleResult_t GattClient_DiscoverAllCharacteristicDescriptors
(
  deviceId_t                deviceId,
  gattCharacteristic_t *    pIoCharacteristic,
  uint16_t                  endingHandle,
  uint8_t                   maxDescriptorCount
);
```

The *pIoCharacteristic* pointer must point to a Characteristic structure with the *value.handle* field set (either by a discovery operation or by the application) and the *aDescriptors* field pointed to an allocated array of Descriptor structures.

The *endingHandle* should be set to the handle of the next Characteristic or Service declaration in the database to indicate when the search for descriptors must stop. The GATT Client module uses ATT Find Information Requests to discover the descriptors, and it does so until it discovers a Characteristic or Service declaration or until *endingHandle* is reached. Thus, by providing a correct ending handle, the search for descriptors is optimized and the number of packets sent over the air is reduced.

If, however, the application does not know where the next declaration lies and cannot provide this optimization hint, the *endingHandle* should be set to *0xFFFF*.

Continuing the example from Discover characteristics by UUID, the following code assumes that the Heart Rate Control Point Characteristic has no more than 5 descriptors and performs Descriptor Discovery.

```
#define mcMaxDescriptors_c 5
static gattAttribute_t aDescriptors[mcMaxDescriptors_c];
hrcpCharacteristic. aDescriptors = aDescriptors;
bleResult_t result = GattClient_DiscoverAllCharacteristicDescriptors
(
  deviceId,
  &hrcpCharacteristic,
  0xFFFF, /* We do not know where the next Characterstic Service begins */
  mcMaxDescriptors_c
);
```

(continues on next page)

(continued from previous page)

```
if (gBleSuccess_c != result)
{
    /* Handle error */
}
```

The Client Procedure Callback is triggered at the end of the procedure.

```
void gattClientProcedureCallback
(
    deviceId_t              deviceId,
    gattProcedureType_t     procedureType,
    gattProcedureResult_t   procedureResult,
    bleResult_t             error
)
{
    switch (procedureType)
    {
        /* ... */
        case gGattProcDiscoverAllCharacteristicDescriptors_c:
            if (gGattProcSuccess_c == procedureResult)
            {
                /* Read number of discovered descriptors */
                PRINT(hrcpCharacteristic. cNumDescriptors );
                /* Read descriptor data */
                for ( uint8_t j = 0; j < hrcpCharacteristic. cNumDescriptors ; j++)
                {
                    PRINT(hrcpCharacteristic. aDescriptors [j]. handle );
                    PRINT(hrcpCharacteristic. aDescriptors [j]. uuidType );
                    PRINT(hrcpCharacteristic. aDescriptors [j]. uuid );
                }
            }
            else
            {
                /* Handle error */
                PRINT(error);
            }
            break;
        /* ... */
    }
}
```

Parent topic: Service and characteristic discovery

Parent topic: Client APIs

Reading and writing characteristics All the APIs described in the following sections have an enhanced counterpart of the form *GattClient_Enhanced[procedure]*. A *bearer id* parameter was added to specify on which bearer the transaction should take place. A value of *0* for the bearer id identifies the Unenhanced ATT bearer. Values higher than *0* are used to identify the Enhanced ATT bearer used for the ATT procedure.

Characteristic value read procedure The main API for reading a Characteristic Value is shown here:

```
bleResult_t GattClient_ReadCharacteristicValue
(
    deviceId_t                deviceId,
    gattCharacteristic_t *    pIoCharacteristic,
```

(continues on next page)

(continued from previous page)

```
    uint16_t                maxReadBytes
);
```

This procedure assumes that the application knows the Characteristic Value Handle, usually from a previous Characteristic Discovery procedure. Therefore, the *value.handle* field of the structure pointed by *pIoCharacteristic* must be completed.

Also, the application must allocate a large enough array of bytes where the received value (from the ATT packet exchange) is written. The *maxReadBytes* parameter is set to the size of this allocated array.

The GATT Client module takes care of long characteristics, whose values have a greater length than can fit in a single ATT packet, by issuing repeated ATT Read Blob Requests when needed.

The following examples assume that the application knows the Characteristic Value Handle and that the value length is variable, but limited to 50 bytes.

```
gattCharacteristic_t myCharacteristic;
myCharacteristic.value.handle = 0x10AB;
#define mcMaxValueLength_c 50
static uint8_t aValue[mcMaxValueLength_c];
myCharacteristic.value.paValue = aValue;
bleResult_t result = GattClient_ReadCharacteristicValue
(
    deviceId,
    &myCharacteristic,
    mcMaxValueLength_c
);
if (gBleSuccess_c != result)
{
    /* Handle error */
}
```

Regardless of the value length, the Client Procedure Callback is triggered when the reading is complete. The received value length is also filled in the *value* structure.

```
void gattClientProcedureCallback
(
    deviceId_t              deviceId,
    gattProcedureType_t     procedureType,
    gattProcedureResult_t   procedureResult,
    bleResult_t             error
)
{
    switch (procedureType)
    {
        /* ... */
        case gGattProcReadCharacteristicValue_c:
            if (*gGattProcSuccess_c == procedureResult)
            {
                /* Read value length */
                PRINT(myCharacteristic.value.valueLength );
                /* Read data */
                for ( uint16_t j = 0; j < myCharacteristic.value.valueLength ; j++)
                {
                    PRINT(myCharacteristic.value.paValue [j]);
                }
            }
            else
            {
                /* Handle error */
                PRINT(error);
```

(continues on next page)

(continued from previous page)

```
            }
            break;
        /* ... */
    }
}
```

Parent topic: Reading and writing characteristics

Characteristic read by UUID procedure This API for this procedure is shown here:

```
bleResult_t GattClient_ReadUsingCharacteristicUuid
(
    deviceId_t              deviceId,
    bleUuidType_t           uuidType,
    const bleUuid_t*        pUuid,
    const gattHandleRange_t* pHandleRange,
    uint8_t*                aOutBuffer,
    uint16_t                maxReadBytes,
    uint16_t*               pOutActualReadBytes
);
```

This provides support for an important optimization, which involves reading a Characteristic Value without performing any Service or Characteristic Discovery.

For example, the following is the process to write an application that connects to any Server and wants to read the device name.

The device name is contained in the Device Name Characteristic from the GAP Service. Therefore, the necessary steps involve discovering all primary services, identifying the GAP Service by its UUID, discovering all Characteristics of the GAP Service and identifying the Device Name Characteristic (alternatively, discovering Characteristic by UUID inside GAP Service), and, finally, reading the device name by using the Characteristic Read Procedure.

Instead, the Characteristic Read by UUID Procedure allows reading a Characteristic with a specified UUID, assuming one exists on the Server, without knowing the Characteristic Value Handle.

The described example is implemented as follows:

```
#define mcMaxValueLength_c
/* First byte is for handle-value pair length. Next 2 bytes are the handle */
static uint8_t aValue[1 + 2 + mcMaxValueLength_c];
static uint16_t deviceNameLength;
bleUuid_t uuid = {
        .uuid16 = gBleSig_GapDeviceName_d
};
bleResult_t result = GattClient_ReadUsingCharacteristicUuid
(
    deviceId,
    gBleUuidType16_c,
    &uuid,
    &pHandleRange,
    aValue,
    1 + 2 + mcMaxValueLength_c,
    deviceNameLength
);
if (gBleSuccess_c != result)
{
    /* Handle error */
}
```

The Client Procedure Callback is triggered when the reading is complete. Because only one air

packet is exchanged during this procedure, it can only be used as a quick reading of Characteristic Values with length no greater than *ATT_MTU – 1*.

```
void gattClientProcedureCallback
(
    deviceId_t                  deviceId,
    gattProcedureType_t         procedureType,
    gattProcedureResult_t       procedureResult,
    bleResult_t                 error
)
{
    switch (procedureType)
    {
        /* ... */
         case gGattProcReadUsingCharacteristicUuid_c:
              if (gGattProcSuccess_c == procedureResult)
            {
               /* Read handle-value pair length */
                PRINT(aValue[0]);
                deviceNameLength -= 1;
              /* Read characteristic value handle */
                PRINT(aValue[1] | (aValue[2] << 8));
                deviceNameLength -= 2;
                /* Read value length */
                PRINT(deviceNameLength);
                /* Read data */
                for ( uint8_t j = 0; j < deviceNameLength; j++)
                {
                    PRINT(aValue[3 + j]);
                }
            }
             else
            {
                /* Handle error */
                PRINT(error);
            }
            break;
        /* ... */
    }
}
```

Parent topic: Reading and writing characteristics

Characteristic read multiple procedure

The API for this procedure is shown here:

```
bleResult_t GattClient_ReadMultipleCharacteristicValues
(
    deviceId_t                  deviceId,
    uint8_t                     cNumCharacteristics,
    gattCharacteristic_t *      aIoCharacteristics
);
```

This procedure also allows an optimization for a specific situation, which occurs when multiple Characteristics, whose values are of known, fixed-length, can be all read in one single ATT transaction (usually one single over-the-air packet).

The application must know the value handle and value length of each Characteristic. It must also write the *value.handle*and *value.maxValueLength* with the aforementioned values, respectively, and then link the *value.paValue* field with an allocated array of size *maxValueLength*.

The following example involves reading three characteristics in a single packet.

```
#define mcNumCharacteristics_c 3
#define mcChar1Length_c 4
#define mcChar2Length_c 5
#define mcChar3Length_c 6
static uint8_t aValue1[mcChar1Length_c];
static uint8_t aValue2[mcChar2Length_c];
static uint8_t aValue3[mcChar3Length_c];
static gattCharacteristic_t myChars[mcNumCharacteristics_c];
myChars[0]. value . handle = 0x0015;
myChars[1]. value . handle = 0x0025;
myChars[2]. value . handle = 0x0035;
myChars[0]. value . maxValueLength = mcChar1Length_c;
myChars[1]. value . maxValueLength = mcChar2Length_c;
myChars[2]. value . maxValueLength = mcChar3Length_c;
myChars[0]. value . paValue = aValue1;
myChars[1]. value . paValue = aValue2;
myChars[2]. value . paValue = aValue3;
bleResult_t result = GattClient_ReadMultipleCharacteristicValues
(
    deviceId,
    mcNumCharacteristics_c,
    myChars
);
if (gBleSuccess_c != result)
{
    /* Handle error */
}
```

When the Client Procedure Callback is triggered, if no error occurs, each Characteristic's value length should be equal to the requested lengths.

```
void gattClientProcedureCallback
(
    deviceId_t              deviceId,
    gattProcedureType_t p  rocedureType,
    gattProcedureResult_t  procedureResult,
    bleResult_t             error
)
{
    switch (procedureType)
    {
        /* ... */
      case gGattProcReadMultipleCharacteristicValues_c:
          if (gGattProcSuccess_c == procedureResult)
          {
              for ( uint8_t i = 0; i < mcNumCharacteristics_c; i++)
              {
                  /* Read value length */
                  PRINT(myChars[i]. value . valueLength );
                  /* Read data */
                  for ( uint8_t j = 0; j < myChars[i]. value . valueLength ; j++)
                  {
                      PRINT(myChars[i]. value . paValue [j]);
                  }
              }
          }
          else
          {
              /* Handle error */
              PRINT(error);
          }
          break;
```

(continues on next page)

(continued from previous page)

```
        /* ... */
    }
}
```

If the server does not know the length of the characteristic values, then the Read Multiple Variable Characteristic Values procedure can be used. This sub-procedure is used to read multiple characteristic values of variable length from a server when the client knows the characteristic value handles. The response returns the characteristic values and their corresponding lengths in the Length Value Tuple List parameter.

```
bleResult_t GattClient_ReadMultipleVariableCharacteristicValues
(
  deviceId_t             deviceId,
  uint8_t                cNumCharacteristics,
  gattCharacteristic_t*  pIoCharacteristics
);
```

The following example involves reading three characteristics of variable length in a single packet.

```
#define mcNumCharacteristics_c 3
#define mcCharLengthMax_c 10
static uint8_t aValue1[mcCharLengthMax _c];
static uint8_t aValue2[mcCharLengthMax _c];
static uint8_t aValue3[mcCharLengthMax _c];
static gattCharacteristic_t myChars[mcNumCharacteristics_c];
myChars[0].value .handle = 0x0015;
myChars[1].value .handle = 0x0025;
myChars[2].value .handle = 0x0035;
myChars[0].value .paValue = aValue1;
myChars[1].value .paValue = aValue2;
myChars[2].value .paValue = aValue3;
bleResult_t result = GattClient_ReadMultipleVariableCharacteristicValues
(
    deviceId,
    mcNumCharacteristics_c,
    pIoCharacteristics
);
if (gBleSuccess_c != result)
{
    /* Handle error */
}
```

The result of this procedure is sent to the application via the GATT procedure callback. The response includes the characteristic value together with a handle, length pair corresponding to each characteristic.

```
static void BleApp_GattClientCallback
(
    deviceId_t              serverDeviceId,
    gattProcedureType_t     procedureType,
    gattProcedureResult_t   procedureResult,
    bleResult_t             error
)
{
    switch (procedureResult)
    {
        /* ... */
        case gGattProcReadMultipleVarLengthCharValues_c:
            if (gGattProcSuccess_c == procedureResult)
            {
```

(continues on next page)

(continued from previous page)

```
            for (uint8_t i = 0; i < mcNumCharacteristics_c; i++)
            {
                /* Print characteristic handle and length */
                PRINT(myChars[i].value.handle);
                PRINT(myChars[i].value.valueLength);
                for (uint8_t j = 0; j < myChars[i].value.maxValueLength; j++)
                {
                    /* Print characteristic value */
                    PRINT(myChars[i].value.paValue[j]);
                }
            }
        }
        else
        {
            /* Handle error */
        }
        break;
}
```

Parent topic: Reading and writing characteristics

Characteristic write procedure There is a general API that may be used for writing Characteristic Values:

```
bleResult_t GattClient_WriteCharacteristicValue
(
    deviceId_t                      deviceId,
    const gattCharacteristic_t *    pCharacteristic,
    uint16_t                        valueLength,
    const uint8_t *                 aValue,
    bool_t                          withoutResponse,
    bool_t                          signedWrite,
    bool_t                          doReliableLongCharWrites,
    const uint8_t *                 aCsrk
);
```

It has many parameters to support different combinations of Characteristic Write Procedures.

The structure pointed to by the *pCharacteristic* is only used for the *value.handle*field which indicates the Characteristic Value Handle. The value to be written is contained in the *aValue* array of size *valueLength*.

The *withoutResponse* parameter can be set to *TRUE* if the application wishes to perform a Write Without Response Procedure, which translates into an ATT Write Command. If this value is selected, the *signedWrite* parameter indicates whether data should be signed (Signed Write Procedure over ATT Signed Write Command), in which case the *aCsrk* parameters must not be NULL and contains the CSRK to sign the data with. Otherwise, both *signedWrite* and *aCsrk* are ignored.

Finally, *doReliableLongCharWrites* should be sent to *TRUE* if the application is writing a long Characteristic Value (one that requires multiple air packets due to *ATT_MTU* limitations) and wants the Server to confirm each part of the attribute that is sent over the air.

To simplify the application code, the following macros are defined:

```
#define GattClient_SimpleCharacteristicWrite(deviceId, pChar, valueLength, aValue) \
    GattClient_WriteCharacteristicValue\
        (deviceId, pChar, valueLength, aValue, FALSE, FALSE, FALSE, NULL)
```

This is the simplest usage for writing a Characteristic. It sends an ATT Write Request if the value length does not exceed the maximum space for an over-the-air packet (*ATT_MTU – 3*). Otherwise,

it sends ATT Prepare Write Requests with parts of the attribute, without checking the ATT Prepare Write Response data for consistency, and in the end an ATT Execute Write Request.

```
#define GattClient_CharacteristicWriteWithoutResponse(deviceId, pChar, valueLength, aValue) \
    GattClient_WriteCharacteristicValue\
        (deviceId, pChar, valueLength, aValue, TRUE, FALSE, FALSE, NULL)
```

This usage sends an ATT Write Command. Long Characteristic values are not allowed here and trigger a *gBleInvalidParameter_c* error.

```
#define GattClient_CharacteristicSignedWrite(deviceId, pChar, valueLength, aValue, aCsrk) \
    GattClient_WriteCharacteristicValue\
        (deviceId, pChar, valueLength, aValue, TRUE, TRUE, FALSE, aCsrk)
```

This usage sends an ATT Signed Write Command. The CSRK used to sign data must be provided.

This is a short example to write a 3-byte long Characteristic Value.

```
gattCharacteristic_t myChar;
myChar. value . handle = 0x00A0; /* Or maybe it was previously discovered? */
#define mcValueLength_c 3
uint8_t aValue[mcValueLength_c] = { 0x01, 0x02, 0x03 };
bleResult_t result = GattClient_SimpleCharacteristicWrite
(
    deviceId,
    &myChar,
    mcValueLength_c,
    aValue
);
if (gBleSuccess_c != result)
{
    /* Handle error */
}
```

The Client Procedure Callback is triggered when writing is complete.

```
void gattClientProcedureCallback
(
    deviceId_t                  deviceId,
    gattProcedureType_t         procedureType,
    gattProcedureResult_t       procedureResult,
    bleResult_t                 error
)
{
    switch (procedureType)
    {
        /* ... */
        case gGattProcWriteCharacteristicValue_c:
            if (gGattProcSuccess_c == procedureResult)
            {
                /* Continue */
            }
            else
            {
                /* Handle error */
                PRINT(error);
            }
            break;
        /* ... */
    }
}
```

Parent topic: Reading and writing characteristics

Parent topic: Client APIs

Reading and writing characteristic descriptors Two APIs are provided for these procedures which are very similar to Characteristic Read and Write.

The only difference is that the handle of the attribute to be read/written is provided through a pointer to an *gattAttribute_t* structure (same type as the *gattCharacteristic_t.value* field).

All of the following APIs have an enhanced counterpart of the form *GattClient_Enhanced[procedure]*. A *bearerId*parameter was added to specify on which bearer the transaction should take place. A value of *0* for the bearer Id identifies the Unenhanced ATT bearer. Values higher than *0* are used to identify the Enhanced ATT bearer used for the ATT procedure.

```
bleResult_t GattClient_ReadCharacteristicDescriptor
(
    deviceId_t              deviceId,
    gattAttribute_t *       pIoDescriptor,
    uint16_t                maxReadBytes
);
```

The *pIoDescriptor->handle* is required (it may have been discovered previously by *GattClient_DiscoverAllCharacteristicDescriptors*). The GATT module fills the value that was read in the fields *pIoDescriptor->aValue* (must be linked to an allocated array) and *pIoDescriptor->valueLength* (size of the array).

Writing a descriptor is also performed similarly with this function:

```
bleResult_t GattClient_WriteCharacteristicDescriptor
(
    deviceId_t              deviceId,
    gattAttribute_t *       pDescriptor,
    uint16_t                valueLength,
    uint8_t *               aValue
);
```

Only the *pDescriptor->handle* must be filled before calling the function.

One of the most frequently written descriptors is the Client Characteristic Configuration Descriptor (CCCD). It has a well-defined UUID (*gBleSig_CCCD_d*) and a 2-byte long value that can be written to enable/disable notifications and/or indications.

In the following example, a Characteristic's descriptors are discovered and its CCCD written to activate notifications.

```
static gattCharacteristic_t myChar;
myChar. value . handle = 0x00A0; /* Or maybe it was previously discovered? */
#define mcMaxDescriptors_c 5
static gattAttribute_t aDescriptors[mcMaxDescriptors_c];
myChar. aDescriptors = aDescriptors;
/* ... */
{
    bleResult_t result = GattClient_DiscoverAllCharacteristicDescriptors
    (
        deviceId,
        &myChar,
        0xFFFF,
        mcMaxDescriptors_c
    );
    if (gBleSuccess_c != result)
    {
        /* Handle error */
```

(continues on next page)

(continued from previous page)

```
    }
}
/* ... */
void gattClientProcedureCallback
(
    deviceId_t                  deviceId,
    gattProcedureType_t         procedureType,
    gattProcedureResult_t       procedureResult,
    bleResult_t                 error
)
{
    switch (procedureType)
    {
      /* ... */
      case gGattProcDiscoverAllCharacteristicDescriptors_c:
         if (gGattProcSuccess_c == procedureResult)
          {
           /* Find CCCD */
            for ( uint8_t j = 0; j < myChar. cNumDescriptors ; j++)
               {
                if (aDescriptors[j].uuidType && gBleSig_CCCD_d ==myChar.aDescriptors[j].uuid.uuid16) )
                 {
                    uint8_t cccdValue[2];
                    packTwoByteValue(gCccdNotification_c, cccdValue);
                    bleResult_t result = GattClient_WriteCharacteristicDescriptor
                     (
                       deviceId,
                       &myChar. aDescriptors [j],
                       2,
                       cccdValue
                     );
                    if (gBleSuccess_c != result)
                       {
                        /* Handle error */
                       }
                       break;
                     }
               }
            }
            else
            {
                /* Handle error */
                PRINT(error);
            }
            break;
        case gGattProcWriteCharacteristicDescriptor_c:
            if (gGattProcSuccess_c == procedureResult)
            {
                /* Notification successfully activated */
            }
            else
            {
                /* Handle error */
                PRINT(error);
            }
        /* ... */
    }
}
```

Parent topic: Client APIs

Resetting procedures To cancel an ongoing Client Procedure, the following API can be called:

```
bleResult_t GattClient_ResetProcedure (void);
```

It resets the internal state of the GATT Client and new procedure may be started at any time.

Parent topic: Client APIs

Parent topic:*Generic Attribute Profile (GATT) Layer*

Server APIs Once the GATT Database has been created and the required security settings have been registered with *Gap_RegisterDeviceSecurityRequirements*, all ATT Requests and Commands and attribute access security checks are handled internally by the GATT Server module.

Besides this automatic functionality, the application may use GATT Server APIs to send Notifications and Indication and, optionally, to intercept Clients' attempts to write certain attributes.

Server callback The first GATT Server call is the installation of the Server Callback, which has the following prototype:

```
typedef void (* gattServerCallback_t )
(
    deviceId_t              deviceId,    /*!< Device ID identifying the active connection. */
    gattServerEvent_t *     pServerEvent /*!< Server event. */
);
```

For EATT, the following signature should be used:

```
typedef void (*gattServerEnhancedCallback_t) ( deviceId_t deviceId, bearerId_t bearerId, gattServerEvent_
↪t* pServerEvent );
```

The callback can be installed with:

```
bleResult_t GattServer_RegisterCallback
(
    gattServerCallback_t callback
);
```

The EATT server callback should be installed using the following API:

```
bleResult_t GattServer_RegisterEnhancedCallback
(
     gattServerEnhancedCallback_t callback
);
```

The first member of the *gattServerEvent_t* structure is the *eventType*, an enumeration type with the following possible values:

- *gEvtMtuChanged_c:* Signals that the Client-initiated MTU Exchange Procedure has completed successfully and the *ATT_MTU* has been increased. The event data contains the new value of the *ATT_MTU*. Is it possible that the application flow depends on the value of the *ATT_MTU*, for example, there may be specific optimizations for different *ATT_MTU* ranges. This event is not triggered if the *ATT_MTU* was not changed during the procedure.
- *gEvtHandleValueConfirmation_c:* A Confirmation was received from the Client after an Indication was sent by the Server.
- *gEvtAttributeWritten_c, gEvtAttributeWrittenWithoutResponse_c:* See Attribute write notifications.
- *gEvtCharacteristicCccdWritten_c:* The Client has written a CCCD. The application should save the CCCD value for bonded devices with *Gap_SaveCccd*.

- *gEvtError_c:* An error occurred during a Server-initiated procedure.
- *gEvtLongCharacteristicWritten_c*: A long characteristic was written.
- *gEvtInvalidPduReceived_c*: An invalid PDU was received from Client. Application decides if disconnection is required.
- *gEvtAttributeRead_c*: An attribute registered with GattServer_RegisterHandlesForReadNotifications is being read.

Parent topic: Server APIs

Sending notifications and indications The APIs provided for these Server-initiated operations are very similar.

All of the following APIs have an enhanced counterpart of the form *GattServer_Enhanced[procedure]*. A *bearerId* parameter was added to specify on which bearer the transaction should take place. A value of *0* for the bearerId identifies the Unenhanced ATT bearer. Values higher than*0* are used to identify the Enhanced ATT bearer used for the ATT procedure.

```
bleResult_t GattServer_SendNotification
(
    deviceId_t      deviceId,
    uint16_t        handle
);
bleResult_t GattServer_SendIndication
(
    deviceId_t      deviceId,
    uint16_t        handle
);
```

Only the attribute handle needs to be provided to these functions. The attribute value is automatically retrieved from the GATT Database.

Note: It is the application developer's responsibility to check if the Client designated by the *deviceId* has previously activated Notifications/Indications by writing the corresponding CCCD value. To do that, the following GAP APIs should be used:

```
bleResult_t Gap_CheckNotificationStatus
(
    deviceId_t      deviceId,
    uint16_t        handle,
    bool_t *        pOutIsActive
);
bleResult_t Gap_CheckIndicationStatus
(
    deviceId_t      deviceId,
    uint16_t        handle,
    bool_t *        pOutIsActive
    );
```

Note: It is necessary to use these two functions with the *Gap_SaveCccd* only for bonded devices, because the data is saved in NVM and reloaded at reconnection. For devices that do not bond, the application may also use its own bookkeeping mechanism.

There is an important difference between sending **Notifications and Indications**:

- The latter can only be sent one at a time. In addition, the application must wait for the Client Confirmation (signaled by the *gEvtHandleValueConfirmation_c* Server event, or by a *gEvtError_c* event with *gGattClientConfirmationTimeout_c* error code) before sending a new Indication. Otherwise, a *gEvtError_c* event with *gGattIndicationAlreadyInProgress_c* error code is triggered.

- The Notifications can be sent consecutively.

Parent topic: Server APIs

Attribute write notifications When the GATT Client reads and writes values from/into the Server's GATT Database, it uses ATT Requests.

The GATT Server module implementation manages these requests and, according to the database security settings and the Client's security status (authenticated, authorized, and so on), automatically sends the ATT Responses without notifying the application.

There are however some situations where the application needs to be informed of ATT packet exchanges. For example, a lot of standard profiles define, for certain Services, some, so-called, Control-Point Characteristics. These are Characteristics whose values are only of immediate significance to the application. Writing these Characteristics usually triggers specific actions.

For example, consider a fictitious Smart Lamp. It has Bluetooth Low Energy connectivity in the Peripheral role and it contains a small GATT Database with a Lamp Service (among other Services). The Lamp Service contains two Characteristics: the Lamp State Characteristic (LSC) and the Lamp Action Characteristic (LAC).

LSC is a "normal" Characteristic with Read and Write properties. Its value is either 0, lamp off, or 1, lamp on). Writing the value sets the lamp in the desired state. Reading it provides its current state, which is only useful when passing the information remotely.

The LAC has only one property, which is Write Without Response. The user can use the Write Without Response procedure to write only the value 0x01 (all other values are invalid). Whenever the user writes 0x01 in LAC, the lamp switches its state.

The LAC is a good example of a Control-Point Characteristic for these reasons:

- Writing a certain value (in this case 0x01) triggers an action on the lamp.
- The value the user writes has immediate significance only ("0x01 switches the lamp") and is never used again in the future. For this reason, it does not need to be stored in the database.

Obviously, whenever a Control-Point Characteristic is written, the application must be notified to trigger some application-specific action.

The GATT Server allows the application to register a set of attribute handles as "write-notifiable", in other words, the application wants to receive an event each time any of these attributes is written by the peer Client.

All Control-Point Characteristics in the GATT Database must have their Value handle registered. In fact, the application may register any other handle for write notifications for its own purposes with the following API:

```
bleResult_t GattServer_RegisterHandlesForWriteNotifications
(
    uint8_t         handleCount,
    const uint16_t *    aAttributeHandles
);
```

The *handleCount* is the size of the *aAttributeHandles* array and it cannot exceed *gcGattMaxHandleCountForWriteNotifications_c*.

After an attribute handle has been registered with this function, whenever the Client attempts to write its value, the GATT Server Callback is triggered with one of the following event types:

- *gEvtAttributeWritten_c* is triggered when the attribute is written with a Write procedure (ATT Write Request). In this instance, the application has to decide whether the written value is valid and whether it must be written in the database, and, if so, the application must write the value with the *GattDb_WriteAttribute*, see *GATT database application interface*. At this point, the GATT Server module does not automatically send the ATT Write Response over the air. Instead, it waits for the application to call this function:

```
bleResult_t GattServer_SendAttributeWrittenStatus
(
    deviceId_t      deviceId,
    uint16_t        attributeHandle,
    uint8_t         status
);
```

This API also has an enhanced counterpart, which adds the *bearerId* parameter.

The value of the *status* parameter is interpreted as an ATT Error Code. It must be equal to the *gAttErrCodeNoError_c* (0x00) if the value is valid and it is successfully processed by the application. Otherwise, it must be equal to a profile-specific error code (in interval 0xE0-0xFF) or an application-specific error code (in interval 0x80-0x9F).

- *gEvtAttributeWrittenWithoutResponse_c* is triggered when the attribute is written with a Write Without Response procedure (ATT Write Command). Because this procedure expects no response, the application may process it and, if necessary, write it in the database. Regardless of whether the value is valid or not, no response is needed from the application.
- *gEvtLongCharacteristicWritten_c* is triggered when the Client has completed writing a Long Characteristic value; the event data includes the handle of the Characteristic Value attribute and a pointer to its value in the database.

Attributes can also be registered for read notifications using the followng API:

```
bleResult_t GattServer_RegisterHandlesForReadNotifications
(
 uint8_t handleCount,
 const uint16_t* aAttributeHandles
);
```

To unregister one or more handles from the list for either write or read, the following APIs can be used:

```
bleResult_t GattServer_UnregisterHandlesForWriteNotifications
(
 uint8_t handleCount,
 const uint16_t* aAttributeHandles
);

bleResult_t GattServer_UnregisterHandlesForReadNotifications
(
 uint8_t handleCount,
 const uint16_t* aAttributeHandles
);
```

Parent topic: Server APIs

Parent topic:*Generic Attribute Profile (GATT) Layer*

GATT database application interface For over-the-air packet exchanges between a Client and a Server, the GATT Server module automatically retrieves data from the GATT database and responds to all ATT Requests from the peer Client, provided it passes the security checks. This ensures that the Server application does not have to perform any kind of searches over the database.

However, the application must have access to the database to write meaningful data into its characteristics. For example, a temperature sensor must periodically write the temperature, which is measured by an external thermometer, into the Temperature Characteristic.

For these kinds of situations, a few APIs are provided in the *gatt_db_app_interface.h* file.

Note: All functions provided by this interface are executed synchronously. The result of the operation is saved in the return value and it generates no event.

Writing and reading attributes These are the two functions to perform basic attribute operations from the application:

```
bleResult_t GattDb_WriteAttribute
(
    uint16_t            handle,
    uint16_t            valueLength,
    const uint8_t *     aValue
);
```

The value length must be valid, as defined when the database is created. Otherwise, a *gGattInvalidValueLength_c* error is returned.

Also, if the database is created statically, as explained in *Creating GATT database*, the *handle* may be referenced through the enumeration member with a friendly name defined in the *gatt_db.h*.

```
bleResult_t GattDb_ReadAttribute
(
    uint16_t      handle,
    uint16_t      maxBytes,
    uint8_t *     aOutValue,
    uint16_t *    pOutValueLength
);
```

The *aOutValue* array must be allocated with the size equal to *maxBytes*.

Parent topic:*GATT database application interface*

Finding attribute handles Although the application should be fully aware of the contents of the GATT Database, in certain situations it might be useful to perform some dynamic searches of certain attribute handles.

To find the handle value for a Service for which only the UUID is know the following API can be used:

```
bleResult_t GattDb_FindServiceHandle
(
 uint16_t startHandle,
 bleUuidType_t serviceUuidType,
 const bleUuid_t* pServiceUuid,
 uint16_t* pOutServiceHandle
);
```

To find a specific Characteristic Value Handle in a Service whose declaration handle is known, the following API is provided:

```
bleResult_t GattDb_FindCharValueHandleInService
(
    uint16_t                serviceHandle,
    bleUuidType_t           characteristicUuidType,
    const bleUuid_t *       pCharacteristicUuid,
    uint16_t *              pOutCharValueHandle
);
```

If the return value is *gBleSuccess_c*, the handle is written at *pOutCharValueHandle*. If the *serviceHandle* is invalid or not a valid Service declaration, the *gBleGattDbInvalidHandle_c* is returned. Otherwise, the search is performed starting with the *serviceHandle+1*. If no Characteristic of the given UUID is found, the function returns the *gBleGattDbCharacteristicNotFound_c* value.

To find a Characteristic Descriptor of a given type in a Characteristic, when the Characteristic Value Handle is known, the following API is provided:

```
bleResult_t GattDb_FindDescriptorHandleForCharValueHandle
(
    uint16_t            charValueHandle,
    bleUuidType_t       descriptorUuidType,
    const bleUuid_t *   pDescriptorUuid,
    uint16_t *          pOutDescriptorHandle
);
```

Similarly, the function returns *gBleGattDbInvalidHandle_c* is the handle is invalid. Otherwise, it starts searching from the *charValueHandle+1*. Then, *gBleGattDbDescriptorNotFound_c* is returned if no Descriptor of the specified type is found. Otherwise, its attribute handle is written at the *pOutDescriptorHandle* and the function returns *gBleSuccess_c*.

One of the most commonly used Characteristic Descriptors is the Client Configuration Characteristic Descriptor (CCCD), which has the UUID equal to *gBleSig_CCCD_d*. For this specific type, a special API is used as a shortcut:

```
bleResult_t GattDb_FindCccdHandleForCharValueHandle
(
    uint16_t     charValueHandle,
    uint16_t *   pOutCccdHandle
);
```

Parent topic:*GATT database application interface*

Creating GATT database The GATT Database contains several *GATT Services* where each Service must contain at least one *GATT Characteristic*.

The Attribute Database contains a collection of *attributes*. Each attribute has four fields:

- The *attribute handle* – a 2-byte database index, which starts from 0x0001 and increases with each new attribute, not necessarily consecutive; maximum value is 0xFFFF.
- The *attribute type* or *UUID* – a 2-byte or 16-byte UUID.
- The *attribute permissions* – 1 byte containing access flags; this defines whether the attribute's value can be read or written and the security requirements for each operation type
- The *attribute value* – an array of maximum 512 bytes.

The ATT does not interpret the UUIDs and values contained in the database. It only deals with data transfer based on the attributes' handles.

The GATT gives meaning to the attributes based on their UUIDs and groups them into Characteristics and Services.

There are two possible ways of defining the GATT database:

- At compile-time (statically) or
- At runtime (dynamically)

Creating static GATT database To define a GATT Database at compile-time, several macros are provided by the GATT_DB API. These macros expand in many different ways at compilation, generating the corresponding *Attribute Database* on which the Attribute Protocol (ATT) may operate.

This is the default way of defining the database.

The GATT Database definition is written in two files that are required to be added to the application project together with all macro expansion files:

- ***gatt_db.h*** - contains the actual declaration of Services and Characteristics.
- ***gat_uuid128.h*** – contains the declaration of Custom UUIDs (16-byte wide); these UUIDs are given a user-friendly name that is used in *gatt_db.h* file instead of the entire 16-byte sequence.

Declaring custom 128-bit UUIDs All Custom 128-bit UUIDs are declared in the required file *gatt_uuid128.h*.

Each line in this file contains a single UUID declaration. The declaration uses the following macro:

- *UUID128 (name, byte1, byte2, ..., byte16)*

The*name* parameter is the user-friendly handle that references this UUID in the *gatt_db.h*file.

The 16 bytes are written in the *LSB-first* order each one using the 0xZZ format.

Note: On some occasions, it is desired to reuse an 128-bit UUID declared in *gatt_uuid128.h*. The 16 byte array is available through its friendly name and be accessed by including *gatt_db_handles.h* in the application. It is strongly advised to use it only in read-only operations. For example:

```
(gatt_uuid128.h)
UID128(uuid_service_wireless_uart, 0xE0, 0x1C, 0x4B, 0x5E, 0x1E, 0xEB, 0xA1, 0x5C, 0xEE, 0xF4, 0x5E,␣
↪0xBA, 0x00, 0x01, 0xFF, 0x01)
(app.c)
#include "gatt_db_handles.h"
.....
/* Start Service Discovery*/
BleServDisc_FindService(peerDeviceId, gBleUuidType128_c, (bleUuid_t*) &uuid_service_wireless_uart);
```

Parent topic: Creating static GATT database

Declaring a service There are two types of Services:

- *Primary Services*
- *Secondary Services* - these are only to be included by other Primary or Secondary Services

The Service declaration attribute has one of these UUIDs, as defined by the Bluetooth SIG:

- 0x2800 a.k.a. *«Primary Service»* - for a Primary Service declaration
- 0x2801 a.k.a. *«Secondary Service»* - for a Secondary Service declaration

The Service declaration attribute permissions are read-only and no authentication required. The Service declaration attribute value contains the *Service UUID*. The *Service Range* starts from the Service declaration and ends at the next service declaration. All the Characteristics declared within the Service Range are considered to belong to that Service. For a more comprehensive list of SIG defied UUID values, check ble_sig_defines.h.

Service declaration macros The following macros are to be used for declaring a Service:

- *PRIMARY_SERVICE (name, uuid16)*
  - Most often used.
  - The *name* parameter is common to all macros; it is a universal, user-friendly identifier for the generated attribute.
  - The *uuid16* is a 2-byte SIG-defined UUID, written in 0xZZZZ format.

- *PRIMARY_SERVICE_UUID32 (name, uuid32)*
  - This macro is used for a 4-byte, SIG-defined UUID, written in 0xZZZZZZZZ format.
- *PRIMARY_SERVICE_UUID128 (name, uuid128)*
  - The *uuid128* is the friendly name given to the custom UUID in the *gatt_uuid128.h* file.
- *SECONDARY _SERVICE (name, uuid16)*
- *SECONDARY_SERVICE_UUID32 (name, uuid32)*
- *SECONDARY _SERVICE_UUID128 (name, uuid128)*
  - All three are similar to Primary Service declarations.

Parent topic: Declaring a service

Include declaration macros Secondary Services are meant to be included by other Services, usually by Primary Services. Primary Services may also be included by other Primary Services. The inclusion is done using the Include declaration macro:

- *INCLUDE (service_name)*
  - The *service_name* parameter is the friendly name used to declare the Secondary Service.
  - This macro is used only for Secondary Services with a SIG-defined, 2-byte, Service UUID.
- *INCLUDE_CUSTOM (service_name)*
  - This macro is used for Secondary Services that have either a 4-byte UUID or a 16-byte UUID.

The effect of the service inclusion is that the *including* Service is considered to contain all the Characteristics of the *included* Service.

Parent topic: Declaring a service

Parent topic: Creating static GATT database

Declaring a characteristic A Characteristic must only be declared inside a Service. It belongs to the most recently declared Service, so the GATT Database must always begin with a Service declaration.

The Characteristic declaration attribute has the following UUID, as defined by the Bluetooth SIG:

- 0x2803 a.k.a. *«Characteristic»*

The Characteristic declaration attribute value contains:

- the *Characteristic UUID*
- the *Characteristic Value* 's declaration handle
- the *Characteristic Properties* – Read, Write, Notify, and so on. (1 byte of flags)

The *Characteristic Range*starts from the Characteristic declaration and ends before a new Characteristic or a Service declaration.

After the Characteristic declaration these follow:

- A *Characteristic Value* declaration (mandatory; immediately after the Characteristic declaration).
- Zero or more *Characteristic Descriptor* declarations.

Characteristic declaration macros The following macros are used to declare Characteristics:

- *CHARACTERISTIC (name, uuid16, properties)*
- *CHARACTERISTIC_UUID32 (name, uuid32, properties)*
- *CHARACTERISTIC _UUID128 (name, uuid128, properties)*

See Service declaration for *uuidXXX* parameter explanation.

The *properties* parameter is a bit mask. The flags are defined in the *gattCharacteristicPropertiesBitFields_t*.

Parent topic: Declaring a characteristic

Declaring characteristic values The Characteristic Value declaration immediately follows the Characteristic declaration and uses one of the following macros:

- *VALUE (name, uuid16, permissions, valueLength, valueByte1, valueByte2, ...)*
- *VALUE_UUID32 (name, uuid32, permissions, valueLength, valueByte1, valueByte2, ...)*
- *VALUE _UUID128(name, uuid128, permissions, valueLength, valueByte1, valueByte2, ...)*
  - See Declaring a service for description of the *uuidXXX* parameter.
  - The *permissions* parameter is a bit mask, whose flags are defined in *gattAttributePermissionsBitFields_t* .
  - The *valueLength* is the number of bytes to be allocated for the Characteristic Value. After this parameter, exactly [*valueLength*] bytes follow in 0xZZ format, representing the initial value of this Characteristic.

These macros are used to declare Characteristic Values of *fixed lengths*.

Some Characteristics have *variable length values*. For those, the following macros are used:

- *VALUE_VARLEN (name, uuid16, permissions, maximumValueLength, initialValueLength, valueByte1, valueByte2, ...)*
- *VALUE_UUID32_VARLEN (name, uuid32, permissions, maximumValueLength, initialValueLength, valueByte1, valueByte2, ...)*
- *VALUE_UUID128_VARLEN (name, uuid128, permissions, maximumValueLength, initialValueLength, valueByte1, valueByte2, ...)*
  - The number of bytes allocated for this Characteristic Value is *maximumValueLength*.
  - The number of *valueByteXXX* parameters shall be equal to *initialValueLength*.

Obviously, *initialValueLength* is, at most, equal to *maximumValueLength*.

Parent topic: Declaring a characteristic

Declaring characteristic descriptors Characteristic's Descriptors are declared after the Characteristic Value declaration and before the next Characteristic declaration.

The macros used to declare Characteristic Descriptors are very similar to those used to declare fixed-length Characteristic Values:

- *DESCRIPTOR (name, uuid16, permissions, descriptorValueLength, descriptorValueByte1, descriptorValueByte2, ...)*
- *DESCRIPTOR_UUID32 (name, uuid32, permissions, descriptorValueLength, descriptorValueByte1, descriptorValueByte2, ...)*
- *DESCRIPTOR_UUID128(name, uuid128, permissions, descriptorValueLength, descriptorValueByte1, descriptorValueByte2, ...)*

A special Characteristic Descriptor that is used very often is the *Client Characteristic Configuration Descriptor (CCCD)*. This is the descriptor where clients write some of the bits to activate Server notifications and/or indications. It has a reserved, 2-byte, SIG-defined UUID (0x2902), and its attribute value consists of only 1 byte (out of which 2 bits are used for configuration, the other 6 are reserved).

Because the CCCD appears very often in Characteristic definitions for standard Bluetooth Low Energy profiles, a special macro is used for CCCD declaration:

- *CCCD (name)*

This simple macro is basically equivalent to the following Descriptor declaration:

```
* DESCRIPTOR \(name, *
   *0x2902, *
   (gGattAttPermAccessReadable_c
   | gGattAttPermAccessWritable_c),
   2, 0x00, 0x00)
```

Parent topic: Declaring a characteristic

Parent topic: Creating static GATT database

Static GATT database definition examples The GAP Service must be present on any GATT Database. It has the Service UUID equal to 0x1800, *«GAP Service»*, and it contains three read-only Characteristics, no authentication required: *Device Name, Appearance,*and *Peripheral Preferred Connection Parameters*. These also have well defined UUIDs in the SIG documents.

Most of the demos also include the optional GATT Security Levels characteristic, which defines the highest security requirements of the GATT server when operating in a LE connection.

The definition for this Service is shown here:

```
PRIMARY_SERVICE(service_gap, 0x1800)
   CHARACTERISTIC(char_device_name, 0x2A00, (gGattCharPropRead_c) )
       VALUE(value_device_name, 0x2A00, (gGattAttPermAccessReadable_c), 6, "Sensor")
   CHARACTERISTIC(char_appearance, 0x2A01, (gGattCharPropRead_c) )
      VALUE(value_appearance, 0x2A01, (gGattAttPermAccessReadable_c), 2,
       0xC2, 0x03)
   CHARACTERISTIC(char_ppcp, 0x2A04, (gGattCharPropRead_c) )
       VALUE(value_ppcp, 0x2A04, (gGattAttPermAccessReadable_c), 8, 0x0A,
       0x00, 0x10, 0x00, 0x64, 0x00, 0xE2, 0x04)
   CHARACTERISTIC(char_security_levels, gBleSig_GattSecurityLevels_d,
      (gGattCharPropRead_c) )
       VALUE(value_security_levels, gBleSig_GattSecurityLevels_d,
       (gPermissionFlagReadable_c), 2, 0x01, 0x01)
```

Another often encountered Service is the Scan Parameters Service:

```
PRIMARY_SERVICE(service_scan_parameters, 0x1813)
     CHARACTERISTIC(char_scan_interval_window, 0x2A4F,          (gGattCharPropWriteWithoutRsp_
↪c) )
       VALUE(value_scan_interval_window, 0x2A4 (gGattAttPermAccessWritable), 4, 0x00, 0x00, 0x00,␣
↪0x00)
      CHARACTERISTIC(char_scan_refresh, 0x2A31, (gGattCharPropRead_c gGattCharPropNotify_c) )
       VALUE(value_scan_refresh, 0x2A31, (gGattAttPermAccessReadable_c), 1, 0x00) CCCD(cccd_scan_
↪refresh)
```

Note: All "user-friendly" names given in declarations are statically defined as *enum* members, numerically equal to the *attribute handle* of the declaration. This means that one of those names can be used in code wherever an attribute handle is required as a parameter of a function if *gatt_db_handles.h* is included in the application source file. For example, to write the value of the Scan Refresh Characteristic from the application-level code, use these instructions:

```
#include "gatt_db_handles.h"
...
uint8_t scan_refresh_value = 0x12;
GattDb_WriteAttribute(char_scan_refresh, 1, &scan_refresh_value);
```

For static database declarations, the 'attribute handle' is equal to the line number in the gatt_fb.h file, where the attribute is defined.

Parent topic: Creating static GATT database

Parent topic:*Creating GATT database*

Creating a GATT database dynamically To define a GATT Database at runtime, the *gGattDbDynamic_d* macro must be defined in *app_preinclude.h* with the value equal to 1.

Then, the application must use the APIs provided by the *gatt_db_dynamic.h* interface to add and remove Services and Characteristics as needed.

See Creating static GATT database for a detailed description of Service and Characteristic parameters.

Memory considerations The GATT Dynamic database module internally manages the memory allocation for the database. There are two ways to specify the memory configuration. The selection is done by setting gGattDynamicAttrSize_c and/or gGattDynamicValSize_c.

- *Statically pre-allocated memory area*
  - gGattDynamicAttrSize_c - the total size of the table of characteristics
  - gGattDynamicValSize_c - the total size of the values cumulated from all characteristics. If any of these macros is greater than 1 the application is responsible to decide upon the best value. In case the selected value is not big enough gBleOutOfMemory_c is returned by the GATT API calls.
- *Dynamic allocated memory area* If the gMemManagerLightExtendHeapAreaUsage define is set to 1 in the desired application, the whole available heap is used. In such as case, the user does not have to allocate space for the dynamic database. If this is not done, the user only needs to make sure that the MinimalHeapSize_c define is set to a high enough value considering all attributes and attribute values they want to add to the database, as well as other memory requirements the application might have. This method is used in case only several attributes are added dynamically. If multiple attributes are needed the method from *Statically pre-allocated memory area* above is recommended. This is because the heap gets fragmented with each adding of a new attribute.

Internally, two buffers are used by the dynamic database module: an attribute buffer and a value buffer. The attribute buffer size increases with the addition of each attribute to the database. The value buffer size increases depending on the UUID type and value lengths required by the application. The two buffers start with a minimum size and are reallocated whenever new requests to add entries are received and there is not enough available memory left. If the user removes these entries from the database, the memory reserved for those entries is not freed, but shifted, leaving room for new entries. Thus, an add operation after a remove operation might not necessarily reallocate the buffer if the new entries fit. The two buffers used by the Dynamic database module will not be available to the application until the user releases the database.

Parent topic: Creating a GATT database dynamically

Initialization and release Before anything can be added to the database, it must be initialized with an empty collection of attributes.

The *GattDbDynamic_Init()* API is automatically called by the *GattDb_Init()* implementation provided in the *gatt_database.c* source file. Application-specific code does not need to call this API again, unless at some point it destroys the database with *GattDb_ReleaseDatabase()*.

Parent topic: Creating a GATT database dynamically

Adding services The APIs that can be used to add Services are self-explanatory:

- *GattDbDynamic_AddPrimaryServiceDeclaration*
  - The Service UUID is specified as parameter.

    Memory requirements: one entry in the attribute buffer and UUID size in value buffer.
- *GattDbDynamic_AddSecondaryServiceDeclaration*
  - The Service UUID is specified as parameter.

    Memory requirements: one entry in the attribute buffer and UUID size in value buffer.
- *GattDbDynamic_AddIncludeDeclaration*
  - The Service UUID and handle range are specified as parameters.

    Memory requirements: one entry in the attribute buffer and 6 bytes in value buffer.

The functions have an optional out parameter *pOutHandle*. If its value is not NULL, the execution writes a 16-bit value in the pointed location representing the attribute handle of the added declaration. The application can use this handle as parameter in few *GattDbApp* APIs or in the Service removal functions.

At least one Service must be added before any Characteristic.

Parent topic: Creating a GATT database dynamically

Adding characteristics and descriptors The APIs for adding Characteristics and Descriptors are enumerated below:

- *GattDbDynamic_AddCharacteristicDeclarationAndValue*
  - The Characteristic UUID, properties, access permissions, and initial value are specified as parameters.
- *GattDbDynamic_AddCharacteristicDeclarationWithUniqueValue*
  - Multiple calls to this API allocate a unique 512-byte value buffer as an optimization for application that deal with large value buffers that do not always need to be stored separately.
- *GattDbDynamic_AddCharacteristicDescriptor*
  - The Descriptor UUID, access permissions and initial value are specified as parameters.
- *GattDbDynamic_AddCccd*
  - Shortcut for a CCCD.

Characteristics and descriptors are automatically added at the end of the database. Thus, a service declaration should be followed by all desired characteristic and descriptor definitions before adding a new service to the database.

Parent topic: Creating a GATT database dynamically

Removing services and characteristics To remove a Service or a Characteristic, the following APIs may be used, both of which only require the declaration handle as parameter:

- *GattDbDynamic_RemoveService*
- *GattDbDynamic_RemoveCharacteristic*

Parent topic: Creating a GATT database dynamically

Parent topic:*Creating GATT database*

Gatt caching

Service change feature The **service changed** feature applies to GATT servers and supports the service changed characteristic, dynamic databases, and handle value indications. The GATT clients that require to be notified for structural modifications on the database should write the CCCD of the Service Changed Characteristic on the server. The value of the Service Changed characteristic is represented by 2 handle values for the handle range affected by the modifications.

The changes that trigger a server database modification are represented by the following API calls:

- *GattDbDynamic_AddPrimaryServiceDeclaration*
- *GattDbDynamic_AddSecondaryServiceDeclaration*
- *GattDbDynamic_AddIncludeDeclaration*
- *GattDbDynamic_AddCharacteristicDeclarationAndValue*
- *GattDbDynamic_AddCharDescriptor*
- *GattDbDynamic_AddCccd*
- *GattDbDynamic_RemoveService*
- *GattDbDynamic_RemoveCharacteristic*

Those GATT server API calls update two internal handles to memorize the minimum and maximum range affected by the change.

After the GATT server database update is done, the application must call the GattDbDynamic_EndDatabaseUpdate() API. After this, a Service Changed indication is internally sent to each connected peer that has enabled these indications. The indication contains the handle range affected by the change.

. For bonded devices with whom the server is not currently in an active connection, the changes are buffered on the server and the peers are notified upon reconnection.

Parent topic: Gatt caching

Robust caching Robust caching is a feature where the server sends an error response to the client if the server does not consider the client to be aware of a database structural change. A server supporting robust caching provides the Client Supported Features, Database Hash, and Service Changed characteristics. To indicate support for robust caching, clients should write the robust caching bit (bit 0) of the Client Supported Features characteristic on the server. An example of the GAP service definition for a server with robust caching support is the following:

- *PRIMARY_SERVICE(service_gatt, gBleSig_GenericAttributeProfile_d)*
- *CHARACTERISTIC(char_service_changed, gBleSig_GattServiceChanged_d, (gGattCharPropIndicate_c))*
- *VALUE(value_service_changed, gBleSig_GattServiceChanged_d, (gPermissionNone_c), 4, 0x01, 0x00, 0xFF, 0xFF)*

- *CCCD(cccd_service_changed)*
- *CHARACTERISTIC(char_client_supported_features, gBleSig_GattClientSupportedFeatures_d, (gGattCharPropRead_c | gGattCharPropWrite_c))*
- *VALUE(value_client_supported_features, gBleSig_GattClientSupportedFeatures_d, (gPermissionFlagReadable_c | gPermissionFlagWritable_c), 8, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00)*
- *CHARACTERISTIC(char_database_hash, gBleSig_GattDatabaseHash_d, (gGattCharPropRead_c))*
- *VALUE(value_database_hash, gBleSig_GattDatabaseHash_d, (gPermissionFlagReadable_c), 16, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00)*

The Client Supported Features characteristic should be declared as an array. The array size is equal to the maximum number of connections, which can be active at one time, so that each possible peer can have its own value. The Server Supported Features characteristic value is automatically written by the Host to indicate robust caching support when appropriate. The Database Hash characteristic value is a 128-bit unsigned integer number where the computed hash value is written.

In order to enable the Robust Caching feature, the *gGattCaching_d* define should be enabled in the file app_preinclude.h. In order to enable automatic Host support for Robust Caching, the *gGattAutomaticRobustCachingSupport_d*define should also be enabled. This includes writing the Client Supported Features characteristic, writing the CCCD of the Service Changed characteristic, and reading the Database Hash after reconnecting with a previously bonded peer to check for new changes. If this define is not enabled, then it is up to the application to read and write all necessary characteristic for Robust Caching support.

The client state is kept on the server using the following enum:

```
typedef enum
{
gGattClientChangeUnaware_c = 0x00U, /*!< Gatt client state */
gGattClientStateChangePending_c = 0x01U, /*!< Gatt client state */
gGattClientChangeAware_c = 0x02U, /*!< Gatt client state */
} gattCachingClientState_c;
```

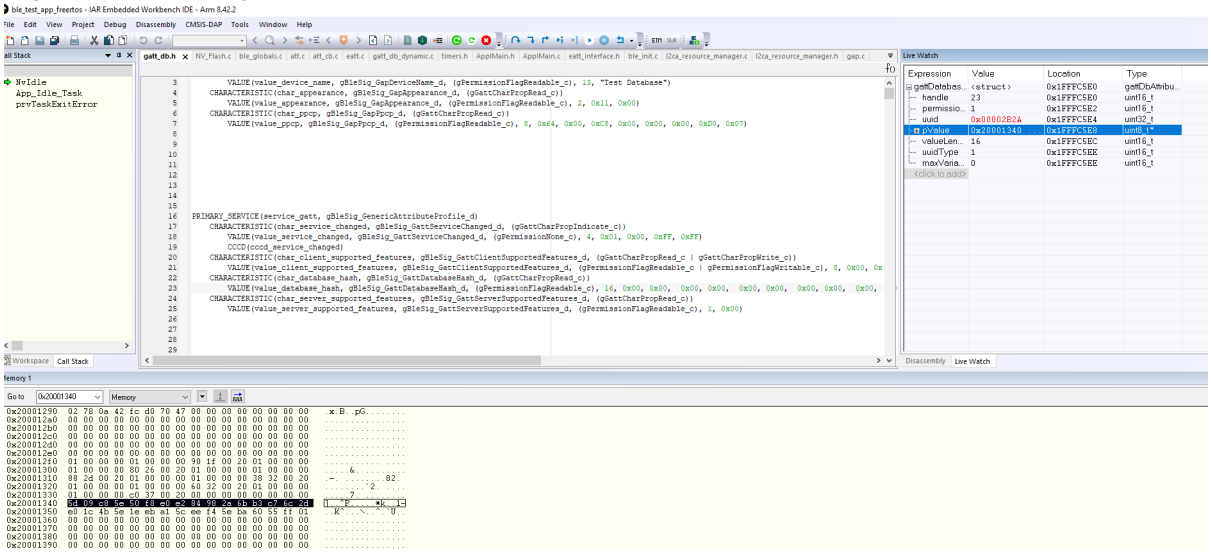
The initial state of a client without a trusted relationship is change-aware. The state of a client with a trusted relationship remains unchanged from the previous connection. However, in cases where the database has been updated since the last connection, the initial state is change-unaware. When a database update occurs, all connected clients become change unaware.

If a change-unaware client sends an ATT command, the server ignores it. For ATT requests received from a change-unaware client, the server sends an error response with the error code set to *gAttErrCodeDatabaseOutOfSync_c*. The server should also not send indications and notifications to change unaware clients, except for the Service Changed indication. The state of a client is verified by the GATT server before executing each command, request or sending any notifications or indications.

The following PDU types are an exception to this rule and do not generate an gAttErrCodeDatabaseOutOfSync_c error code:

- ATT_FIND_INFORMATION_REQ
- ATT_FIND_BY_TYPE_VALUE_REQ
- ATT_READ_BY_GROUP_TYPE_REQ
- ATT_EXECUTE_WRTIE

For a change unaware client to become change aware again, one of the following must happen:



- The client receives and confirms a Service Changed Indication.

- The server, upon receiving a request from a change unaware client, sends the client a response with the error code set to Database Out Of Sync and then the server receives another ATT request from the client.
- The change unaware client reads the Database Hash characteristic and then the server receives another ATT request from the client.

The function *GattDb_ComputeDatabaseHash()* is used by the server to compute the hash value and save its value in the database. The computation is done when a read request for the database hash characteristic is first received from a peer GATT client for dynamic databases.

For static databases, hash computation is disabled by default. If you have a static database and want to compute the database hash, then declare the following define to TRUE in app_preinclude.h: *gGattDbComputeHash_d*. By doing this, the hash value is computed during the host initialization. The value is written directly to the database as characteristic and it can be viewed in the memory, as see in the image below. Since static databases do not change in structure over time, this value remains constant, so it can be saved separately and written manually to memory if needed. See Figure 10 below.

Figure 10. Memory view of the Database Hash characteristic

On the client side, the *GattClient_GetDatabaseHash()* function is used to read the hash value from a peer GATT server. If the *gGattAutomaticRobustCachingSupport_c* define is enabled, then the following steps are executed automatically:

- Writing the Client Supported Features characteristic value to indicate robust caching support – set BIT0 to 1.
- Write the CCCD of the Service Changed characteristic.
- Read the initial value of the Database Hash characteristic and store it locally.

Otherwise, just the read request for the Database Hash characteristic is sent to the peer.

The following arrays and variables are used for the implementations of the robust caching and service changed features (declared in ble_globals.c):

```
/* Service changed indication buffer */
   gattHandleRange_t gServiceChangedIndicationStorage[gMaxBondedDevices_c];

/* client saved values for service changed characteristic and CCCD handles */
   uint16_t mActiveServiceChangedCharHandle[gAppMaxConnections_c] = {gGattDbInvalidHandle_d};
   uint16_t mServiceChangedCharHandle[gMaxBondedDevices_c] = {gGattDbInvalidHandle_d};
   uint16_t mActiveServiceChangedCCCDHandle[gAppMaxConnections_c] = {gGattDbInvalidHandle_d};

/* server values for its own service changed characteristic and CCCD handles */
```

(continues on next page)

(continued from previous page)

```
    uint16_t mServerServiceChangedCharHandle;
    uint16_t mServerServiceChangedCCCDHandle;

/* client state information for bonded and active clients */
    gattCachingClientState_c gGattClientState[gMaxBondedDevices_c] = {gGattClientChangeAware_c};
    gattCachingClientState_c gGattActiveClientState[gAppMaxConnections_c] = {gGattClientChangeAware_
↪c};

/* Database hash values - the client needs a hash value for each possible peer */
    uint8_t mGattActiveServerDatabaseHash[gGattDatabaseHashSize_c * gAppMaxConnections_c] = {0};
    uint8_t mGattServerDatabaseHash[gGattDatabaseHashSize_c * gMaxBondedDevices_c] = {0};

/* client supported features handles for active gatt servers */
    uint16_t gGattActiveClientSupportedFeaturesHandles[gAppMaxConnections_c] =
↪{gGattDbInvalidHandle_d};

/* client supported features information for bonded gatt clients */
    uint8_t gGattClientSupportedFeatures[gMaxBondedDevices_c] = {0U};

/* index of the database hash characteristic in the database */
    uint32_t mServerDatabaseHashIndex = gGattDbInvalidHandleIndex_d;

/* index of the client supported features characteristic in the database */
    uint32_t mServerClientSupportedFeatureIndex = gGattDbInvalidHandleIndex_d;
```

It is up to the application to save a local copy of the information from the server's database and to initiate service discovery only on the first connection or when it is informed of a change by the peer using Service Changed and Robust Caching.

If the *gGattAutomaticRobustCachingSupport_c* define is not set, it is up to the application to check the Server Supported Features characteristic value on the peer, to write the Client Supported Features characteristic value and to write the Service Changed CCCD.

Two new GATT procedures are introduced as part of the Robust Caching feature. Both should be treated according to the application needs in the GATT procedure callback of the application.

- *gGattProcSignalServiceDiscoveryComplete_c –*informs the application that the service discovery procedure has finished after reading the Database Hash value using the read using characteristic UUID procedure. The application procedure callback should call *BleServDisc_Finished()*on this event when robust caching is supported.
- *gGattProcUpdateDatabaseCopy_c –*informs the application that its database copy is no longer up to date and service discovery should be reperformed. Used when the client received an error response with the *gAttErrCodeDatabaseOutOfSync_c* opcode, when the local database hash value is found to be out of sync with the one on the server, or when a service changed indication is received from the server.

If service discovery is performed using our ble_service_discovery module, then the application should wait for the *gDiscoveryFinished_c* event before initiating its own GATT procedures. The application should also make sure to not initiate a second GATT procedure which requires a response from the peer before receiving a response to the first request it made.

Creating a Custom Profile This chapter describes how the user can create customizable functionality over the Bluetooth Low Energy Host Stack by defining profiles and services. The Temperature Profile, used by the Temperature Sensor and Collector applications, is used as a reference to explain the steps of building custom functionality.

Defining custom UUIDs The first step when defining a new service included in a profile is to define the custom 128-bit UUID for the service and the included characteristics. These values are defined in *gatt_uuid128.h*, which is located in the application folder. For example, the Temperature Profile uses the following UUID for the service:

```
/* Temperature */
UUID128(uuid_service_temperature, 0xfb ,0x34 ,0x9b ,0x5f ,0x80 ,0x00, 0x00, 0x80, 0x00, 0x10, 0x00, 0x02,␣
↪0x00, 0xfe, 0x00, 0x00)
```

The definition of the services and characteristics are made in *gattdb.h*, as explained in *Creating GATT database*. For more details on how to structure the database, see *Application Structure*.

Parent topic:*Creating a Custom Profile*

Creating service functionality All defined services in the SDK have a common template which helps the application to act accordingly.

The service locally stores the device identification for the connected client. This value is changed on subscription and non-subscription events.

```
/*! Temperature Service - Subscribed Client*/
static deviceId_t mTms_SubscribedClientId;
```

The service is initialized and changed by the application through a service configuration structure. It usually contains the service handle, initialization values for the service (for example, the initial temperature for the Temperature Service) and in some cases user-specific structures that can store saved measurements (for example, the Blood Pressure Service). Below is an example for the custom Temperature Service:

```
/*! Temperature Service - Configuration */
typedef struct tmsConfig_tag
{
    uint16_t serviceHandle ;
    int16_t initialTemperature ;
} tmsConfig_t ;
```

The initialization of the service is made by calling the start procedure. The function requires as input a pointer to the service configuration structure. This function is usually called when the application is initialized. It resets the static device identification for the subscribed client and initializes both dynamic and static characteristic values. An example for the Temperature Service (TMS) is shown below:

```
bleResult_t Tms_Start ( tmsConfig_t *pServiceConfig)
{
    mTms_SubscribedClientId = gInvalidDeviceId_c;
    return Tms_RecordTemperatureMeasurement (pServiceConfig-> serviceHandle ,
                                             pServiceConfig-> initialTemperature );
}
```

The service subscription is triggered when a device connects to the server. It requires the peer device identification as an input parameter to update the local variable. On disconnect, the unsubscribe function is called to reset the device identification. For the Temperature Service:

```
bleResult_t Tms_Subscribe ( deviceId_t deviceId)
{
    mTms_SubscribedClientId = deviceId;
    return gBleSuccess_c;
}
bleResult_t Tms_Unsubscribe (void)
{
    mTms_SubscribedClientId = gInvalidDeviceId_c;
```

(continues on next page)

(continued from previous page)

```
    return gBleSuccess_c;
}
```

Depending on the complexity of the service, the API implements additional functions. For the Temperature Service, there is only a temperature characteristic that is notifiable by the server. The API implements the record measurement function which saves the new measured value in the GATT database and send the notification to the client device if possible. The function needs the service handle and the new temperature value as input parameters:

```
bleResult_t Tms_RecordTemperatureMeasurement ( uint16_t serviceHandle, int16_t temperature)
{
    uint16_t handle;
    bleResult_t result;
    bleUuid_t uuid = Uuid16(gBleSig_Temperature_d);
    /* Get handle of Temperature characteristic */
    result = GattDb_FindCharValueHandleInService(serviceHandle,
        gBleUuidType16_c, &uuid, &handle);
    if (result != gBleSuccess_c)
        return result;
    /* Update characteristic value */
    result = GattDb_WriteAttribute(handle, sizeof( uint16_t ), ( uint8_t *)&temperature);
    if (result != gBleSuccess_c)
        return result;
    Hts_SendTemperatureMeasurementNotification(handle);
    return gBleSuccess_c;
}
```

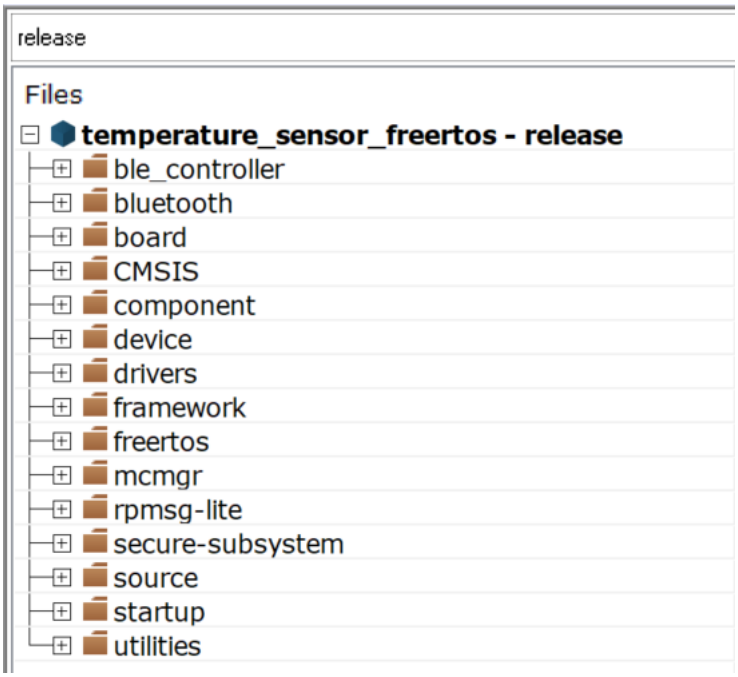
To accommodate some use cases where the service is reset, the stop function is called. The reset also implies a service unsubscribe. Below is an example for the Temperature Service:

```
bleResult_t Tms_Stop ( tmsConfig_t *pServiceConfig)
{
    return Tms_Unsubscribe();
}
```

Parent topic:*Creating a Custom Profile*

GATT client interactions The client side of the service, which includes the service discovery, notification configuration, attribute reads and others are left to be handled by the application. The application calls the GATT client APIs and reacts accordingly. The only exception for this rule is that the service interface declares the client configuration structure. This structure usually contains the service handle and the handles of all the characteristic values and descriptors discovered. Additionally it can contain values that the client can use to interact with the server. For the Temperature Service client, the structure is as follows:

```
/*! Temperature Client - Configuration */
typedef struct tmcConfig_tag
{
    uint16_t                hService;
    uint16_t                hTemperature ;
    uint16_t                hTempCccd ;
    uint16_t                hTempDesc ;
    gattDbCharPresFormat_t   tempFormat ;
} tmcConfig_t ;
```



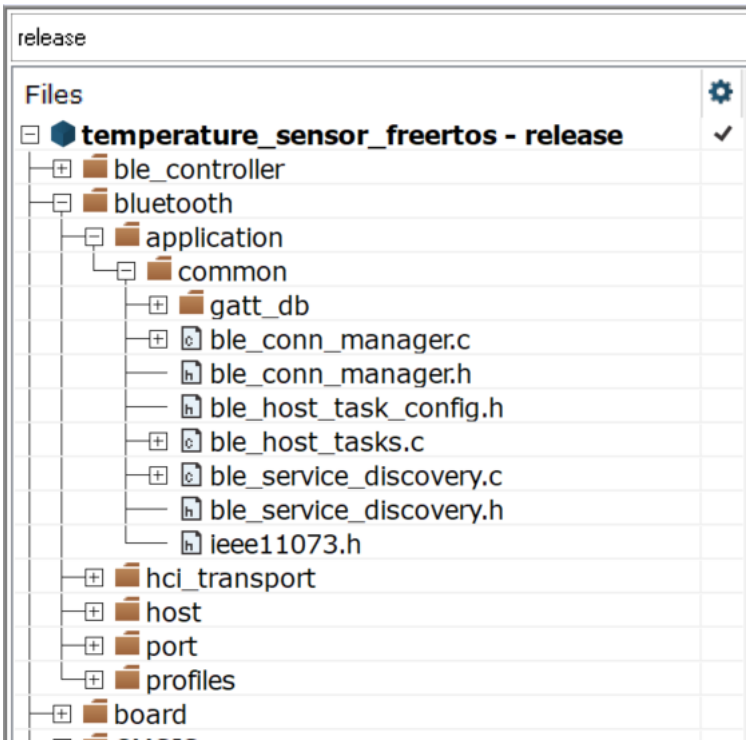
Parent topic:*Creating a Custom Profile*

Application Structure This chapter describes the organization of the Bluetooth Low Energy demo applications that can be found in the SDK. By familiarizing with the application structure,

the user is able to quickly adapt its design to an existing demo or create a new application.

The Temperature Sensor application is used as a reference to showcase the architecture.

Folder structure The Figure shows the application folder structure.

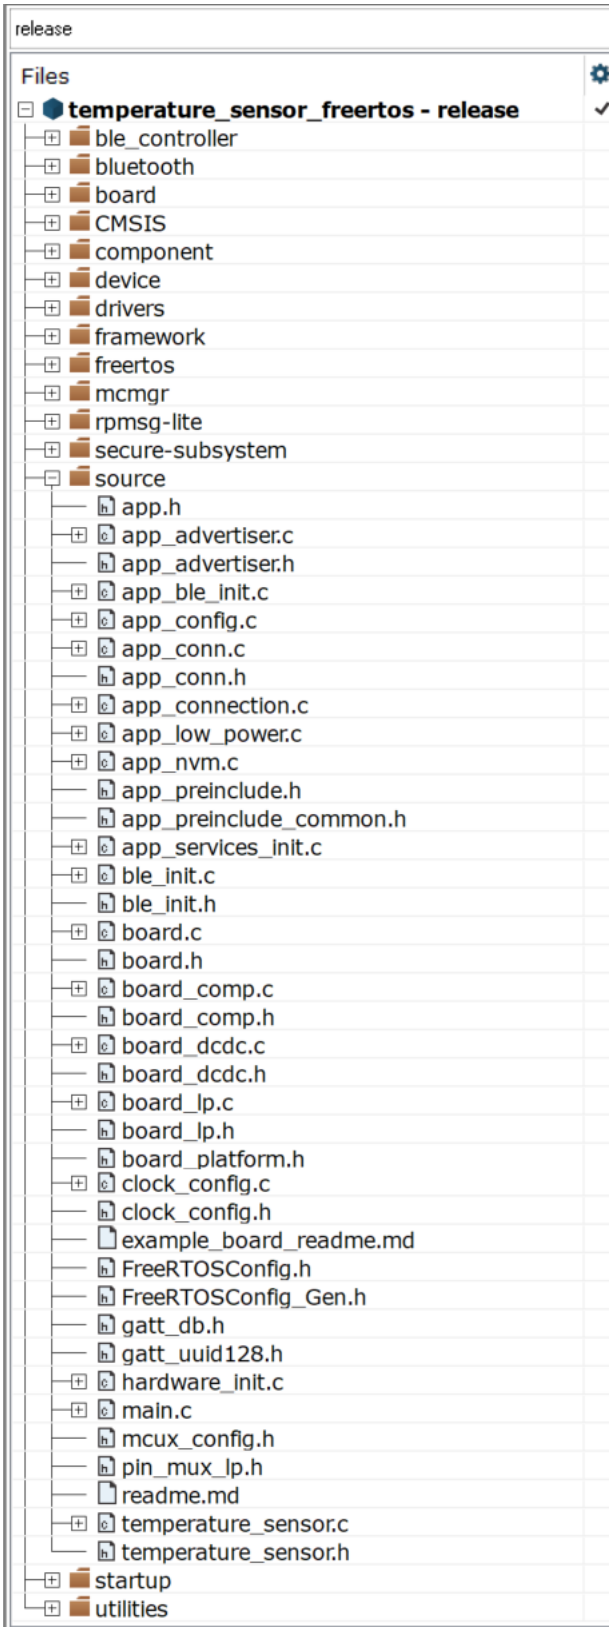


Application Folder structure in workspace

The *app* folder follows a specific structure which is recommended for any application developed using the Bluetooth Low Energy Host Stack:

- The *common* group contains the application framework shared by all profiles and demo applications:
  - Bluetooth Low Energy Connection Manager
  - Bluetooth Service Discovery Manager
  - Bluetooth Low Energy Stack and Task Initialization and Configuration
  - GATT Database

Common Group

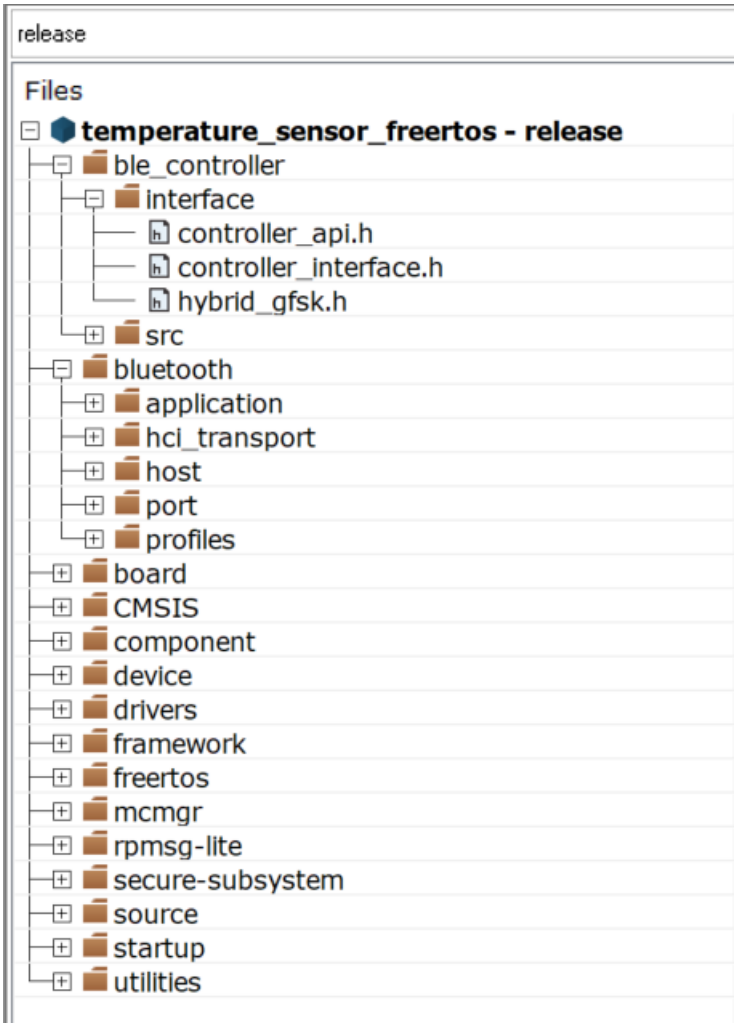


- The *source* group contains code specific to the Temperature Sensor application.

  In the following examples, *app.c* is used as a placeholder for the main application source file. In the case of Temperature Sensor, it is *temperature_sensor.c*.

  The source group also contains files which aid with the handling of Host events and framework related functionality. These are: *app_conn.c*/*app_conn.h*, *app_advertiser.c*, *app_connection.c*, *app_scanner.c*, *app_nvm.c*, and *app_low_power.c*. These files do not allow the application to implement its own state machines, unless application-specific functionality is required. For example, the application is restricted from setting advertising parameters and starting advertising, unless certain application-specific functionalities, such as UI related updates are required.

Source Group



The *bluetooth* folder/group contains:

- The *host/interface*, and *host/config*. These are public interfaces and configuration files for the Host. The functionality is included in the library located in the *host/lib* subfolder. The folder is not shown in the IAR project structure, but added into the toolchain linker settings under the library category.
- *bluetooth/profiles* contains profile-specific code; it is used by each demo application of stan-

dard profiles.

The *ble_controller* folder/group contains:

- The *controller/interface*. These are public interfaces and configuration files for the Controller.

Bluetooth and Controller Groups

The framework and component folders/groups contain framework components used by the demo applications. For additional information, see the *Connectivity Framework Reference Manual*.

The *freertos* folder contains sources for the supported operating system.

Parent topic:*Application Structure*

Application main framework The Application Main module contains common code used by all the applications, such as:

- The Main Task
- Messaging framework between the Bluetooth LE Host Stack Task and the Application Task

Start task The Start Task (*start_task*) is the first task created by the operating system and is also the one that initializes the rest of the system. It initializes framework components (Memory Manager, Timers Manager etc.) and it calls *BluetoothLEHost_AppInit* from *app.c*, which is used to initialize the Bluetooth LE Host Stack as well as peripheral drivers specific to the implemented application.

The function calls *BluetoothLEHost_HandleMessages*, which represents the Application Task and is used to process events and messages from the Host Stack.

The stack size and priority of the main task are defined in *fsl_os_abstraction_config.h*:

```
#ifndef gMainThreadStackSize_c
#define gMainThreadStackSize_c 1024
#endif
#ifndef gMainThreadPriority_c
#define gMainThreadPriority_c 7
#endif
```

Parent topic: Application main framework

Application messaging The module contains a wrapper that is used to create messages for events generated by the Bluetooth LE Host Stack in the Host Task context. The wrapper also sends them to be processed by the application in the context of the Application Task.

For example, connection events generated by the Host are received by *App_ConnectionCallback*. The function creates a message, places it in the Host to Application queue and signals the Application with *gAppEvtMsgFromHostStack_c*. The Application Task de-queues the message and calls *App_HandleHostMessageInput*, which calls the corresponding callback implemented the application-specific code (*app.c*), in this example: *BleApp_ConnectionCallback*.

It is strongly recommended that the application developer uses the *app.c* module to add custom code on this type of callbacks.

Parent topic: Application main framework

Parent topic:*Application Structure*

Bluetooth LE Connection Manager The connection manager is a helper module that contains common application configurations and interactions with the Bluetooth LE Host Stack. It implements the following events and methods:

- Host Stack GAP Generic Event
- Host Stack Connection Event on both GAP Peripheral and GAP Central configuration
- Host Stack configuration for GAP Peripheral or GAP Central

GAP generic event The GAP Generic Event is triggered by the Bluetooth LE Host Stack and sent to the application via the generic callback. Before any application-specific interactions, the Connection Manager callback is called to handle common application events, such as device address storage.

```
void BleApp_GenericCallback ( gapGenericEvent_t * pGenericEvent)
{
  /* Call Bluetooth Low Energy Conn Manager */
  BleConnManager_GenericEvent(pGenericEvent);
  switch (pGenericEvent-> eventType )
  {
    ...
  }
}
```

In the **BleConnManager_GenericEvent** function, local keys are generated.

- The local LTK, IRK, and CSRK as well as the EDIV and RAND are obtained hashing over the board's UID and stored in RAM as plain-text every time the **gInitializationComplete_c** event is received.

- In **Advanced Secure** mode, local IRK and CSRK are generated using the EdgeLock Secure Enclave and stored into a dedicated NVM data set as ELKE blobs (40 bytes blob encrypted using unique die key) on the first gInitializationComplete_c event received.

The NBU Decryption key for IRK is generated and distributed to the NBU over the private key bus. The EIRK blob (16 bytes blob which can be decrypted only by NBU hardware using NBU Decryption key for IRK) is generated from the IRK ELKE blob and stored in the RAM to be used for controller privacy on every gInitializationComplete_c event received. For the host privacy, the ELKE IRK blob is used instead. For details, refer to the section “Advanced security capabilities”.

Parent topic: Bluetooth LE Connection Manager

GAP configuration The GAP Central or Peripheral Configuration is used to create common configurations (such as setting the public address, registering the security requirements, adding the addresses of bonded devices in the Controller Filter Accept List), which can be customized by the application afterwards. It is called inside the *BluetoothLEHost_Initialized callback* function, before any application-specific configuration, as shown in the example code below.

```
static void BluetoothLEHost_Initialized()
{
    /* Set common GAP configuration */
    BleConnManager_GapCommonConfig();
    ...
}
```

Parent topic: Bluetooth LE Connection Manager

GAP connection event The GAP Connection Event is triggered by the Host Stack and sent to the application via the connection callback. Before any application-specific interactions, the Connection Manager callback is called to handle common application events, such as device connect, disconnect or pairing-related requests. It is called inside the registered connection such as shown below:

```
static voidBle App_ConnectionCallback ( deviceId_t peerDeviceId, gapConnectionEvent_t *␣
↪pConnectionEvent)
{
    /* Connection Manager to handle Host Stack interactions */
    BleConnManager_GapPeripheralEvent(peerDeviceId, pConnectionEvent);
    switch (pConnectionEvent-> eventType )
    {
        ...
    }
}
```

It is strongly recommended that the application developer uses the app.c module to add custom code.

Parent topic: Bluetooth LE Connection Manager

Privacy To enable or disable Privacy, the following APIs may be used:

```
bleResult_t
 BleConnManager_EnablePrivacy(void);
```

```
bleResult_t
 BleConnManager_DisablePrivacy(void);
```

The function BleConnManager_EnablePrivacy calls *BleConnManager_ManagePrivacyInternal* after checking if the privacy is enabled.

```
static bleResult_t
BleConnManager_ManagePrivacyInternal
(bool_t bCheckNewBond);
```

If the privacy feature is supported (*gAppUsePrivacy_d = 1*), the Connection Manager activates Controller Privacy or Host Privacy depending on the board capabilities.

The *bCheckNewBond* is a boolean that tells the Manager whether it should check or not if a bond between the devices already exists.

In order to update the identity information after a bond is added or removed privacy should be disabled and enabled. For pairing with bonding this is done automatically in *ble_conn_manager*. In case the application adds or removes a bond through the GAP API, it should also disable and enable privacy.

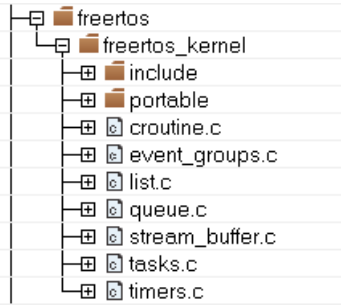
Parent topic: Bluetooth LE Connection Manager

Parent topic:*Application Structure*

GATT database The *gatt_db* contains a set of header files grouped in the *macros* subfolder. These macros are used for static code generation for the GATT Database by expanding the contents of the *gatt_db.h* file in different ways. *Creating GATT database* explains how to write the *gatt_db.h* file using user-friendly macros that define the GATT database.

At application compile time, the *gatt_database.c* file is populated with enumerations, structures, and initialization code used to allocate and properly populate the GATT database. In this way, the *gattDatabase*array and the *gGattDbAttributeCount_c* variable (see GATT database) are created and properly initialized.

Note: Do not modify any of the files contained in the *gatt_db* folder and its subfolder.



To complete the GATT database initialization, this demo application includes the required `gatt_db.h` and `gatt_uuid128.h` files in its specific application folder, along with other profile-specific configuration and code files.

Parent topic:*Application Structure*

RTOS specifics

Operating system selection The SDK offers different projects for each supported operating system (FreeRTOS OS) and for BareMetal configuration. To switch between systems, the user needs to switch the workspace.

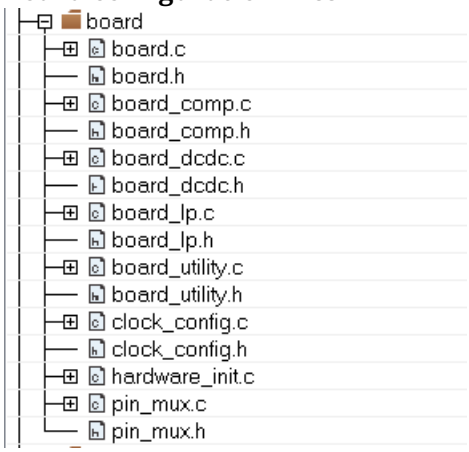
The RTOS source code is found in the SDK package and is linked in the workspace in the *freertos* virtual folder, as shown in Figure:

Location of FreeRTOS source code in workspace

Parent topic:RTOS specifics

Bluetooth LE Host task configuration Application developers are provided with two files for RTOS task initialization:

- *ble_host_task_config.h*, and *ble_host_tasks.c* for the Host.



Reusing these files is recommended because they perform all the necessary RTOS-related work. The application developer must only modify the macros from **_config.h* files whenever tasks need a bigger stack size or different priority settings. The new values should be overridden in the *app_preinclude.h* file.

Parent topic:RTOS specifics

Parent topic:*Application Structure*

Board configuration The configuration files for the supported boards can be found in the *board* folder, as shown in Figure. The files contain clock and pin configurations that are used by the drivers. The user can customize the board files by modifying the configuration of the pins and clock source according to his design.

Board configuration files

Parent topic:*Application Structure*

Bluetooth Low Energy initialization The *ble_init.h* and *ble_init.c* files contain the declaration and the implementation of the following function:

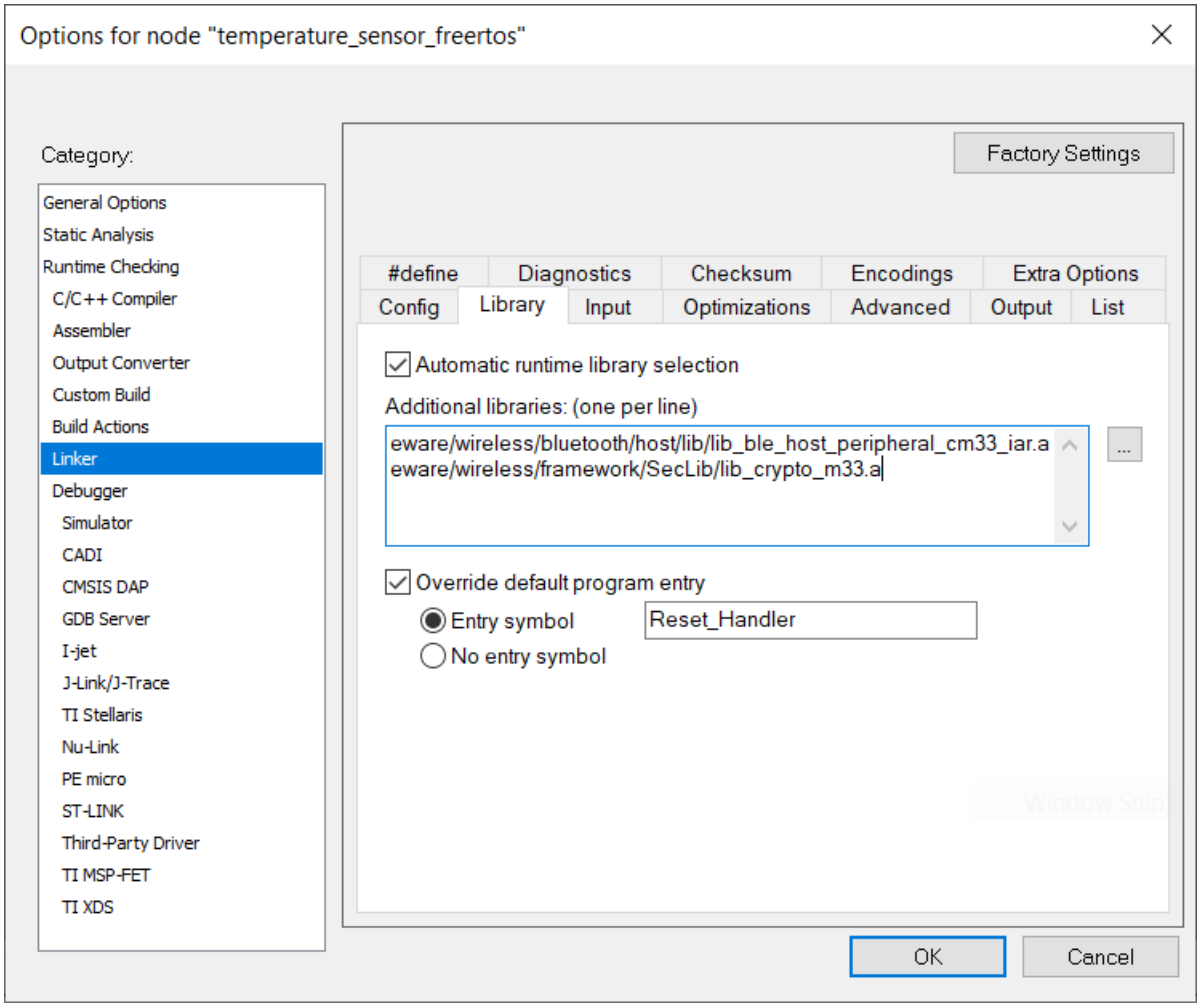
```
bleResult_t Ble_Initialize
(
    gapGenericCallback_t gapGenericCallback
)
{
#if defined(gUseHciTransportDownward_d) && gUseHciTransportDownward_d
    /* HCI Transport Init */
    if (gHciSuccess_c != Hcit_Init(Ble_HciRecvFromIsr))
    {
        return gHciTransportError_c;
    }
#if defined(KW45B41Z83_SERIES) || \
    defined(KW45B41Z82_SERIES) || \
    defined(K32W1480_SERIES)
    /*
     * Set BD Address in Controller. Must be done after HCI init
     * and before Host init.
     */
      Ble_SetBDAddr();
#endif /* KW45B41Z83_SERIES */
    /* Check for available memory storage */
```

(continues on next page)

(continued from previous page)

```
    if (!Ble_CheckMemoryStorage())
    {
        return gBleOutOfMemory_c;
    }
    /* Bluetooth Low Energy Host Tasks Init */
    if (KOSA_StatusSuccess != Ble_HostTaskInit())
    {
        return gBleOsError_c;
    }
    /* Bluetooth Low Energy Host Stack Init */
    return Ble_HostInitialize(gapGenericCallback, Hcit_SendPacket);
#elif defined(gUseHciTransportUpward_d) && gUseHciTransportUpward_d
#else /* gUseHciTransportUpward_d */
#endif /* gUseHciTransportUpward_d */
}
```

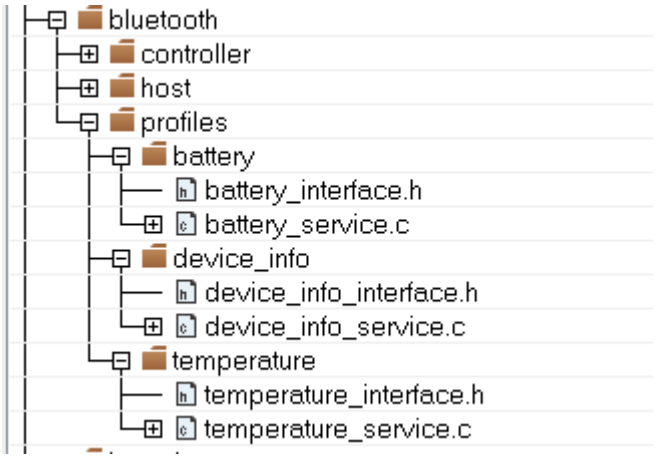
Note: This function should be used by your application because it correctly performs all the necessary Bluetooth Low Energy initialization.



Step-by-step analysis is provided below:

1. First, the HCI interface is initialized by calling *Hcit_Init*. This initializes communication between the Host and the Controller.
2. After setting the BD address into the Controller (Ble_SetBDAddr) and performing memory validation checks (*Ble_CheckMemoryStorage*), the Host task is initialized by calling *Ble_HostTaskInit*.
3. Finally the *Ble_HostInitialize* function initializes the Host with the transport packet transmit function used as the *hciHostToControllerInterface_t parameter*.

Parent topic:*Application Structure*



Bluetooth Low Energy Host Stack configuration The Bluetooth LE Host Stack libraries are found in the middleware/wireless/bluetooth/host/lib folder. The user should add the best matching library for its use case to the linker options of its project.

For example, the temperature sensor uses the Peripheral Host Stack library, as shown in Figure below:

Parent topic:*Application Structure*

Profile configuration The implemented profiles and services are located in *middleware/wireless/bluetooth/profiles* folder. The application links every service source file and interface it needs to implement the profile. For example, for the Temperature Sensor the tree looks as shown Figure:

The Temperature Profile implements the custom Temperature service, the Battery, and Device Information services.

Application code The application folder contains the following modules:

- *app.c* and *app.h*. This module stores the application-specific functionality (APIs for specific triggers, handling of peripherals, callbacks from the stack, handling of low power, and so on).

Before initializing the Bluetooth LE Host Stack, the start task calls *BluetoothLEHost_AppInit*. This function initializes application specific functionality before initializing the Bluetooth LE Host Stack by calling *BluetoothLEHost_Init*.

After the stack is initialized, the *BluetoothLEHost_Initialized* callback is called. The function contains configurations made to the Bluetooth LE Host Stack after the initialization. This includes registering callbacks, setting security for services, starting services, allocating timers, adding devices to the Filter Accept List, and so on. For example, the Temperature Sensor configures the following:

```
static void BluetoothLEHost_Initialized(void)
{
  /* Common GAP configuration */
    BleConnManager_GapCommonConfig();

  /* Register for callbacks*/
    (void)App_RegisterGattServerCallback(BleApp_GattServerCallback);

    mAdvState.advOn = FALSE;

  /* Start services */
    SENSORS_TriggerTemperatureMeasurement();
    (void)SENSORS_RefreshTemperatureValue();
    /* Multiply temperature value by 10. SENSORS_GetTemperature() reports temperature
    value in tenths of degrees Celsius. Temperature characteristic value is degrees
    Celsius with a resolution of 0.01 degrees Celsius (GATT Specification
    Supplement v6). */
    tmsServiceConfig.initialTemperature = (int16_t)(10 * SENSORS_GetTemperature());
    (void)Tms_Start(&tmsServiceConfig);

    basServiceConfig.batteryLevel = SENSORS_GetBatteryLevel();
    (void)Bas_Start(&basServiceConfig);
    (void)Dis_Start(&disServiceConfig);

  /* Allocate application timer */
    (void)TM_Open(appTimerId);

    AppPrintString("\r\nTemperature sensor -> Press switch to start advertising.\r\n");
}
```

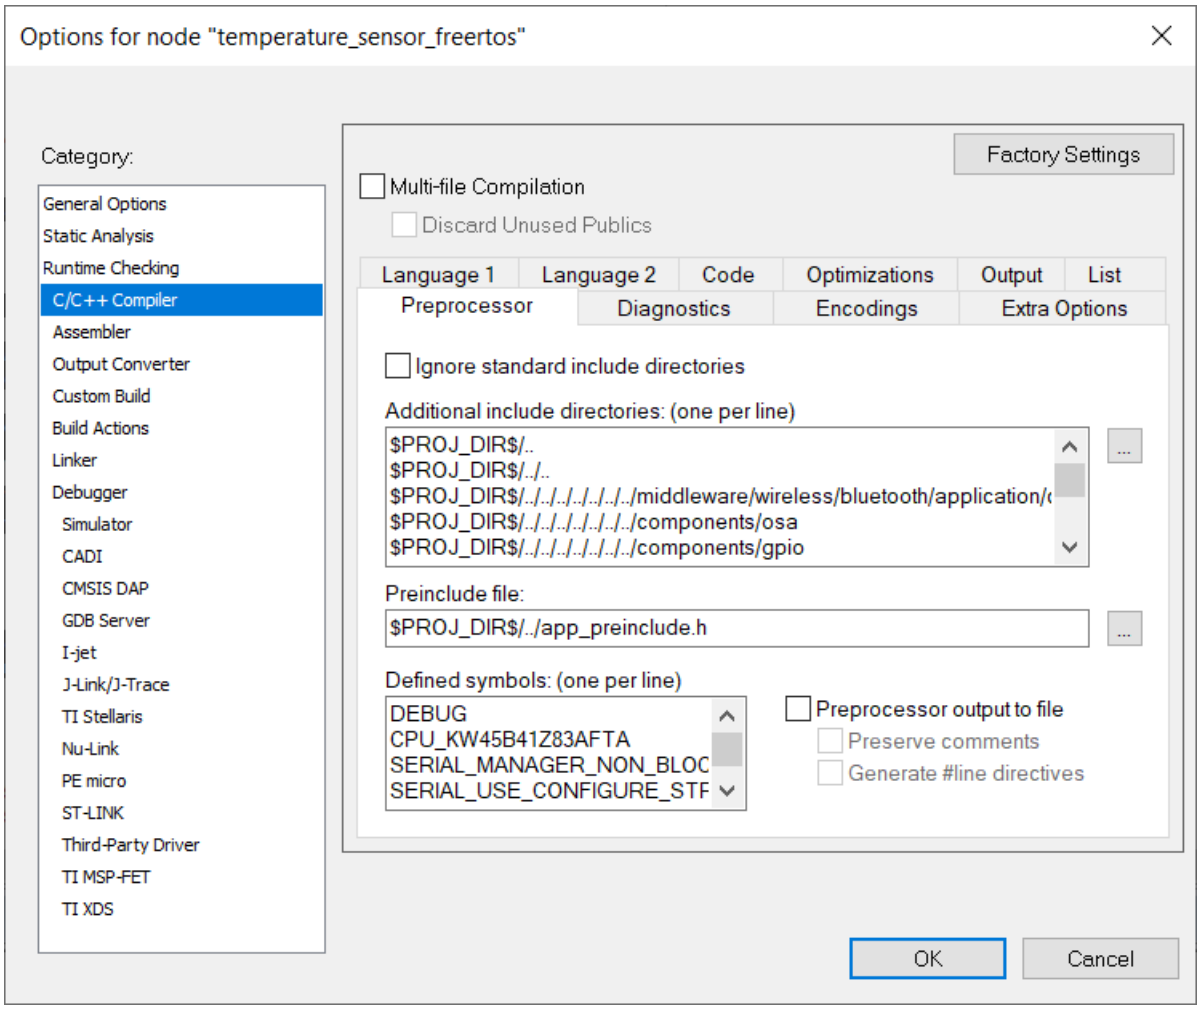
To start the application functionality, BleApp_Start() function is called. This function usually contains code to start advertising for sensor nodes or scanning for central devices. In the example of the Temperature Sensor, the function is the following:

```
static void BleApp_Start(void)
{
    Led1On();

    if (mPeerDeviceId == gInvalidDeviceId_c)
    {
      /* Device is not connected and not advertising */
        if (!mAdvState.advOn)
        {
            /* Set advertising parameters, advertising to start on gAdvertisingParametersSetupComplete_c */
            BleApp_Advertise();
        }
    }
```

(continues on next page)

(continued from previous page)



```
    else
    {
        /* Device is connected, send temperature value */
        BleApp_SendTemperature();
    }
}
```

- *app_config.c.* This file contains data structures that are used to configure the stack.

This includes advertising data, scanning data, connection parameters, advertising parameters, SMP keys, security requirements, and so on.

- *app_preinclude.h.*

This header file contains macros to override the default configuration of any module in the application. It is added as a preinclude file in the preprocessor command line in IAR, as shown in Figure:

- *gatt_db.h* and *gatt_uuid128.h.* The two header files contain the definition of the GATT database and the custom UUIDs used by the application. See *Creating GATT database* for more information.

Parent topic: Profile configuration

Parent topic:*Application Structure*

Multiple connections Applications can be configured to support multiple connections. To allow multiple connections, the *gAppMaxConnections_c* must be set to a value up to the maximum number of connections (*this value is chip-specific*). Refer to the chip documentation for the supported number of connections.

The application can save information about the peer devices it connects to according to the value of *gAppMaxConnections_c*. The Bluetooth Low Energy profile associated with the application use case must be instantiated to support the use of its functionality for each peer device. When handling multiple connections, the applications can behave as either the GAP central, GAP peripheral, or both at the same time. It is up to the application code to decide whether to start the advertising or scanning before creating the next connection. The supported combinations enable a device to connect as a peripheral to multiple centrals, as a central to multiple peripherals, or for it to be a central for some peers and a peripheral to others. The demo applications provide this functionality as an example of exercising multiple connection support. In such applications, the GAP role can be changed from central to peripheral and the information is saved for each peer device.

Parent topic:*Application Structure*

Bluetooth address generation BD_ADDR is represented by 48 bits that uniquely identify a device and consist of a 24-bit OUI (Organizationally Unique Identifier) and a 24-bit random part that varies between devices. There are multiple options of storing and using the BD_ADDR. Depending on the chip, it may be read from a device specific register (if supported), from the global hardware parameters stored in the flash, or generated randomly based on the processor-unique identifier. The demo applications provide a combination of the last two options. The *Ble_SetBDAddr* function is called during the initialization process, after initializing HCI and before initializing the Bluetooth LE Host Stack. The global hardware parameters are read from the flash. If a useful value is found, it is used as the BD address. If the found value is all 0xFFs, an address is generated by concatenating the OUI configured at compile time with three randomly generated bytes. The result is stored in the hardware parameters for future use and then set into the Controller. The Bluetooth LE Host Stack uses little-endian format to represent all addresses, in compliance with the Bluetooth Core Specification.

Parent topic:*Application Structure*

Repeated attempts Applications can be configured to enable protection against repeated Pairing Requests/Peripheral Security Requests coming from the same device. This is to prevent an intruder from repeating the pairing process with a large number of different keys in order to extract information about the local device's private key. If this feature is enabled, after a pairing procedure fails, another attempt to pair coming from the same device is allowed only after a specific time period has passed. For each failure, the waiting period doubles up until a maximum period.

The following *app_preinclude.h* macros support this feature:

- gRepeatedAttempts_d
  - Set to 1 to enable the feature. By default, it is disabled (0).
- gRepeatedAttemptsNoOfDevices_c
  - Number of remote devices to keep track of. By default, the value is 4.
  - If a new device needs to be added and the list is full, one of the oldest entries will be replaced.
- gRepeatedAttemptsTimeoutMin_c
  - Minimum waiting period in seconds – default 10.
- gRepeatedAttemptsTimeoutMax_c

  - Maximum waiting period in seconds – default 640. The waiting period doubles after each failed pairing with the same device.

Parent topic:*Application Structure*

Advanced Secure Mode This section describes the advanced security capabilities of the Bluetooth LE Host Stack which are available on the KW45/K32W1/KW47/MCXW72 platform via the EdgeLock Secure Enclave (ELKE).

The security capabilities are enabled at application, Host and Controller level by setting Advanced Secure Mode to active. To do this, the user must set the *gAppSecureMode_d* macro to *1* in the project's *app_preinclude.h* file. This macro is defined by default as *0* in *app_preinclude_common.h*:

```
#if (gAppSecureMode_d == 1U)
#define gSecLibSssUseEncryptedKeys_d     (1U)
#define gHostSecureMode_d                (1U)
#else
#define gHostSecureMode_d                (0U)
#endif
```

At application level, when Advanced Secure Mode is enabled, the security mode and level for pairing is automatically enforced as Mode 1 Level 4, ensuring LE Secure Connections pairing. Legacy pairing is not supported in this mode.

When enabled, the main benefit of Advanced Secure Mode is the secured storage and handling of Bluetooth LE security keys. The EdgeLock Secure Enclave is capable of generating, importing, and exporting security keys as plain text or as encrypted blobs. All encrypted blobs are created by the EdgeLock Secure Enclave using a die unique key, which makes them impossible to decrypt by devices other than the one that created them. The Bluetooth LE security keys are managed in Advanced Secure Mode as follows:

- IRK
  - The peer IRKs received after pairing and bonding are no longer stored into NVM as plaintext, but as encrypted blobs 40 bytes in length (or ELKE blobs). They can still be retrieved and converted to plaintext.
  - The local IRK is no longer generated using the default method of hashing over the board's UID at every startup. It is instead generated once using the EdgeLock Secure Enclave and stored into a new NVM dataset as an ELKE blob.
  - Local and peer IRKs are no longer transmitted through HCI in plaintext but as EIRK (Encrypted IRK) blobs, 16 bytes in length, which can be decrypted by the Controller.
- LTK
  - The LTK is no longer stored into NVM as plaintext, but as an ELKE blob. Furthermore, the plaintext of the LTK is never available to the Host/application. Generating the LTK via the ECDH process and generating the Session Key for individual connections is done by the Host via the EdgeLock Secure Enclave and custom vendor HCI messages which are transparent to the application.
- CSRK
  - The local CSRK is no longer generated using the default method of hashing over the board's UID at every startup. It is instead generated once using the EdgeLock Secure Enclave and stored into a new NVM dataset as an ELKE blob.

At startup, Advanced Secure Mode for the Controller is enabled dynamically by calling:

```
#if (defined(gAppSecureMode_d) && (gAppSecureMode_d > 0U))
    (void) PLATFORM_EnableBleSecureKeyManagement();
#endif
```

This call can be found in BluetoothLEHost_Init, as part of the initialization sequence.

Additional considerations

- The Gap_LoadKeys API will return the IRK in plaintext, having converted it from the ELKE blob which is stored in the NVM. However, it cannot convert the LTK to plaintext - it will thus return the LTK in ELKE blob form.
- As mentioned in the section above, the plaintext LTK is never available. Generating the Session Key for individual connections is done via the EdgeLock Secure Enclave by the Host, using the LTK in ELKE blob form. The Session Key is passed to the Controller via a custom vendor HCI message. Be aware that the content of the HCI_LE_Long_Term_Key_Request_Reply command is not the actual LTK and cannot be used for debugging.
- The Host works with IRKs in ELKE blob form, therefore APIs such as Gap_EnableHostPrivacy and Gap_CreateRandomAddress take ELKE blobs as arguments. The Controller works with IRKs in EIRK blob form, therefore the Gap_EnableControllerPrivacy takes an EIRK blob as argument. This management is done in *ble_conn_manager.c* when Advanced Secure Mode is enabled.

Parent topic:*Application Structure*

Low-Power Management

System considerations The KW45/K32W1 has a dual-core architecture and has two separated power domains:

- The main domain for the Cortex M33
- The Radio domain which comprises the Cortex M3 core and the NBU (Narrow Band Unit).

The two power domains can go into or exit independently different low-power modes, namely Wait for instruction (WFI), Deep-sleep mode, Power-down mode, and Deep Power-down mode.

In Wait For Interrupt (WFI) mode, the CPU core is powered ON but is in an idle mode with the clock turned OFF.

In Deep Sleep mode, the fast clock is turned off, and the CPU along with the main power domain are placed into a retention state, with the voltage being scaled down to support state retention only. As no high frequency clock runs in this mode, the voltage applied on the power domain can be reduced to reduce leakage on the hardware logic. This reduces the overall power consumption in the Deep Sleep mode. When waking up from Deep Sleep mode, the core voltage is increased back to nominal voltage, the fast clock (FRO) is turned back on, and the peripheral in this domain can be reused as normal.

In Power-down mode, both the clock, and power are shut off to the CPU and the main peripheral domain. SRAM is retained, but register values are lost. The SDK power manager handles the restore of the processor registers and dependencies such as interrupt controller and similar ones transparently from the application.

In Deep Power-down mode the SRAM is not retained. This is the lowest power mode available. It is exited through the reset sequence.

Parent topic:*Low-Power Management*

When/how to enter low power To enable low power at application level, the gAppLowpowerEnabled_d define should be set to 1 in app_preinclude.h file.

The system should enter low power when the entire system is idle, and all software layers agree on that. The device enters low power by calling the PWR_EnterLowPower function.

For FreeRTOS applications, the low-power entry point is placed in the FreeRTOS idle task, which has the lowest priority in the system. From that task, the vPortSuppressTicksAndSleep function is called, which at its turn, calls the PWR_EnterLowPower to enter low power.

For the BareMetal examples, the application low power entry point is placed in the main function and is called when there are no messages to be processed by other tasks.

The wake-up sources that can be configured for the application are UART or button. Note that Low-power timer wake-up source and wake-up from the Radio domain are directly enabled from the Connectivity framework.

Each software layer/entity running on the system can prevent it from entering low power by calling *PWR_LowPowerEnterCritical* function. The system stays awake until all software layers that called *PWR_LowPowerEnterCritical* call back *PWR_LowPowerExitCritical* and the system reaches the low-power entry point.

When going to low power, the SDK Power Manager selects the best low-power mode that fits all the constraints.

The default low-power mode for each application is Deep-sleep mode. Users can change the behavior by setting a new low-power constraint for the application.

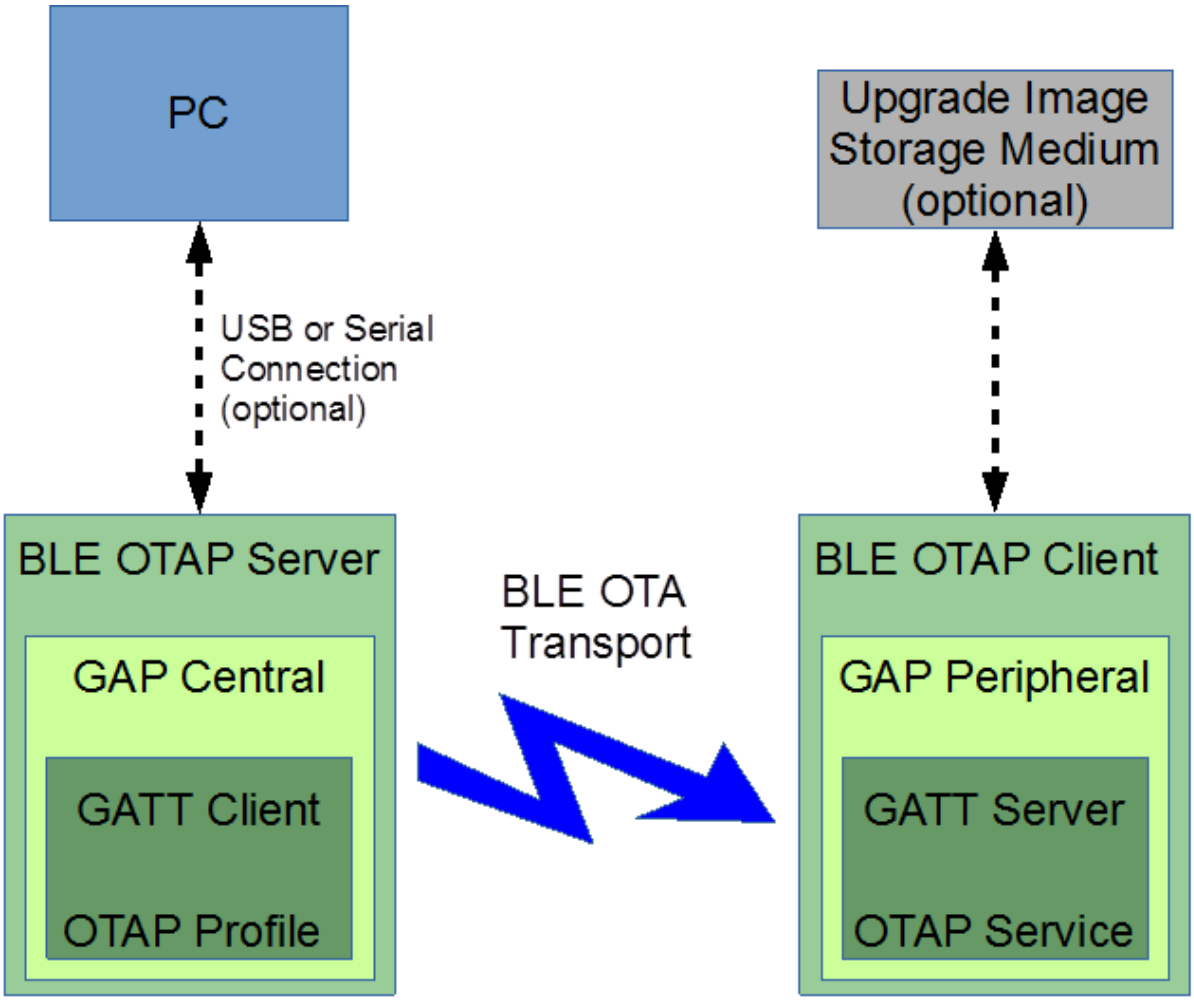
For example, if the low power constraint set from the application is Deep-sleep mode, and no other constraint is set, the**SDK Power Manager** selects Deep-sleep the next time the device enters low power. However, there might be a case when a WFI constraint is set (*PWR_SetLowPowerModeConstraint (PWR_WFI)*) by another component, such as the SecLib module that operates Hardware encryption. In such cases, the **SDK Power Manager** selects this WFI mode until the constraint is released by the SecLib module (*PWR_ReleaseLowPowerModeConstraint(PWR_WFI)*).

If it is required to change the mode from Deep-sleep to Power-down mode, the deep sleep constraint (*PWR_ReleaseLowPowerModeConstraint(PWR_DeepSleep)*) must be released and the power-down constraint (*PWR_SetLowPowerModeConstraints(PWR_PowerDown)*) must be set. The **SDK Power Manager** selects the Power-down mode when the device enters low power.

Parent topic:*Low-Power Management*

Over the Air Programming (OTAP) This chapter contains a detailed description of the Over The Air Programming capabilities of the Bluetooth Low Energy Host Stack enabled by dedicated GATT Service/Profile and of the support modules needed for OTA programming.

The image transfer is done using a dedicated protocol which is designed to run on both the Bluetooth Low Energy transport and serial transport.



The container for the upgrade image is an image file which has a predefined format which is described in detail. The image file format is independent of the protocol but must contain information specific to the image upgrade infrastructure on an OTAP Client device. Detailed information on how to build an image file starting from a generic format executable generated by an embedded cross-compiling toolchain is shown.

The demo applications implement a typical scenario where a new image is sent from a PC via serial interface to a Bluetooth Low Energy OTAP Server and then over the air to an OTAP Client which is the target of the upgrade image. There are 3 applications involved in the OTAP demo: 1 PC application which builds the image file and serves it to the embedded OTAP Server and 2 embedded applications (OTAP Server and OTAP Client). This chapter contains enough information for building Bluetooth Low Energy OTAP applications which implement different image upgrade scenarios specific to other use cases.

General functionality A Bluetooth Low Energy OTAP system consists of an OTAP Server and an OTAP Client which exchange an image file over the air using the infrastructure provided by Bluetooth Low Energy (GAP, GATT, SM) via a custom GATT Service and GATT Profile. Additionally, a third application may be used to serve an image to the embedded OTAP Server.

The OTAP Server runs on the GATT Client via the Bluetooth Low Energy OTAP Profile and the OTAP Client runs on the GATT Server via the Bluetooth Low Energy OTAP Service. For the moment the OTAP Server runs on the GAP Central and the OTAP Client runs on the GAP Peripheral.

The Figure shows a typical image upgrade scenario.

Parent topic:*Over the Air Programming (OTAP)*

Bluetooth Low Energy OTAP service-profile The Bluetooth Low Energy OTAP Service is implemented using the GATT Server which runs on the OTAP Client (GAP Peripheral).

The Bluetooth LE OTAP Service does not require any other Bluetooth LE services because it is a custom service it has a 128-bit UUID. The service has 2 custom characteristics which also have 128-bit UUIDs.

The service must be included in the GATT database of the GATT Server as described in *Creating GATT database* of this document.

OTAP service and characteristics The OTAP Service has a custom 128-bit UUID which is shown below. The UUID is based on a base 128-bit UUID used for Bluetooth LE custom services and characteristics. These are shown in the tables below.

Service	128-bit UUID
Base Bluetooth Low Energy	00000000 -ba5e-f4ee-5ca1-eb1e5e4b1ce0

The OTAP Service custom 128-bit UUID is built using the base UUID by replacing the most significant 4 bytes which are 0 with a value specific to the OTAP Service which is 01FF5550 in hexadecimal format.

Service	UUID (128-bit)
Bluetooth LE OTAP Service	01ff5550 -ba5e-f4ee-5ca1-eb1e5e4b1ce0

The Bluetooth LE OTAP Service Characteristics UUIDs are built the same as the Bluetooth LE OTAP Service UUID starting from the base 128-bit UUID but using other values for the most significant 4 bytes.

Characteristic	UUID (128-bit)	Properties	Descriptors
Bluetooth LE OTAP Control Point	01ff5551 -ba5e-f4ee-5ca1-eb1e5e4b1ce0	Write, Indicate	CCC
Bluetooth LE OTAP Data	01ff5552 -ba5e-f4ee-5ca1-eb1e5e4b1ce0	Write Without Response	-

Both characteristics are implemented as variable length characteristics.

The Bluetooth LE OTAP Control Point Characteristic is used for exchanging OTAP commands between the OTAP Server and the OTAP Client. The OTAP Client sends commands to the OTAP Server using ATT Notifications for this characteristic and the OTAP Server sends commands to the OTAP Client by making ATT Write Requests to this characteristic. Both ATT Writes and ATT Notifications are acknowledged operations via ATT Write Responses and ATT Confirmations.

The Bluetooth LE OTAP Data characteristic is used by the OTAP Server to send parts of the OTAP image file to the OTAP Client when the ATT transfer method is chosen by the application. The ATT Write Commands (GATT Write Without Response operation) is not an acknowledged operation.

The Bluetooth LE OTAP service and characteristics 128-bit UUIDs are defined in the *gatt_uuid128.h* just as shown below.

```
UUID128(uuid_service_otap, 0xE0, 0x1C, 0x4B, 0x5E, 0x1E, 0xEB, 0xA1, 0x5C, 0xEE, 0xF4, 0x5E, 0xBA,␣
↪0x50, 0x55, 0xFF, 0x01)
UUID128(uuid_char_otap_control_point, 0xE0, 0x1C, 0x4B, 0x5E, 0x1E, 0xEB, 0xA1, 0x5C, 0xEE, 0xF4,␣
↪0x5E, 0xBA, 0x51, 0x55, 0xFF, 0x01)
UUID128(uuid_char_otap_data, 0xE0, 0x1C, 0x4B, 0x5E, 0x1E, 0xEB, 0xA1, 0x5C, 0xEE, 0xF4, 0x5E,␣
↪0xBA, 0x52, 0x55, 0xFF, 0x01)
```

The service is included into the GATT database of the device. It is declared in the *gatt_db.h* file as shown below.

```
PRIMARY_SERVICE_UUID128(service_otap, uuid_service_otap)
CHARACTERISTIC_UUID128(char_otap_control_point, uuid_char_otap_control_point,␣
↪(gGattCharPropWrite_c | gGattCharPropIndicate_c))
VALUE_UUID128_VARLEN(value_otap_control_point, uuid_char_otap_control_point,␣
↪(gPermissionFlagWritable_c), 16, 16, 0x00)
CCCD(cccd_otap_control_point)
CHARACTERISTIC_UUID128(char_otap_data, uuid_char_otap_data, (gGattCharPropWriteWithoutRsp_
↪c))
VALUE_UUID128_VARLEN(value_otap_data, uuid_char_otap_data, (gPermissionFlagWritable_c),␣
↪gAttMaxMtu_c - 3, gAttMaxMtu_c - 3, 0x00)
```

The Bluetooth LE OTAP Control Point characteristic should be large enough for the longest command which can be exchanged between the OTAP Server and The OTAP Client.

The Bluetooth LE OTAP Data characteristic should be large enough for the longest data chunk command the OTAP Client expects from the OTAP Server to be sent via ATT. The maximum length

of the OTAP Data Characteristic value is ATT_MTU- 3. 1 byte is used for the ATT OpCode and 2 bytes are used for the Attribute Handle when performing a Write Without Response, the only operation permitted for this characteristic value.

Parent topic: Bluetooth Low Energy OTAP service-profile

OTAP server and OTAP client interactions The OTAP Server application scans for devices advertising the OTAP Service. When it finds one it connects to that device and notifies it of the available image files or waits for requests regarding available image files. The behavior is specific to each application which needs the OTAP functionality. The Bluetooth LE OTAP Protocol described below details how to do this.

After an OTAP Server (GAP Central, GATT Client) connects to an OTAP Client (GAP Peripheral, GATT Server) it scans the device database and identifies the handles of the OTAP Control Point and OTAP Data characteristics and their descriptors. Then it writes the CCC Descriptor of the OTAP Control point to allow the OTAP Client to send it commands via ATT Indications. It can send commands to the OTAP Client by using ATT Write Commands to the OTAP Control Point characteristic.

After the connection is established, if the OTAP Client wants to use the L2CAP CoC transfer method it must register a L2CAP PSM with the OTAP Server.

The OTAP Client only starts any image information request or image transfer request procedures only after the OTAP Server writes the OTAP Control Point CCCD to ensure there is bidirectional communication between the devices.

Parent topic: Bluetooth Low Energy OTAP service-profile

Parent topic:*Over the Air Programming (OTAP)*

Bluetooth LE OTAP protocol The protocol consists of a set of commands (messages) which allow the OTAP Client to request or be notified about the available images on an OTAP Server and to request the transfer of parts of images from the OTAP Server.

All commands with the exception of the image data transfer commands are exchanged through the OTAP Control Point characteristic of the OTAP Service. The data transfer commands are sent only from the OTAP Server to the OTAP Client either via the OTAP Data characteristic of the OTAP Service or via a dedicated Credit Based Channel assigned to a L2CAP PSM.

Protocol design considerations The OTAP Client is a GAP Peripheral device, and therefore has limited resources. This is why the OTAP Protocol was designed in such a way that it is at the discretion of the OTAP Client if, when, how fast and how much of an available upgrade image is transferred from the OTAP Server. The OTAP Client also decides which is the image transfer method based on its capabilities. Two image transfer methods are supported at this moment: the ATT Transfer Method and the L2CAP PSM CoC Transfer Method.

The ATT Transfer Method is supported by all devices which support Bluetooth LE but it has the disadvantage of a small data payload size and a larger Bluetooth LE stack protocols overhead leading to a lower throughput. This disadvantage has been somewhat reduced by the introduction of the Long Frames feature in the Bluetooth LE specification 4.2 Link Layer which allows for a larger ATT_MTU value. The L2CAP PSM CoC Transfer Method is an optional feature available for devices running a Bluetooth stack version 4.1 and later. The protocol overhead is smaller and the data payload is higher leading to a high throughput. The L2CAP PSM Transfer Method is the preferred transfer method and it is available on all Bluetooth LE Devices if the application requires it.

Based on application requirements and device resources and capabilities the OTAP Clients can request blocks of OTAP images divided into chunks. To minimize the protocol overhead and maximize throughput an OTAP Client makes a data block request specifying the block size and the chunk size and the OTAP Server sends the requested data chunks (which have a sequence

number) without waiting for confirmation. The block size, chunk size and number of chunks per block are limited and suitable values must be used based on application needs.

The OTAP Client can stop or restart an image block transfer at any time if the application requires it or a transfer error occurs. The OTAP Server implementation can be almost completely stateless. The OTAP Server does not need to remember what parts of an image have been transferred, this is the job of the OTAP Client which can request any part of an image at any time. This allows it to download parts of the image whenever and how fast its resources allow it. The OTAP Server simply sends image information and image parts on request.

The Bluetooth LE OTAP Protocol is designed to be used not only on Bluetooth LE transport medium but on any transport medium, for example a serial communication interface or another type of wireless interface. This may be useful when transferring an upgrade image from a PC or a mobile device to the OTAP Server to be sent via Bluetooth LE to the OTAP Clients which require it. In the OTAP Demo Applications the embedded OTAP Server relays OTAP commands between an OTAP Client and a PC via a serial interface and using a FSCI type protocol. Effectively the OTAP Client downloads the upgrade image from the PC and not from the OTAP Server. Other transfer methods may be used based on application needs.

Parent topic: Bluetooth LE OTAP protocol

Bluetooth Low Energy OTAP commands The Bluetooth LE OTAP Commands general format is shown below. A command consists of two parts, a Command ID, and a Command Payload as shown in the table below.

Field Name	CmdId	CmdPayload
Size (Bytes)	1	variable

Commands are sent over the transport medium starting with the Command ID and continuing with the Command Payload.

All multibyte command parameters in the Command Payload are sent in a least significant octet first order (little endian).

A summary of the commands supported by the Bluetooth LE OTAP Protocol is shown in the table below. Each of the commands is then detailed in its own section.

CmdId	Command Name
0x01	New Image Notification
0x02	New Image Info Request
0x03	New Image Info Response
0x04	Image Block Request
0x05	Image Chunk
0x06	Image Transfer Complete
0x07	Error Notification
0x08	Stop Image Transfer

New image notification command This command can be sent by an OTAP Server to an OTAP Client, usually immediately after the first connection, to notify the OTAP Client of the available images on the OTAP Server.

CmdId	Name	Dir	Parameters	Param Size (Bytes)	Description	Total Size (CmdId+Payload)
0x03	New Image Info Response	S->C	ImageId	2	Image Id. Value 0xFFFF is reserved as “no image available”	15
0x03	New Image Info Response	S->C	ImageVersion	8	Image file version.	15
0x03	New Image Info Response	S->C	ImageFileSize	4	Image file size.	15

The *ImageId* parameter should not be ‘0x0000’, which is the reserved value for the current running image or 0xFFFF, which is the reserved value for “no image available”.

Parent topic: Bluetooth Low Energy OTAP commands

New image info request command This command can be sent by an OTAP Client to an OTAP Server to inquire about available upgrade images on the OTAP Server.

CmdId	Name	Dir	Parameters	Param Size (Bytes	Description	Total Size (CmdId+Payload)
0x02	New Image Info Request	C->S	CurrImageId	2	Id of the currently running image. Should be 0x0000.	11
0x02	New Image Info Request	C->S	CurrImageV	8	Version of the currently running image. A value of all zeroes signals that the client is looking for all images available on an OTAP Server. A value of all zeroes requests information about all images on the server.	11

- The *CurrImageId* parameter should be set to 0x0000 to signify the current running image.
- The *CurrImageVer* parameter should contain sufficient information about the target device for the OTAP Server to determine if it has an upgrade image available for the requesting OTAP Client.
- A value of all zeroes for the *CurrImageVer* means that an OTAP Client is requesting information about all available images on an OTAP Server and the OTAP Server should send a New Image Info Response for each image.

Parent topic: Bluetooth Low Energy OTAP commands

New image info response command This command is sent by the OTAP Server to the OTAP Client as a response to a New Image Information Request Command.

CmdId	Name	Dir	Parameters	Param Size (Bytes)	Description	Total Size (CmdId+Payload)
0x03	New Image Info Response	S->C	ImageId	2	Image Id. Value 0xFFFF is reserved as “no image available”	15
0x03	New Image Info Response	S->C	ImageVersion	8	Image file version	15
0x03	New Image Info Response	S->C	4 Image file size.	4	Image file size	15

The *ImageId* parameter with a value of 0xFFFF is reserved for the situation where no upgrade image is available for the requesting device.

Parent topic: Bluetooth Low Energy OTAP commands

Image block request command This command is sent by the OTAP Client to the OTAP Server to request a part of the upgrade image after it has determined the OTAP Server has an upgrade image available.

When an OTAP Server Receives this command it should stop any image file chunk transfer sequences in progress.

CmdId	Nam	Dir	Parameters	Para Size	Description	Total Size (CmdId+Payload)
0x04	Image Block Reques	C->S	StartPositionBlockSizeChunkSizeTransferMethodL2ca	4421	Start position of the image block to be transferred.Requested total block size in bytes.Should be optimized to the Transfer Channel type. The maximum number of chunks per block is 256. Value is inbytes.0x00 - ATT 0x01 – L2CAP PSM Credit based channel0x0004 - ATT Other values – PSM for credit based channels	16

The *ImageId* parameter contains the ID of the upgrade image.

The *StartPosition* parameter specifies the location in the image upgrade file at which the requested block starts.

The *BlockSize* and *ChunkSize* parameters specify the size in bytes of the block to be transferred and the size of the chunks into which a block is separated. The *ChunkSize* value must be chosen in such a way that the total number of chunks can be represented by the *SeqNumber* parameter of the Image Chunk Command. At the moment this parameter is 1 byte in size so there are a maximum of 256 chunks per block. The chunk sequence number goes from 0 to 255 (0x00 to 0xFF). If this condition is not met or the requested block is not entirely into the image file bounds an error is sent to the OTAP Client when the OTAP Server receives this misconfigured Image Block Request Command.

The maximum value of the *ChunkSize* parameter depends on the maximum ATT_MTU and L2CAP_MTU supported by the Bluetooth LE stack version and implementation.

The *TransferMethod* parameter is used to select the transfer method which can be ATT or L2CAP PSM CoC. The *L2capChannelOrPsm* parameter must contain the value 0x0004 for the ATT transfer

method and another value representing the chosen PSM for the L2CAP PSM transfer method. The default PSM for the Bluetooth LE OTAP demo applications is 0x004F for both the OTAP Server and the OTAP Client although the specification allows different values at the 2 ends of the L2CAP PSM connection. The PSM must be in the range reserved by the Bluetooth specification which is 0x0040 to 0x007F.

The optimal value of the *ChunkSize* parameter depends on the chosen transfer method and the Link Layer payload size. Ideally it must be chosen in such a way that full packets are sent for every chunk in the block.

The default Link Layer payload is 27 bytes form which we subtract 4 for the L2CAP layer and 3 for the ATT layer (1 for the ATT Cmd Opcode and 2 for the Handle) leaving us with a 20 byte OTAP protocol payload. From these 20 bytes we subtract 1 for the OTAP CmdId and 1 for the chunk sequence number leaving us with an optimum chunk size of 18 for the ATT transfer method – which is the default in the demo applications. For the L2CAP PSM transfer method the chosen default chunk size is 111. This was chosen so as a chunk fits exactly 5 link layer packets. The default L2CAP payload of 23 (27 - 4) multiplied by 5 gives us 115 from which we subtract 2 bytes for the SDU Length (which is only sent in the first packet), 1 byte for the OTAP CmdId and 1 byte for the chunk sequence number which leaves exactly 111 bytes for the actual payload.

If the Link layer supports Long Frames feature then the chunk size should be set according to the negotiated ATT MTU for the ATT transfer method. From the negotiated ATT MTU (*att_mtu*) subtract 3 bytes for the ATT layer (1 for the ATT Cmd Opcode and 2 for the Handle) then subtract 2 bytes for the OTAP protocol (1 for the CmdId and 1 for the chunk sequence number) to determine the optimum chunk size (*optimum_att_chunk_size = att_mtu – 3 – 2)*. For the L2CAP PSM transfer method the chunk size can be set based on the maximum L2CAP SDU size (*max_l2cap_sdu_size*) from which 4 bytes should be subtracted, 2 for the SDU Length and 2 for the OTAP protocol (*optimum_l2cap_chunk_size = max_l2cap_sdu_size – 3 – 2*). In some particular cases reducing the L2CAP chunk size could lead to better performance. If the L2CAP chunk size needs to be reduced it should be reduced so it fits exactly a number of link layer packets. An example of how to compute an optimal reduced L2CAP chunk size is given in the previous paragraph.

Parent topic: Bluetooth Low Energy OTAP commands

Image chunk command One or more Image Chunk Commands are sent from the OTAP Server to the OTAP Client after an Image Block Request is received by the former. The image chunks are sent via the ATT Write Without Response mechanism if the ATT transfer method is chosen and directly via L2CAP if the L2CAP PSM CoC transfer method is chosen.

Cm-dId	Name	Dir	Pa-ram-eters	Para Size	Description	Total Size (Cm-dId+Payload)
0x05	Im-age Chunl	S-->C	Se-qNum-ber-Data	1vari able	In the range 0 -> BlockSize/ChunkSize - calculated by Server, checked by Client. The command code is present even when ATT is used.Actual data	3 or more

The *SeqNumber* parameter is the chunk sequence number and it has incremental values from 0 to 255 (0x00 to 0x FF) for a maximum of 256 chunks per block.

The *Data* parameter is an array containing the actual image part being transferred starting from the *BlockStartPosition + SeqNumber ChunkSize* position in the image file and containing *Chunk-Size* or less bytes depending on the position in the block. Only the last chunk in a block can have less than *ChunkSize*bytes in the Image Chunk Command data payload.

Parent topic: Bluetooth Low Energy OTAP commands

Image transfer complete command This command is sent by the OTAP Client to the OTAP Server when an image file has been completely transferred and its integrity has been checked.

CmdId	Name	Dir	Parameters	Param Size	Description	Total Size (CmdId+Payload)
0x06	Image Transfer Complete	C->S	ImageIdStatus	21	Image IdStatus of the image transfer. 0x00 - Success	4

The *ImageId* parameter contains the ID of the image file that was transferred.

The *Status* parameter is 0x00 (Success) if image integrity and possibly other checks have been successfully made after the image is transferred and another value if integrity or other kind of errors have occurred.

If the status is 0x00 the OTAP Client can trigger the Bootloader to start flashing the new image. The image flashing should take about 15 seconds for a 160 KB flash memory.

Parent topic: Bluetooth Low Energy OTAP commands

Error notification command This command can be sent by both the OTAP Server and the OTAP Client when an error of any kind occurs. When an OTAP Server receives this command, it should stop any image file chunk transfer sequences in progress.

CmdId	Name	Dir	Parameters	Param Size (Bytes	Description	Total Size (CmdId+Payload)
0x07	Error Notification	Bidi	CmdIdErrorStatus	11	Id of the command which generated the error.Error Status: Examples: out of image bounds, chunk too small, chunk too large, image verification failure, bad command format, image not available, unknown command	3

The *CmdId* parameter contains the ID of the command which caused the error (if applicable).

The *ErrorStatus* parameter contains the source of the error. All error statuses are defined in the *otapStatus_t* enumerated type in the *otap_interface.h* file.

Parent topic: Bluetooth Low Energy OTAP commands

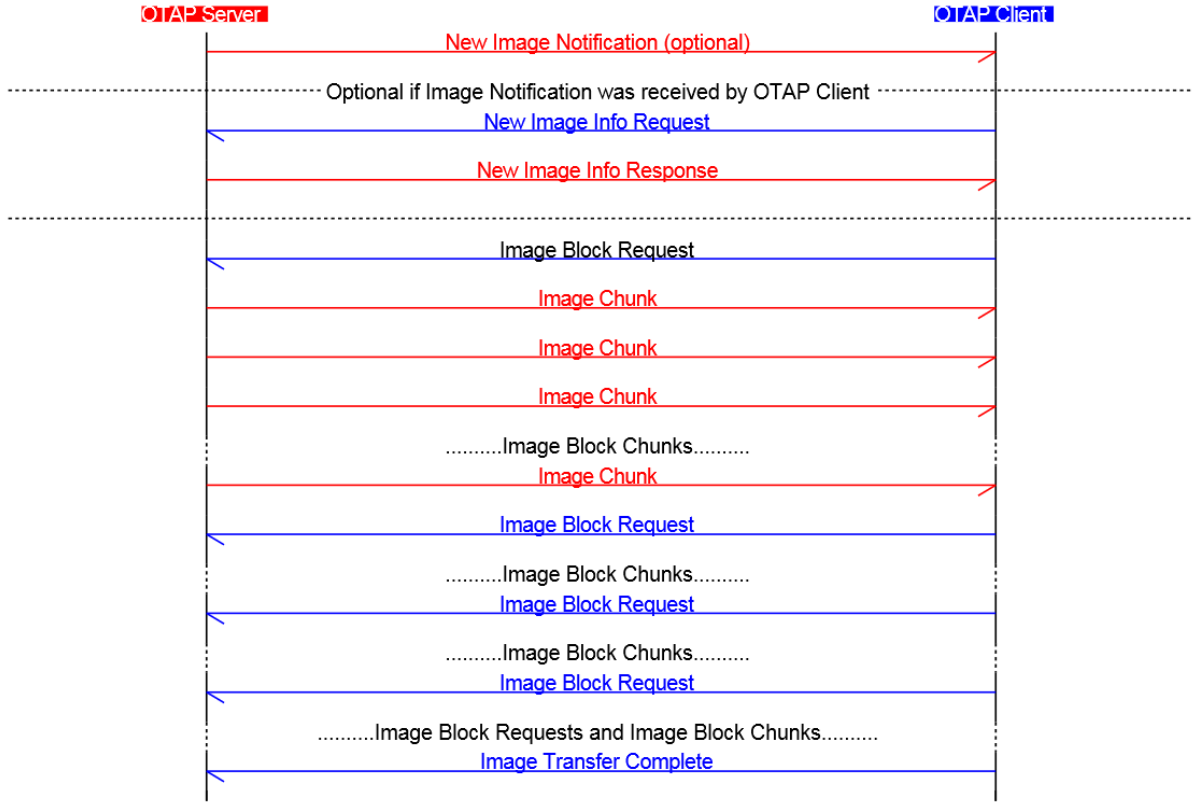
Stop image transfer command This command is sent from the OTAP Client to the OTAP Server whenever the former wants to stop the transfer of an image block which is currently in progress, or from OTAP Server to the OTAP Client when the image transfer is stopped from application (Test Tool).

CmdId	Name	Dir	Parameters	Param Size	Description	Total Size (CmdId+Payload)
0x08	Stop Image Transfer	C->S	ImageId	2	Image Id	3

The *ImageId* parameter contains the ID of the image being transferred.

Parent topic: Bluetooth Low Energy OTAP commands

Parent topic: Bluetooth LE OTAP protocol



OTAP client–server interactions The interactions between the OTAP Server and OTAP Client start immediately after the connection, discovery of the OTAP Service characteristics and writing of the OTAP Control Point CCC Descriptor by the OTAP Server.

The first command sent could be a New Image Notification sent by the OTAP Server to the OTAP Client or a New Image Info Request sent by the OTAP Client. The OTAP Server can respond with a New Image Info response if it has a new image for the device which sent the request (this can be determined from the *ImageVerison* parameter). The best strategy depends on application requirements.

After the OTAP Client has determined that the OTAP Sever has a newer image it can start downloading the image. This is done by Sending Image Block Request commands to retrieve parts of the image file. The OATP Server answers to these requests with one or more Image Chunk Commands via the requested transfer method or with an Error Notification if there are improper parameters in the Image Block Request. The OTAP Client makes as many Image Block Requests as it is necessary to transfer the entire image file.

The OTAP Client decides how often Image Block Request Commands are sent and can even stop a block transfer which is in progress via the Stop Image Transfer Command. The OTAP Client is in complete control of the image download process and can stop it and restart it at any time based on its resources and application requirements.

A typical **Bluetooth LE OTAP Image Transfer** scenario is shown in the message sequence chart Figure.

Parent topic:*Over the Air Programming (OTAP)*

Bluetooth Low Energy OTAP image file format The Bluetooth LE OTAP Image file has a binary file format. It is composed of a header followed by a number of sub-elements. The header describes general information about the file. There are some predefined sub-elements of a file but an end manufacturer could add manufacturer-specific sub-elements. The header does not have details of the sub-elements. Each element is described by its type.

The general format of an image file is shown in the table below.

Image File Element	Value Field Length (bytes)	Description
Header	Variable	The header contains general information about the image file.
Upgrade Image Sub-element	Variable	This sub-element contains the actual binary executable image, which is copied into the flash memory of the target device. The maximum size of this sub-element depends on the target hardware.
Image File CRC Sub-element	2	This is a 16-bit CCITT type CRC which is calculated over all elements of the image file with the exception of the Image File CRC sub-element itself. This must be the last sub-element in an image file.

Each sub-element in a Bluetooth LE OTAP Image File has a Type-Length-Value (TLV) format. The type identifier provides forward and backward compatibility as new sub-elements are introduced. Existing devices that do not understand newer sub-elements may ignore the data.

The following table shows the general format of a Bluetooth LE Image File sub-element.

Sub-field	Size (Bytes)	Format	Description
Type	2	uint16	Type Identifier – determines the format of the data contained in the value field
Length	4	uint32	Length of the *Value* field of the sub-element.
Value	variable	uint8[]	Data payload

Some sub-element type identifiers are reserved while others are left for manufacturer-specific use. The table below shows the reserved type identifiers and the manufacturer-specific ranges.

Type Identifiers	Description
0x0000	Upgrade Image
0x0001 – 0xefff	Reserved
0xf000 – 0xffff	Manufacturer-Specific Use

The OTAP Demo applications use two of the manufacturer-specific sub-element type identifiers while the rest remain free to use. The two are shown in the table below along with a short description.

Manufacturer-specific Type Identifiers	Sub-element Name	Notes
0xf000	Sector Bitmap	Bitmap that signals the bootloader the sectors of the internal flash, which should be overwritten and which should remain as is.
0xf100	Image File CRC	16-bit CRC that is computed over the image file with the exception of the CRC sub-element itself.

Bluetooth Low Energy OTAP header The format and fields of the Bluetooth Low Energy OTAP Header are summarized in the table below.

Octets	Data Types	Field Name	Mandatory/Optional
4	Unsigned 32-bit integer	Upgrade File Identifier	M
2	Unsigned 16-bit integer	Header Version	M
2	Unsigned 16-bit integer	Header Length	M
2	Unsigned 16-bit integer	Header Field Control	M
2	Unsigned 16-bit integer	Company Identifier	M
2	Unsigned 16-bit integer	Image ID	M
8	8 byte array	Image Version	M
32	Character string	Header String	M
4	Unsigned 32-bit integer	Total Image File Size	M

The fields are shown in the order they are placed in memory from the first location to the last.

The total size of the header without the optional fields (if defined by the *Header Field Control*) is 58 bytes.

All the fields in the header have a little endian format with the exception of the *Header String* field which is an ASCII character string.

A packed structure type definition for the contents of the Bluetooth LE OTAP Header can be found in the *otap_interface.h* file.

Upgrade file identifier Fixed value 4 byte field used to identify the file as being a Bluetooth LE OTAP Image File. The predefined value is "**0x0B1EF11E**".

Parent topic: Bluetooth Low Energy OTAP header

Header version This 2 byte field contains the major and minor version number. The high byte contains the major version and the low byte contains the minor version. The current value is "**0x0100**" with the major version "**01**" and the minor version **"00**". A change to the minor version means the OTA upgrade file format is still backward compatible, while a change to the major version suggests incompatibility.

Parent topic: Bluetooth Low Energy OTAP header

Header length Length of all the fields in the header including the ***Upgrade File Identifier*** field, ***Header Length*** field and all the optional fields. The value insulates existing software against new fields that may be added to the header. If new header fields added are not compatible with current running software, the implementations should process all fields they understand and then skip over any remaining bytes in the header to process the image or CRC sub-element. The value of the ***Header Length*** field depends on the value of the Header Field Control field, which dictates which optional header fields are included.

Parent topic: Bluetooth Low Energy OTAP header

Header field control This is a 2-byte bit mask that specifies the optional fields present in the OTAP Header.

In case no optional fields are defined, this whole field is reserved and should be set to "**0x0000**".

Parent topic: Bluetooth Low Energy OTAP header

Company identifier This is the company identifier assigned by the Bluetooth SIG. The Company Identifier used for the OTAP demo applications is "**0x01FF**".

Parent topic: Bluetooth Low Energy OTAP header

Image ID This is a unique short identifier for the image file. It is used to request parts of an image file. This number should be unique for all images available on a Bluetooth LE OTAP Server.

- The value 0x0000 is reserved for the current running image.
- The value 0xFFFF is reserved as a "no image available" code for New Image Info Response commands.

This field value must be used in the *ImageID* field in the *New Image Notification* and *New Image Info Response* commands.

Parent topic: Bluetooth Low Energy OTAP header

Image version This is the full identifier of the image file. It should allow a Bluetooth LE OTAP Client to identify the target hardware, stack version, image file build version, and other parameters if necessary. The recommended format of this field (which is used by the OTAP Demo applications) is shown below but an end device manufacturer could choose different format. The subfields are shown in the order they are placed in memory from the first location to the last. Each subfield has a little-endian format, if applicable.

Subfield	Size (bytes)	Format	Description
Build Version	3	uint8[]	Image build version.
Stack Version	1	uint8	0x41 for example for Bluetooth Low Energy Stack version 4.1.
Hardware ID	3	uint8[]	Unique hardware identifier.
End Manufacturer Id	1	uint8	ID of the hardware–specific to the end manufacturer

This field value must be used in the *ImageVersion* field in the New Image Notification and New Image Info Response commands.

Parent topic: Bluetooth Low Energy OTAP header

Header string This is a manufacturer-specific string that may be used to store other necessary information as seen fit by each manufacturer. The idea is to have a human readable string that can prove helpful during the development cycle. The string is defined to occupy 32 bytes of space in the OTAP Header. The default string used for the Bluetooth LE OTAP demo application is "BLE OTAP Demo Image File".

Parent topic: Bluetooth Low Energy OTAP header

Total image file size The value represents the total image size in bytes. This is the total of data in bytes that is transferred over-the-air from the server to the client. In most cases, the total image size of an OTAP upgrade image file is the sum of the sizes of the OTAP Header and all the other sub-elements on the file. If the image contains any integrity and/or source identity verification fields then the Total Image File Size also includes the sizes of these fields.

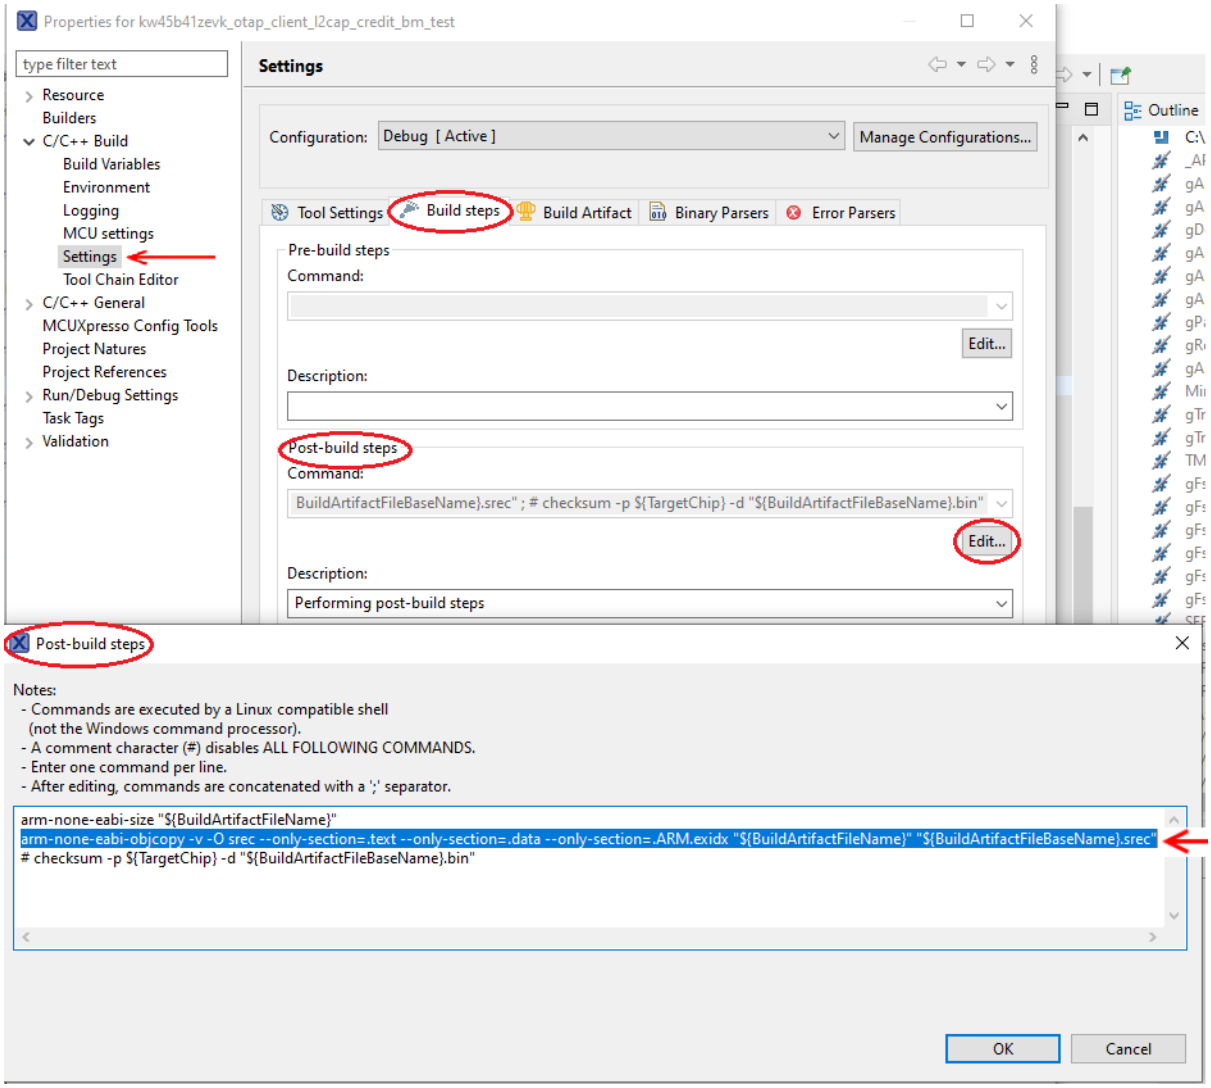
Building Bluetooth Low Energy OTAP image file from SREC file A SREC (Motorola S-record) file is an ASCII format file which contains binary information. Common file extensions are: .srec, .s19, .s28, .s37 and others. Most modern compiler toolchains can generate an SREC format executable.



The steps described in this section enable the creation of a SREC file for your embedded application in IAR Embedded Workbench.

For this, open the target properties and go to the **Output Converter** tab. Activate the **Generate additional output** checkbox and choose the **Motorola** option from the **Output format** drop down menu. From the same pane you can also override the name of the output file. A screenshot of the described configuration is shown in Figure.

In MCUXpresso IDE, go to **Project properties** -> **Settings** -> **Build steps** window and press the "**Edit**" button for the Post-build steps. A Post-build steps window shows up in which the following command must be added:

```
arm-none-eabi-objcopy -v -O srec --only-section=.text --only-section=.data --only-section=.ARM.exidx
"${BuildArtifactFileName}"
"${BuildArtifactFileBaseName}.srec"
```

A snapshot of this window is shown in the Figure below.

The format of the SREC file is shown in table below. It contains lines of text called records which have a specific format. An example of the contents of a SREC file is shown below.

```
S02000006F7461705F636C69656E745F6174745F4672656552544F532E73726563A1

```

All records start with the ASCII letter 'S' followed by an ASCII digit from '0' to '9'. These two characters from the record type identify the format of the data field of the record.

The next 2 ASCII characters are 2 hex digits that indicate the number of bytes (hex digit pairs) which follow the rest of the record (address, data, and checksum).

The address that follows next can have 4, 6, or 8 ASCII hex digits, depending on the record type.

The data field is placed after the address and it contains 2 * n ASCII hex digits for 'n' bytes of actual data.

The last element of the S record is the checksum, which comprises 2 ASCII hex digits. The checksum is computed by adding all the bytes of the byte count, address, and data fields. Then the ones complement of the least significant octet of the sum is computed to determine the checksum.

Field	Record Type	Count	Address	Data	Checksum	Line Terminator
Format	"Sn", n=0..9	ASCIIhex digits	ASCIIhex digits	ASCIIhex digits	ASCIIhex digits	"\r\n"
Length (characters)	2	2	4,6,8	*Count –*len*(Address) – *len(*Checksum)*	2	2

More details about the SREC file format can be found at this location: en.wikipedia.org/wiki/SREC_(file_format).

We are only interested in records that contain actual data. These are S1, S2, and S3 records. The other types of records can be ignored.

The S1, S2, and S3 records are used to build the Upgrade Image Sub-element of the image file simply by placing the record data at the location specified by the record address in the *Value* field of the Sub-element. It is recommended to fill all gaps in S record addresses with 0xFF.

To build an OTAP Image File from a SREC file, follow the procedure described below:

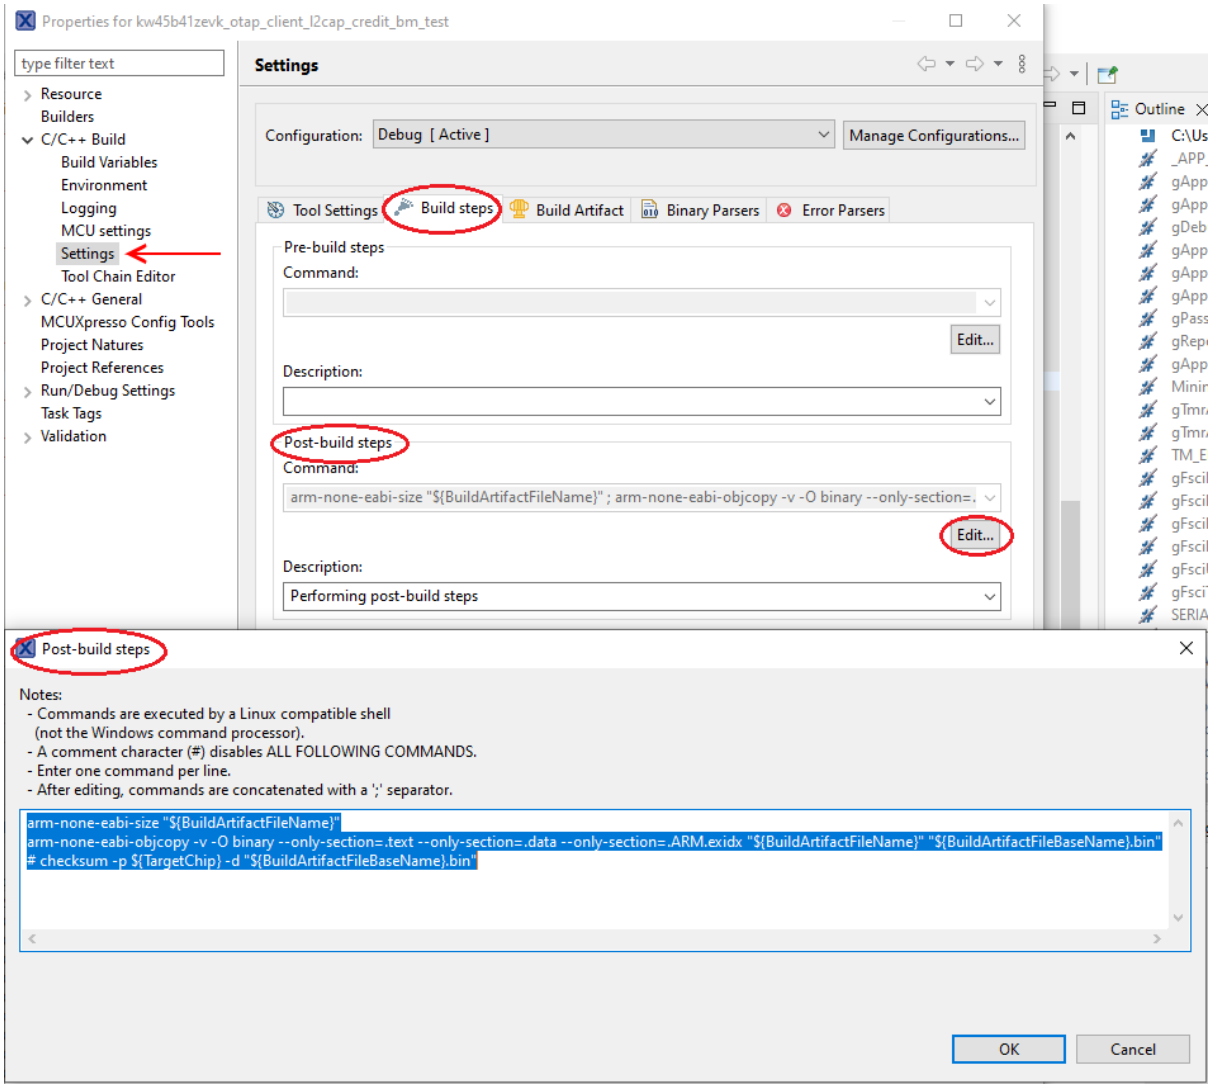
- Generate the SREC file by correctly configuring your toolchain to do so.
- Create the image file header.
  - Set the Image ID field of the header to be unique on the OTAP Server.
  - Leave the Total Image File Size Field blank for the moment.
- Create the Upgrade Image Sub-element
  - Read the S1, S2, and S3 records from the SREC file and place the binary record data to the record addresses in the *Value* filed of the sub-element. Fill all address gaps in the S records with 0xFF.

  - Fill in the *Length* field of the sub-element with the length of the written *Value* field.
- Create the Sector Bitmap Sub-element
  - A default working setting would be all byes 0xFF for the *Value* field of this sub-element.
- Create the Image File CRC Sub-element
  - Compute the total image file size as the length of the header + the length of all 3 sub-elements and fill in the appropriate filed in the header with this value.
  - Compute and write the *Value*field of this sub-element using the header and all sub-elements except this one.
  - The *OTA_CrcCompute()* function in the *OtaSupport.c* file can be used to incrementally compute the CRC.

If the Image ID is not available when the image file is created, then the CRC cannot be computed. It can be computed later after the Image ID is established and written in the appropriate field in the header.

Parent topic:*Over the Air Programming (OTAP)*

Building Bluetooth Low Energy OTAP image file from BIN file A BIN file is an binary file which contains an executable image. The most common extension for this type of file is .bin. Most modern compiler toolchains can output a BIN format executable.



To enable the creation of a BIN file for your embedded application in IAR Embedded Workbench open the target properties and go to the *Output Converter* tab. Activate the *"Generate additional output"* checkbox and choose the *binary* option from the *"Output format"* drop down menu. From the same pane you can also override the name of the output file. The Figure shows a screenshot of the described configuration.

In MCUXpresso IDE, go to **Project properties** -> **Settings** -> **Build steps** window and press the "**Edit**" button for the Post-build steps. A Post-build steps window shows up in which the following command must be added:

```
arm-none-eabi-objcopy -v -O binary --only-section=.text --only-section=.data --only-section=.ARM.exidx
  "${BuildArtifactFileName}"
  "${BuildArtifactFileBaseName}.bin"
```

The Figure below shows the Build steps and Post-build steps in **Settings** window.

The format of the BIN file is very simple. It contains the executable image in binary format as is, starting from address 0 and up to the highest address. This type of file does not have any explicit address information.

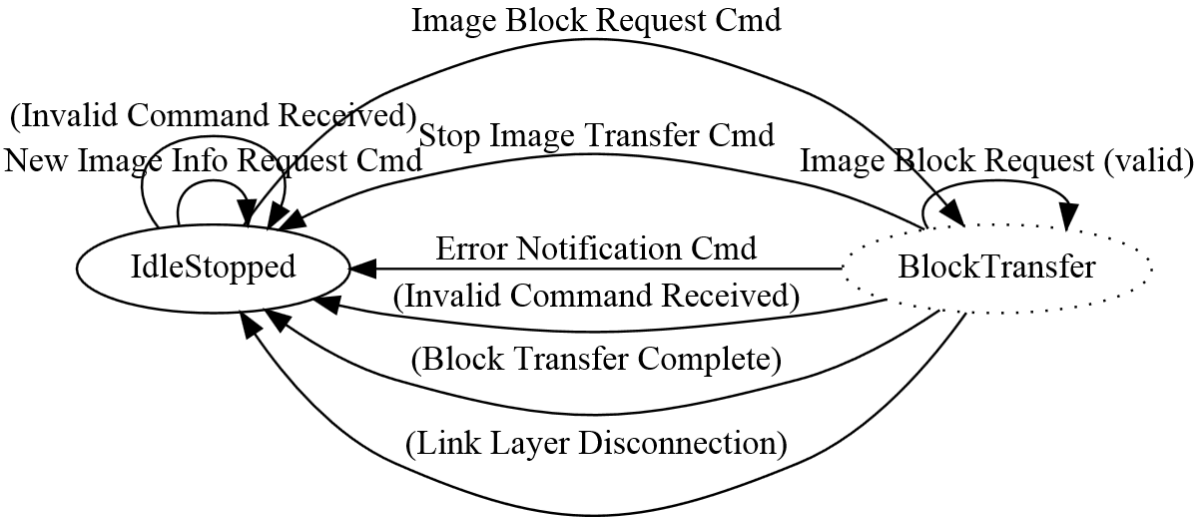
To build an OTAP Image File from a BIN file, follow the procedure below:

- Generate the BIN file by correctly configuring your toolchain to do so.
- Create the image file header
  - Set the Image ID field of the header to be unique on the OTAP Server.
  - Leave the Total Image File Size field blank for the moment.
- Create the Upgrade Image Sub-element
  - Copy the entire contents of the BIN file as is into the *Value* filed of the sub-element.
  - Fill in the *Length* field of the sub-element with the length of the written *Value* filed.
- Create the Sector Bitmap Sub-element
  - A default working setting would be all bytes 0xFF for the *Value* field of this sub-element.
- Create the Image File CRC Sub-element
  - Compute the total image file size as the length of the header + the length of all 3 sub-elements and fill in the appropriate filed in the header with this value.

- Compute and write the *Value*field of this sub-element using the header and all sub-elements except this one.
- The *OTA_CrcCompute()* function in the *OtaSupport.c* file can be used to incrementally compute the CRC.

If the Image ID is not available when the image file is created, then the CRC cannot be computed. It can be computed later after the Image ID is established and written in the appropriate field in the header.

Parent topic:*Over the Air Programming (OTAP)*



Bluetooth Low Energy OTAP application integration The Bluetooth Low Energy OTAP demo applications are standalone applications that only run the OTAP Server and the OTAP Client. In practice, however the OTAP Server and OTAP Client are used alongside with other functions. The OTAP functionality is used as a tool along with the main application on a device.

This section contains some guidelines on how to integrate OTAP functionality into other Bluetooth Low Energy applications.

OTAP server Before any OTAP transactions can be done the application which acts as an OTAP Server must connect to a peer device and perform ATT service and characteristic discovery. Once the handles of the OTAP Service, OTAP Control Point and OTAP Data characteristics and their descriptors are found then OTAP communication can begin.

A good starting point for OTAP transactions for both the OTAP Server and The OTAP client is the moment the Server writes the OTAP Control Point CCCD to receive ATT Indications from the OTAP Client. At that point the Server can send a New Image Notification to the Client if it finds out what kind of device the client is through other means than the OTAP server. How this can be done is entirely application-specific. If the OTAP Server does not know exactly what kind of device is the OTAP Client it can wait for the Client to send a New Image Info Request. Again, the best behavior depends on application requirements.

Once OTAP communication begins then the OTAP Server just has to wait for commands from the OTAP Client and answer them. This behavior is almost completely stateless. An example state diagram for the OTAP Server application is shown in Figure.

The OTAP Server waits in an idle state until a valid Image Block Request command is received and then moves to a pseudo-state and starts sending the requested block. The transfer can be interrupted by some commands (Error Notification, Stop Image Transfer, and so on) or other events (disconnection, user interruption, and so on).

The *otap_interface.h* file contains infrastructure for sending and receiving OTAP Commands and parsing OTAP image files. Packed structure types are defined for all OTAP commands and type enumerations are defined for command parameter values and some configuration values like the data payloads for the different transfer methods.

To receive ATT Indications and ATT Write Confirmations from the OTAP Client the OTAP Server application registers a set of callbacks in the stack. This is done in the *BluetoothLEHost_Initialized* function.

```
App_RegisterGattClientProcedureCallback (BleApp_GattClientCallback);
App_RegisterGattClientIndicationCallback (BleApp_GattIndicationCallback);
```

This *BleApp_GattIndicationCallback()* function is called when any attribute is indicated so the handle of the indicated attribute must be checked against a list of expected handles. In our case, we are looking for the OTAP Control Point handle that was obtained during the discovery procedure.

The *BleApp_GattIndicationCallback()* function from the demo calls an application-specific function called *BleApp_AttributeIndicated()* in which the OTAP Commands are handled.

```
static void BleApp_AttributeIndicated
(
    deviceId_t     deviceId,
    uint16_t       handle,
    uint8_t*       pValue,
    uint16_t       length
)
{
    if (handle == mPeerInformation.customInfo.otapServerConfig.hControlPoint)
    {
       otapCommandVars.pValueTemp = pValue;
        otapCommand_t*  pOtaCmd = otapCommandVars.otapCommandTemp;
        /* ... Missing code here ... */
        /* If the OTAP Server does not have internal storage then all commands must be forwarded
          *  via the serial interface. */
           FsciBleOtap_SendPkt (&(pOtaCmd->cmdId),
                       (uint8_t*)(&(pOtaCmd->cmd)),
                       length - gOtap_CmdIdFieldSize_c);
    }
    elseif (handle == otherHandle)
    {
        /* Handle other attribute indications here */
        /* ... Missing code here ... */
    }
    else
    {
        /*! A GATT Client is trying to GATT Indicate an unknown attribute value.
         * This should not happen. Disconnect the link. */
        Gap_Disconnect (deviceId);
    }
}
```

OTAP Server demo does not have internal storage, so all commands are forwarded via the serial interface.

To send OTAP Commands to the OTAP Client the application running the OTAP Server calls the *OtapServer_SendCommandToOtapClient()* function, which performs an ATT Write operation on the OTAP Control Point attribute.

```
static void OtapServer_SendCommandToOtapClient
        (deviceId_t  otapClientDevId,
         void*       pCommand,
         uint16_t    cmdLength)
```

(continues on next page)

(continued from previous page)

```
{
    /* GATT Characteristic to be written - OTAP Client Control Point */
    gattCharacteristic_t    otapCtrlPointChar;
    bleResult_t             bleResult;

    /* Only the value handle element of this structure is relevant for this operation. */
    otapCtrlPointChar.value.handle = mPeerInformation.customInfo.otapServerConfig.hControlPoint;
    otapCtrlPointChar.value.valueLength = 0;
    otapCtrlPointChar.cNumDescriptors = 0;
    otapCtrlPointChar.aDescriptors = NULL;

    bleResult = GattClient_SimpleCharacteristicWrite (mPeerInformation.deviceId,
                                                      &otapCtrlPointChar,
                                                      cmdLength,
                                                      pCommand);

    if (gBleSuccess_c == bleResult)
    {
        otapServerData.lastCmdSentToOtapClient = (otapCmdIdt_t)(((otapCommand_t*)pCommand)->
↪cmdId);
    }
    else
    {
        /*! A Bluetooth Low Energy error has occurred - Disconnect */
        (void)Gap_Disconnect (otapClientDevId);
    }
}
```

The ATT Confirmation for the ATT Write is received in the *BleApp_GattClientCallback()* set up earlier which receives a GATT procedure success message for a *gGattProcWriteCharacteristicValue_c* procedure type.

```
static void BleApp_GattClientCallback(
    deviceId_t              serverDeviceId,
    gattProcedureType_t     procedureType,
    gattProcedureResult_t   procedureResult,
    bleResult_t             error
)
{
   union
    {
        uint8_t                 errorTemp;
        attErrorCode_t          attErrorCodeTemp;
    }attErrorCodeVars;

    if (procedureResult == gGattProcError_c)
    {
        attErrorCodeVars.errorTemp = (uint8_t)error & 0xFFU;
        attErrorCode_t attError = attErrorCodeVars.attErrorCodeTemp;
        if (attError == gAttErrCodeInsufficientEncryption_c     ||
            attError == gAttErrCodeInsufficientAuthorization_c  ||
            attError == gAttErrCodeInsufficientAuthentication_c)
        {
    #if gAppUsePairing_d
            /* Start Pairing Procedure */
            (void)Gap_Pair (serverDeviceId, &gPairingParameters);
    #endif
        }

    }
    else
    {
        ; /* For MISRA compliance */
    }
}
```

The *BleApp_HandleValueWriteConfirmations()* function deals with ATT Write Confirmations based on the requirements of the application.

There are two possible transfer methods for Image Chunks, the ATT transfer method and the L2CAP transfer method. The OTAP server is prepared to handle both, as requested by the OTAP Client.

To be able to use the L2CAP transfer method, the OTAP Server application must register a L2CAP LE PSM and 2 callbacks: a data callback and a control callback. This is done by using the *BluetoothLEHost_Initialized()* function.

```
/* Register OTAP L2CAP PSM */
  L2ca_RegisterLePsm (gOtap_L2capLePsm_c,
                      gOtapCmdImageChunkCocLength_c); /*!< The negotiated MTU must be higher than the␣
↪biggest data chunk that is sent fragmented */
...
  App_RegisterLeCbCallbacks(BleApp_L2capPsmDataCallback, BleApp_L2capPsmControlCallback);
```

The data callback *BleApp_L2capPsmDataCallback()* is not used by the OTAP Server.

The control callback is used to handle L2CAP LE PSM connection requests from the OTAP Client and other events: PSM disconnections, No peer credits, and so on. The OTAP Client must initiate the L2CAP PSM connection if it wants to use the L2CAP transfer method.

```
static void BleApp_L2capPsmControlCallback(l2capControlMessageType_t messageType,
                                           void              pMessage)
{
    switch (messageType)
    {
        case gL2ca_LePsmConnectRequest_c:
        {
            l2caLeCbConnectionRequest_t *pConnReq = ( l2caLeCbConnectionRequest_t *)pMessage;
            /* Respond to the peer L2CAP CB Connection request - send a connection response. */
            L2ca_ConnectLePsm (gOtap_L2capLePsm_c,
                               pConnReq-> deviceId,
                               mAppLeCbInitialCredits_c);
            break;
```

(continues on next page)

(continued from previous page)

```
        }
        case gL2ca_LePsmConnectionComplete_c:
        {
            l2caLeCbConnectionComplete_t *pConnComplete = ( l2caLeCbConnectionComplete_t *)pMessage;
            if (pConnComplete->result == *gSuccessful_c)
            {
                /* Set the application L2CAP PSM Connection flag to TRUE because there is no gL2ca_
↪LePsmConnectionComplete_c
                 * event on the responder of the PSM connection. */
                otapServerData. l2capPsmConnected = TRUE;
                otapServerData. l2capPsmChannelId = pConnComplete->cId;
            }
            break;
        }
        case gL2ca_LePsmDisconnectNotification_c:
        {
            l2caLeCbDisconnection_t *pCbDisconnect = ( l2caLeCbDisconnection_t *)pMessage;
            /* Call App State Machine */

            break;
        }
        case gL2ca_NoPeerCredits_c:
        {
            l2caLeCbNoPeerCredits_t *pCbNoPeerCredits = ( l2caLeCbNoPeerCredits_t *)pMessage;
            L2ca_SendLeCredit (pCbNoPeerCredits-> deviceId,
                               otapServerData. l2capPsmChannelId,
                               mAppLeCbInitialCredits_c);
            break;
        }
        case gL2ca_LocalCreditsNotification_c*:
        {
            l2caLeCbLocalCreditsNotification_t *pMsg = ( l2caLeCbLocalCreditsNotification_t *)pMessage;
            break;
        }
        default:
            break;
    }
}
```

The ATT transfer method is supported by default but the L2CAP transfer method only works if the OTAP Client opens an L2CAP PSM credit-oriented channel.

To send data chunks to the OTAP Client the OTAP Server application calls the *OtapServer_SendCImgChunkToOtapClient()* function which delivers the chunk via the selected transfer method. For the ATT transfer method the chunk is sent via the *GattClient_CharacteristicWriteWithoutResponse()* function and for the L2CAP transfer method the chunk is sent via the *L2ca_SendLeCbData()* function.

```
static void OtapServer_SendCImgChunkToOtapClient(deviceId_t otapClientDevId,
                                                 void      pChunk,
                                                 uint16_t    chunkCmdLength)
{
    bleResult_t bleResult = gBleSuccess_c;
    if (otapServerData.transferMethod == gOtapTransferMethodAtt_c)
    {
        /* GATT Characteristic to be written without response - OTAP Client Data */
        gattCharacteristic_t otapDataChar;
        /* Only the value handle element of this structure is relevant for this operation. */
        otapDataChar.value.handle = mPeerInformation.customInfo.otapServerConfig.hData;
        bleResult = GattClient_CharacteristicWriteWithoutResponse
```

    }
}
```

The OTAP Server demo application relays all commands received from the OTAP Client to a PC through the FSCI type protocol running over a serial interface. It also directly relays all responses from the PC back to the OTAP Client.

Other implementations can bring the image to an external memory through other means of communication and directly respond to the OTAP Client requests.

Parent topic: Bluetooth Low Energy OTAP application integration

OTAP client An application running an OTAP Client must wait for an OTAP Server to connect and perform service and characteristic discovery before performing any OTAP-related operations. OTAP transactions can begin only after the OTAP Server writes the OTAP Control point CCC Descriptor to receive ATT Notifications. After this is done, bidirectional communication is established between the OTAP Server and Client and OTAP transactions can begin.

The OTAP Client can advertise the OTAP Service via the demo application. Optionally, the OTAP Server may already know the advertising device has an OTAP Service based on application-specific means. In both situations, the OTAP Server must discover the handles of the OTAP Service and its characteristics.

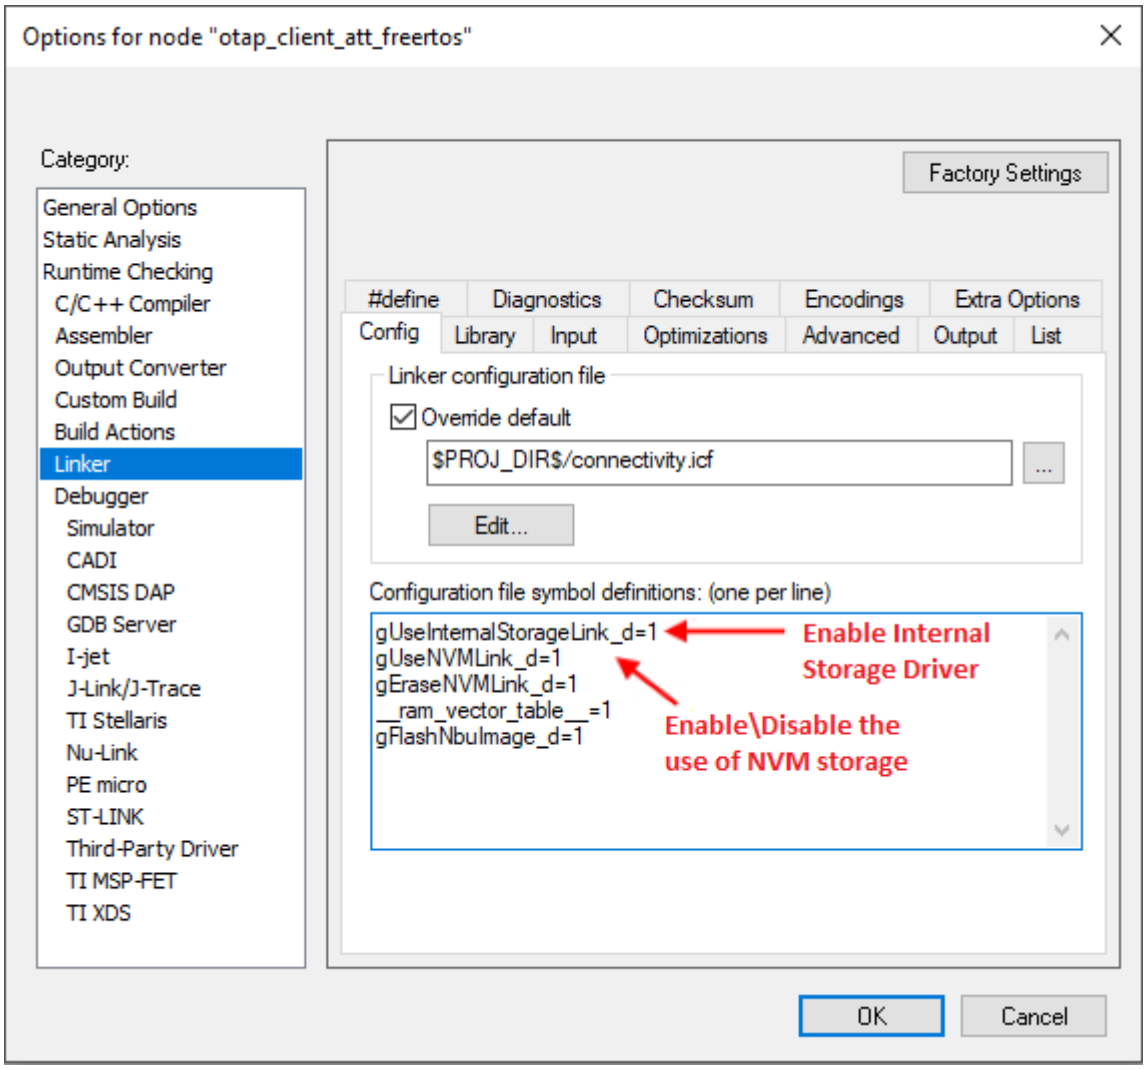
In addition to the OTAP Service instantiated in the GATT Database, the OTAP Client needs to have some storage capabilities for the downloaded image file.

How to put the OTAP Service in the GATT Database is described in The OTAP Service and Characteristics.

The upgrade image storage capabilities in the demo OTAP Client applications are handled by the *OtaSupport* module from the Framework, which contains support modules and drivers. The *OtaSupport* module has support for both internal storage (a part of the internal flash memory is reserved for storing the upgrade image) and external storage (a SPI flash memory chip).

The demo applications use internal storage by default. The internal storage is viable only if there is enough space in the internal flash for the upgrade image – the flash in this case should be at least twice the size of the largest application. The *OtaSupport* module also needs the *Eeprom* module from the Framework to work correctly.

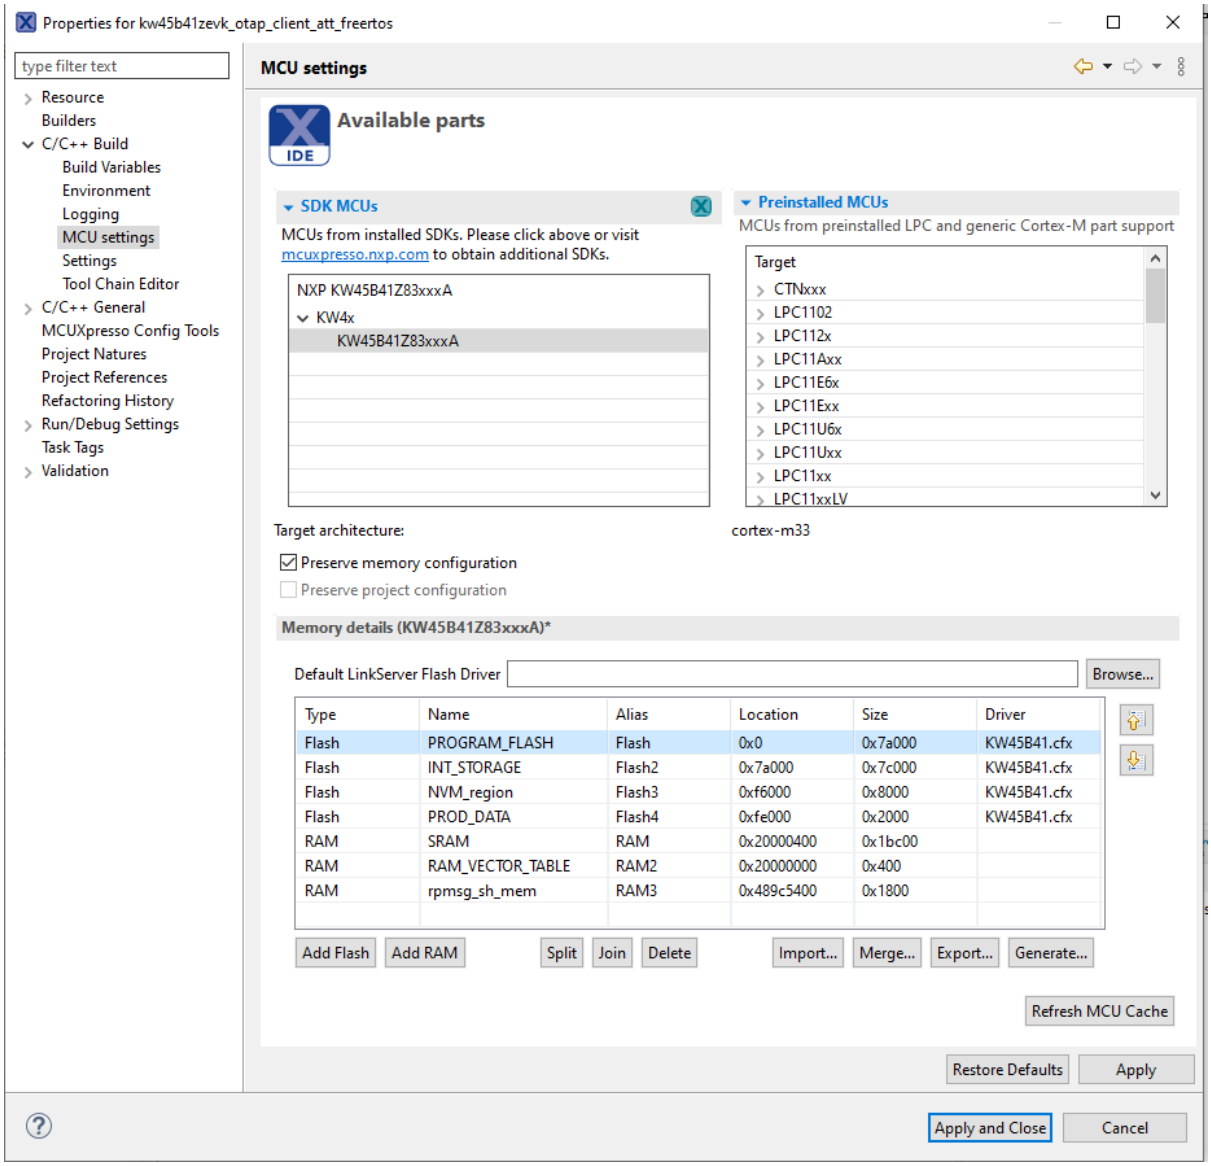
The OtaSupport module also includes functionality for configuring the OTACFG IFR sections after the image is received in order to enable the ROM bootloader to perform the actual image update.



To use the *OtaSupport* module several configuration options must be set up in both the source files and the linker options of the toolchain.

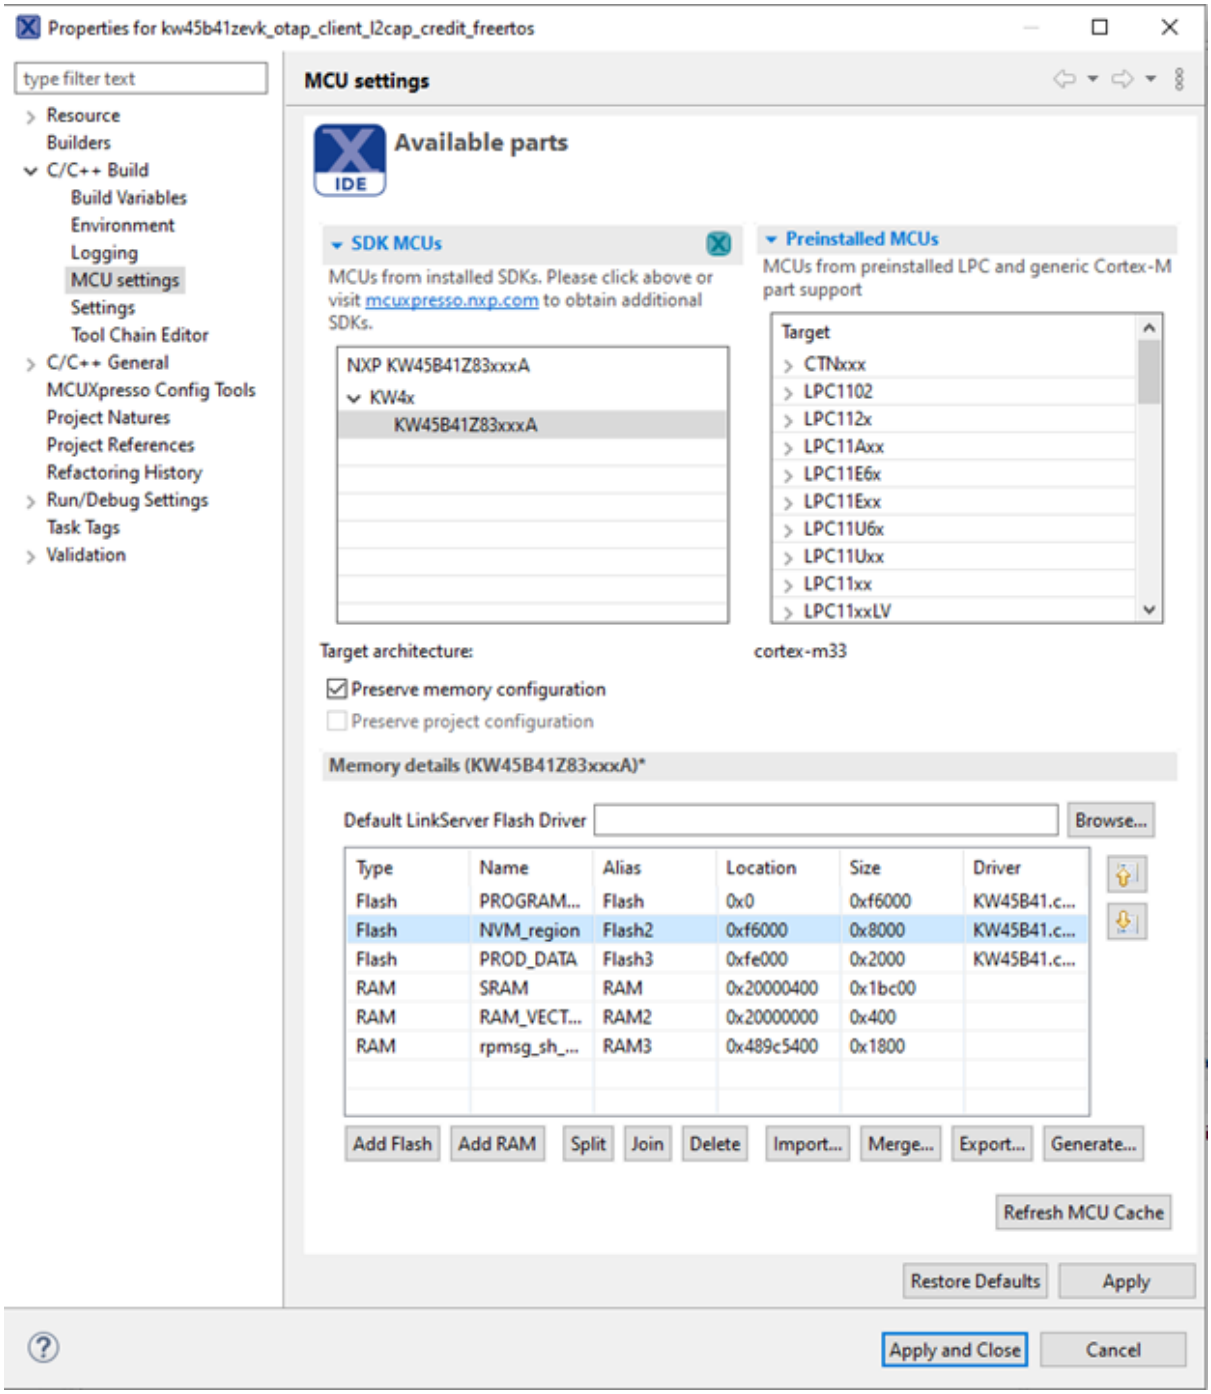
To use internal storage, set up the gUseInternalStorageLink_d=1 symbol in the linker configuration window (**Linker->Config tab** in the IAR project properties) and set the gAppOtaExternalStorage_c value to (0) in the app_preinclude.hfile:

```
/*! Define as 1 to place OTA storage in external flash */
  #define gAppOtaExternalStorage_c (0)
```



The OTAP demo applications for the IAR EW IDE have some settings in the Linker options tab which must be configured to use OtaSupport and the OTAP Bootloader. In the **Project Target Options->Linker->Config** tab, 3 symbols must be correctly defined. To use NVM storage, thegUseNVMLink_d symbol must be set to 1. The gUseInternalStorageLink_d symbol must be set to 0 when OTAP external storage is used and to 1when the internal storage is used. The gEraseNVMLink_d must be set to 0.

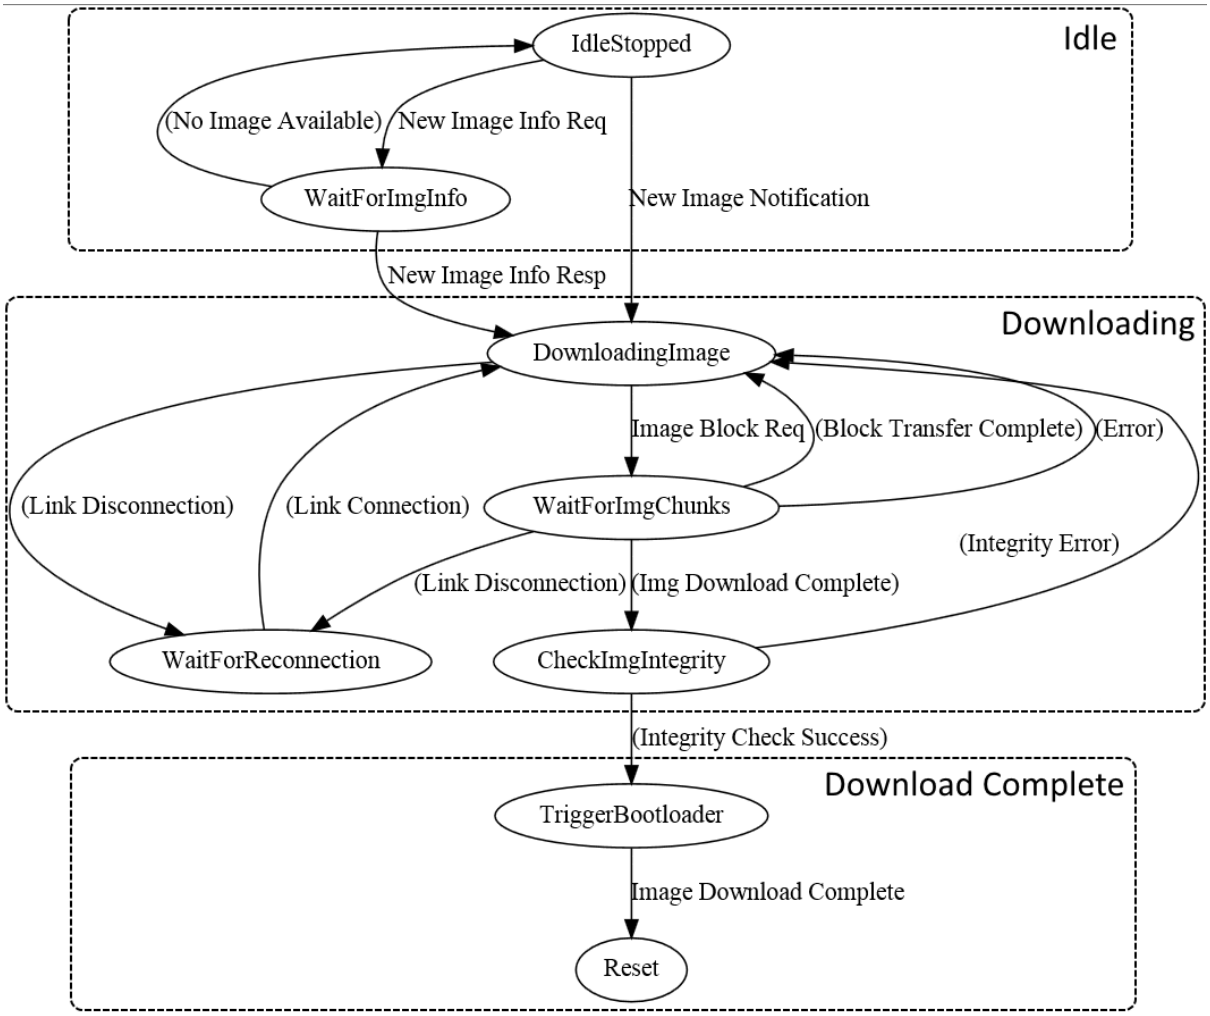
An example linker configuration window for IAR is shown below.



Note: The gEraseNVMLink_d=1 IAR linker flag places some dummy bytes into the NVM region to invalidate the data and force the application to erase the entire NVM region. When generating an image for the OTA upgrade, this flag must be set to 0. This results in a smaller image size being transferred and lower power consumption. If the NVM region must be erased after the upgrade process, the “Preserve NVM” checkbox (from the Over The Air programming tool) should be unchecked.

For MCUXpresso IDE, the linker settings required for OTAP applications can be set up from the “**SDK Import Wizard**” or from the “**Project Properties** ->**MCU settings**”. Refer to Figure.

The demo applications use internal storage by default. To enable external storage support for MCUX, set the gAppOtaExternalStorage_c value to (1) in the app_preinclude.hfile. Also remove the INT_STORAGE section (from **Project Properties**-> **MCU settings**) and extend the PROGRAM_FLASHsection as shown in the Figure.



Once the application starts and bidirectional OTAP communication is established via the OTAP Service, then the OTAP Client must determine if the connected OTAP Server has a newer image than the one currently present on the device. This can be done in two ways:

- The OTAP Server knows by some application-specific means that it has a newer image and sends a New Image Notification to the OTAP Client or
- The OTAP Client sends a New Image Info Request to the OTAP Server and waits for a response. This example application uses the second method.

The New Image Info Request contains enough information about the currently running image to allow the OTAP Server to determine if it has a newer image for the requesting device. The New Image Info Response contains enough information for the OTAP Client to determine if the “dead-vertised” image is newer and it wants to download it. The best method is entirely dependent on application requirements.

An example function that checks if an *ImageVerison* field from a New Image Notification or a New Image Info Response corresponds to a newer image (based on the suggested format of this field) is provided in the OTAP Client demo applications. The function is called *OtapClient_IsRemoteImageNewer()*.

The OTAP Client application is a little more complicated than the OTAP Server application because more state information needs to be handled (current image position, current chunk sequence number, image file parsing information, and so on). An example state diagram for the OTAP Client is shown below. The Figure briefly lists the steps of the image download process. Note that some of the states may not be explicitly present in the demo applications.

After the OTAP Client determines that the peer OTAP Server has a suitable upgrade image available, it can start the download process. This is done by sending multiple Image Block Request messages and waiting for the Image Chunks via the selected transfer method.

While receiving the image file blocks, the OTAP Client application parses the image file. In case any parameter of an image file sub-element is invalid or the image file format is invalid, it sends an Error Notification to the OTAP Server and tries to restart the download process from the beginning or a known good position.

When an Image Chunk is received, its sequence number is checked and its content is parsed in the context of the image file format. If the sequence number is not as expected, then the block transfer is restarted from the last known good position. When all chunks of an Image Block are received, the next block is requested, if there are more blocks to download. When the last Image Block in an image file is received, then the image integrity is checked (the received CRC from the Image File CRC sub-element is compared to the computed CRC).

The computed image integrity initialization and intermediary value must be reset to '0' before

starting or restarting an image download. If the image integrity check fails then the image download process is restarted from the beginning. If the image integrity check is successful, then the Image Download Complete message is sent to the OTAP Server, the OTACFG IFR is updated and the MCU is restarted. After the restart, the ROM bootloader kicks in and writes the new image to the flash memory, afterwards giving CPU control to the newly installed application.

If at any time during the download process, a Link Layer disconnection occurs, then the image download process is restarted from the last known good position when the link is re-established.

As noted earlier, the OTAP Client application needs to handle a lot of state information. In the demo application, all this information is held in the *otapClientData* structure of the *otapClientAppData_t* type. The type is defined and the structure is initialized in the *otap_client.c* file of the application. This structure is defined and initialized differently for the OTAP Client ATT and L2CAP example applications. Mainly, the *transferMethod* member of the structure is constant and has different values for the two example applications and the L2CAP application structure has an extra member.

To receive write notifications when the OTAP Server writes the OTAP Control Point attribute and ATT Confirmations when it indicates the OTAP Control Point attribute, the OTAP Client application must register a GATT Server callback and enable write notifications for the OTAP Control Point attribute. This is done in the *BluetoothLEHost_Initialized()* function in the *otap_client_att.c/otap_client_l2cap_credit.c* file.

```
static void BluetoothLEHost_Initialized(void)
{
    /* ... Missing code here ... */

    /* Register stack callbacks */
    (void)App_RegisterGattServerCallback (BleApp_GattServerCallback);

    /* ... Missing code here ... */
}
```

The *BleApp_GattServerCallback()* function handles all incoming communication from the OTAP Server.

```
static void BleApp_GattServerCallback (deviceId_t deviceId, gattServerEvent_t* pServerEvent)
{
    switch (pServerEvent->eventType)
    {
        /* ... Missing code here ... */

        case gEvtCharacteristicCccdWritten_c:
        {
            OtapClient_CccdWritten (deviceId,
                                    pServerEvent->eventData.charCccdWrittenEvent.handle,
                                    pServerEvent->eventData.charCccdWrittenEvent.newCccd);
        }
        break;

       case gEvtAttributeWritten_c:
        {
            OtapClient_AttributeWritten (deviceId,
                                         pServerEvent->eventData.attributeWrittenEvent.handle,
                                         pServerEvent->eventData.attributeWrittenEvent.cValueLength,
                                         pServerEvent->eventData.attributeWrittenEvent.aValue);
        }
       break;

        case gEvtAttributeWrittenWithoutResponse_c:
        {
            OtapClient_AttributeWrittenWithoutResponse (deviceId,
```

(continues on next page)

(continued from previous page)

```
                                        pServerEvent->eventData.attributeWrittenEvent.handle,
                                        pServerEvent->eventData.attributeWrittenEvent.cValueLength,
                                        pServerEvent->eventData.attributeWrittenEvent.aValue);
        }
        break;

        case gEvtHandleValueConfirmation_c:
        {
            OtapClient_HandleValueConfirmation (deviceId);
        }
       break;*

        /* ... Missing code here ... */

        default:
            ; /* For MISRA compliance */
        break;
    }
}
```

When the OTAP Server Writes a CCCD the *BleApp_GattServerCallback()* function calls the *OtapClient_CccdWritten()* function which sends a New Image Info Request when the OTAP Control Point CCCD is written it – this is the starting point of OTAP transactions in the demo applications.

When an ATT Write Request is made by the OTAP Server the the *BleApp_GattServerCallback()* function calls the *OtapClient_AttributeWritten()* function which handles the data as an OTAP command. Only writes to the OTAP Control Point are handled as OTAP commands. For each command received from the OTAP Server there is a separate handler function which performs required OTAP operations. These are:

- *OtapClient_HandleNewImageNotification()*
- *OtapClient_HandleNewImageInfoResponse()*
- *OtapClient_HandleErrorNotification()*

When an ATT Write Command (GATT Write Without Response) is sent by the OTAP Server the *BleApp_GattServerCallback()* function calls the *OtapClient_AttributeWrittenWithoutResponse()* function which handles Data Chunks if the selected transfer method is ATT and returns an error if any problems are encountered. Data chunks are handled by the *OtapClient_HandleDataChunk()* function.

```
static void BleApp_AttributeWrittenWithoutResponse (deviceId_t deviceId,
                                                    uint16_t handle,
                                                    uint16_t length,
                                                    uint8_t* pValue)
{
    /* ... Missing code here ... */
    f (handle == value_otap_data)
    {
        /* ... Missing code here ... */
        if (otapClientData.transferMethod == gOtapTransferMethodAtt_c)
        {
            if (((otapCommand_t*)pValue)->cmdId == gOtapCmdIdImageChunk_c)
            {
                OtapClient_HandleDataChunk (deviceId,
                                            length,
                                            pValue);
            }
        }
        /* ... Missing code here ... */
    }
```

(continues on next page)

(continued from previous page)

```
    /* ... Missing code here ... */
}
```

Finally, when an ATT Confirmation is received for a previously sent ATT Indication the *BleApp_GattServerCallback()* function calls the *OtapClient_HandleValueConfirmation()* function, which performs the necessary OTAP operations based on the last sent command to the OTAP Server. This is done using separate confirmation handling functions for each command that is sent to the OTAP Server. These functions are:

- *OtapClient_HandleNewImageInfoRequestConfirmation()*
- *OtapClient_HandleImageBlockRequestConfirmation()*
- *OtapClient_HandleImageTransferCompleteConfirmation()*
- *OtapClient_HandleErrorNotificationConfirmation()*
- *OtapClient_HandleStopImageTransferConfirmation()*

Outgoing communication from the OTAP Client to the OTAP Server is done using the *OtapCS_SendCommandToOtapServer()* function. This function writes the value to be indicated to the OTAP Control Point attribute in the GATT database and then calls the *OtapCS_SendControlPointIndication()*which checks if indications are enabled for the target device and sends the actual ATT Indication. Both functions are implemented in the *otap_service.c* file.

```
bleResult_t OtapCS_SendCommandToOtapServer (uint16_t serviceHandle,
                                            void* pCommand,
                                            uint16_t cmdLength)
{
    union
    {
        uint8_t*              uuid_char_otap_control_pointTemp;
        bleUuid_t*             bleUuidTemp;
    }bleUuidVars;

    uint16_t  handle;
    bleResult_t result;
    bleUuidVars.uuid_char_otap_control_pointTemp = uuid_char_otap_control_point;
    bleUuid_t* pUuid = bleUuidVars.bleUuidTemp;

    /* Get handle of OTAP Control Point characteristic */
    result = GattDb_FindCharValueHandleInService(serviceHandle,
                                                 gBleUuidType128_c, pUuid, &handle);

    if (result == gBleSuccess_c)
    {
        /* Write characteristic value */
        result = GattDb_WriteAttribute(handle,
                                       cmdLength,
                                       (uint8_t*)pCommand);

       if (result == gBleSuccess_c)
        {
            /* Send Command to the OTAP Server via ATT Indication */
            result = OtapCS_SendControlPointIndication (handle);
        }
    }

   return result;
}
```

(continues on next page)

(continued from previous page)

```
static bleResult_t OtapCS_SendControlPointIndication (uint16_t handle)
{
    uint16_t     hCccd;
    bool_t       isIndicationActive;
    /* Get handle of CCCD */
    GattDb_FindCccdHandleForCharValueHandle (handle, &hCccd);
    Gap_CheckIndicationStatus (...);
    return GattServer_SendIndication (...);
}
```

The *otap_interface.h* file contains all the necessary information for parsing and building OTAP commands (packed command structures type definitions, command parameters enumerations, and so on).

For the two possible image transfer methods (ATT and L2CAP) there are two separate demo applications. To be able to use the L2CAP transfer method the OATP Client application must register a L2CAP LE PSM and 2 callbacks: a data callback and a control callback. This is done in the *OtapClient_Config()* function.

```
/* Register OTAP L2CAP PSM */
L2ca_RegisterLePsm (gOtap_L2capLePsm_c,
gOtapCmdImageChunkCocLength_c); /*!< The negotiated MTU must be higher than the biggest data␣
↪chunk that is sent fragmented */
...
App_RegisterLeCbCallbacks(BleApp_L2capPsmDataCallback, BleApp_L2capPsmControlCallback);
```

The control callback is used to handle L2CAP LE PSM-related events: PSM disconnections, PSM Connection Complete, No peer credits, and so on.

```
static void BleApp_L2capPsmControlCallback
            (l2capControlMessageType_t    messageType,
             void*    pMessage)
{
    switch (messageType)
    {
        case gL2ca_LePsmConnectRequest_c:
        {
            l2caLeCbConnectionRequest_t *pConnReq =
                        (l2caLeCbConnectionRequest_t *)pMessage;
            /* This message is unexpected on the OTAP Client, the OTAP Client sends L2CAP
             * PSM connection requests and expects L2CAP PSM connection responses.
             * Disconnect the peer. */
            Gap_Disconnect (pConnReq->deviceId);
            break;
        }
        case gL2ca_LePsmConnectionComplete_c:
        {
            l2caLeCbConnectionComplete_t *pConnComplete =
                          (l2caLeCbConnectionComplete_t *)pMessage;
            /* Call the application PSM connection complete handler. */
            OtapClient_HandlePsmConnectionComplete (pConnComplete);
        break;
    }
    case gL2ca_LePsmDisconnectNotification_c:
    {
        l2caLeCbDisconnection_t *pCbDisconnect = (l2caLeCbDisconnection_t *)pMessage;
        /* Call the application PSM disconnection handler. */
        OtapClient_HandlePsmDisconnection (pCbDisconnect);
        break;
    }
    case gL2ca_NoPeerCredits_c:
```

(continues on next page)

(continued from previous page)

```
    {
        l2caLeCbNoPeerCredits_t *pCbNoPeerCredits =
                        (l2caLeCbNoPeerCredits_t *)pMessage;
        L2ca_SendLeCredit (pCbNoPeerCredits->deviceId,
                           otapClientData.l2capPsmChannelId,
                           mAppLeCbInitialCredits_c);
        break;
    }
   /* ... Missing code here ... */
    case gL2ca_Error_c:
        {
            /* Handle error */
            break;
        }
        default:
            ; /* For MISRA compliance */
       break;
}
```

The OTAP Client must initiate the L2CAP PSM connection if it wants to use the L2CAP transfer method; this can be done using the *L2ca_ConnectLePsm()* function. The *L2ca_ConnectLePsm()* function is called by the *OtapClient_ContinueImageDownload()* if the transfer method is L2CAP and the PSM is found to be disconnected.

```
static void OtapClient_ContinueImageDownload (deviceId_t deviceId)
{
    /* ... Missing code here ... */
    /* Check if the L2CAP OTAP PSM is connected and if not try to connect and exit immediately. */
    if ((otapClientData.l2capPsmConnected == FALSE) &&
            (otapClientData.state != mOtapClientStateImageDownloadComplete_c))
    {
        L2ca_ConnectLePsm (gOtap_L2capLePsm_c,
                           deviceId,
                           mAppLeCbInitialCredits_c);
        bValidState = FALSE;;
    }
    /* ... Missing code here ... */
}
```

The PSM data callback *BleApp_L2capPsmDataCallback()* is used by the OTAP Client to handle incoming image file parts from the OTAP Server.

```
static void BleApp_L2capPsmDataCallback (deviceId_t  deviceId,
                                         uint8_t*    pPacket,
                                         uint16_t    uint16_t lePsm,
                                         uint16_t    packetLength)
{
   OtapClient_HandleDataChunk (deviceId,
                               packetLength,
                               pPacket);
}
```

All data chunks regardless of their source (ATT or L2CAP) are handled by the *OtapClient_HandleDataChunk()* function. This function checks the validity of Image Chunk messages, parses the image file, requests the continuation or restart of the image download and triggers the bootloader when the image download is complete.

```
static void OtapClient_HandleDataChunk (deviceId_t deviceId, uint16_t length, uint8_t* pData);
```

The Image File CRC Value is computed on the fly as the image chunks are received using the *OTA_CrcCompute()* function from the *OtaSupport* module which is called by the *Otap-*

Client_HandleDataChunk() function. The *OTA_CrcCompute()* function has a parameter for the intermediary CRC value which must be initialized to 0 every time a new image download is started.

The actual write of the received image parts to the storage medium is also done in the *OtapClient_HandleDataChunk()* function using the *OtaSupport* module. This is achieved using the following functions:

- *OTA_StartImage()* – called before the start of writing a new image to the storage medium.
- *OTA_CancelImage()* – called whenever an error occurs and the image download process needs to be stopped/restarted from the beginning.
- *OTA_PushImageChunk()* – called to write a received image chunk to the storage medium. Note that only the Upgrade Image Sub-element of the image file is actually written to the storage medium.
- *OTA_CommitImage()* - called to set up what parts of the downloaded image are written to flash and other information for the bootloader. The Value field of the Sector Bitmap Sub-element of the Image File is given as a parameter to this function.
- *OTA_SetNewImageFlag()* - called to configure the OTACFG IFR when a new image has been successfully received. When the MCU is reset, the ROM bootloader transfers the new image from the storage medium to the program flash.

To continue the image download process after a block is transferred or to restart it after an error has occurred the *OtapClient_ContinueImageDownload()* function is called. This function is used in multiple situations during the image download process.

To summarize, an outline of the steps required to perform the image download process is shown below:

- Wait for a connection from an OTAP Server
- Wait for the OTAP Server to write the OTAP Control Point CCCD
- Ask or wait for image information from the server
- If a new image is available on the server, start the download process using the *OtapClient_ContinueImageDownload()* function.
  - If the transfer method is L2CAP CoC, then initiate a PSM connection to the OTAP Server
- Repeat while image download is not complete.
  - Wait for image chunks.
  - *Call the OtapClient_HandleDataChunk()* function for all received image chunks regardless of the selected transfer method.
    - Check image file header integrity using the *OtapClient_IsImageFileHeaderValid()* function.
    - Write the Upgrade Image Sub-element to the storage medium using *OtaSupport* module functions.
    - When the download is complete, check image integrity.
      - If the integrity check is successful, commit the image using the Sector Bitmap Sub-element and trigger the bootloader
      - If integrity check fails, restart the image download from the beginning
    - If the download is not complete, ask for a new image chunk.
  - If any error occurs during the processing of the image chunk, restart the download from the last known good position.
- If an image was successfully downloaded and transferred to the storage medium and the bootloader triggered, then reset the MCU to start the flashing process of the new image.

Parent topic: Bluetooth Low Energy OTAP application integration

Parent topic:*Over the Air Programming (OTAP)*

Secured OTAP The security features of the KW45/K32W1 devices enable them to use secured OTAP, meaning the new images can be authenticated and encrypted. The decryption/authentication keys are programmed into hardware fuses. For information on how to prepare the board, refer to the accompanying document related to board provisioning. For information on how to obtain the secured image, refer to the *Bluetooth Low Energy Demo Applications User's Guide (BLEDAUG)*.

Parent topic:*Over the Air Programming (OTAP)*

Creating a Bluetooth LE application when the Host Stack runs on another processor This section describes how to create a Bluetooth Low Energy application (host), when the Bluetooth Low Energy Host Stack is running on another processor (blackbox). The section alsp provides sample code to explain how to achieve this.

The supported serial interfaces between the two chips (application and the Bluetooth Low Energy Host Stack) are UART, SPI, or USB.

Typical applications employing Bluetooth LE Host Stack blackboxes are host systems such as a PC tool or an embedded system that has an application implementation. This chapter describes an embedded application.

For more information, refer to *Bluetooth Low Energy Host Stack FSCI Reference Manual*. This document provides explicit information on exercising the Bluetooth Low Energy Host Stack functionality through a serial communication interface to a host system.

Serial manager and FSCI configuration For creating an embedded application that communicates with the Bluetooth Low Energy Host Stack using the serial interface, the following steps must be done:

Serial manager initialization The function that must be called for Serial Manager initialization is located in *SerialManager.h*:

```
/* Init serial manager */
SerialManager_Init();
```

Parent topic: Serial manager and FSCI configuration

FSCI configuration and initialization By default, the FSCI module is disabled. It must be enabled by setting gFsciIncluded_c to 1. Also, gFsciLenHas2Bytes_c must be set to 1 because Bluetooth Low Energy Host Stack interface commands and events need serial packets bigger than 255 octets.

For more information on the following configuration parameters, refer to the FSCI chapter of the *Connectivity Framework Reference Manual*.

To configure the FSCI module, the following parameters can be set on both the Bluetooth Low Energy Application project and the Bluetooth Low Energy FSCI blackbox:

```
/* Enable/Disable FSCI */
#define gFsciIncluded_c                 1

/* Enable/Disable FSCI Low Power Commands*/
#define gFSCI_IncludeLpmCommands_c      0
```

(continues on next page)

(continued from previous page)

```
/* Defines FSCI length - set this to FALSE is FSCI length has 1 byte */
#define gFsciLenHas2Bytes_c             1

/* Defines FSCI maximum payload length */
#define gFsciMaxPayloadLen_c            1660

/* Enable/Disable Ack transmission */
#define gFsciTxAck_c                    0

/* Enable/Disable Ack reception */
#define gFsciRxAck_c                    0

/* Enable FSCI Rx restart with timeout */
#define gFsciRxTimeout_c                1
#define mFsciRxTimeoutUsePolling_c      1

/* Use Misra Compliant version of FSCI module */
#define gFsciUseDedicatedTask_c         1

/* FSCI task size */
#if defined(DEBUG)
#define gFsciTaskStackSize_c            4600
#else
#define gFsciTaskStackSize_c            2600
#endif
```

To perform the FSCI module initialization, the following code can be used:

```
/* Define fsci serial manager handle */
  #if defined(gFsciIncluded_c) && (gFsciIncluded_c > 0)
    extern serial_handle_t g_fsciHandleList[gFsciIncluded_c];
  #endif /*gFsciIncluded_c > 0*/

void BluetoothLEHost_AppInit(void)
{
    /* Init FSCI */
    FSCI_commInit( g_fsciHandleList );

    /* Register BLE handlers in FSCI */
    fsciBleRegister(0);
    ...
}
```

Parent topic: Serial manager and FSCI configuration

FSCI handlers (GAP, GATT, and GATTDB) registration For receiving messages from all the Bluetooth Low Energy Host Stack serial interfacing layers (GAP, GATT, and GATTDB), a function handler must be registered in FSCI for each layer:

```
fsciBleRegister(0);
```

Parent topic: Serial manager and FSCI configuration

Parent topic:*Creating a Bluetooth LE application when the Host Stack runs on another processor*

Bluetooth Low Energy Host Stack initialization The Bluetooth Low Energy Host Stack must be initialized when platform setup is complete and all RTOS tasks have been started. This initialization is done by restarting the blackbox using a FSCI CPU Reset Request command. This is performed automatically by the ***Ble_Initialize(App_GenericCallback)*** function.

```
/* Send FSCI CPU reset command to BlackBox */
FSCI_transmitPayload(gFSCI_ReqOpcodeGroup_c, mFsciMsgResetCPUReq_c, NULL, 0, fsciInterface);
```

The completion of the Bluetooth Low Energy Host Stack initialization is signaled by the reception of the *GAP-GenericEventInitializationComplete.Indication* event (over the serial communication interface, in FSCI). The *Bluetooth Low Energy-HostInitialize.Request* command is not required to be sent to the blackbox (the entire initialization is performed by the blackbox, when it resets).

Parent topic:*Creating a Bluetooth LE application when the Host Stack runs on another processor*

GATT database configuration The GATT database always resides on the same processor as the entire Bluetooth Low Energy Host Stack, so the attributes must be added by the host application using the serial communication interface.

To create a GATT database remotely, *GATTDBDynamic* commands must be used. The GATTDBDynamic API is provided to the user that performs all the required memory allocations and sends the FSCI commands to the blackbox. The result of the operation is returned, including optionally the service, characteristic, and 'cccd' handles returned by the blackbox.

Current supported API for adding services is the following:

```
bleResult_t GattDbDynamic_AddGattService (gattServiceHandles_t* pOutServiceHandles);
bleResult_t GattDbDynamic_AddGapService (gapServiceHandles_t* pOutServiceHandles);
bleResult_t GattDbDynamic_AddIpssService (ipssServiceHandles_t* pOutServiceHandles);
bleResult_t GattDbDynamic_AddHeartRateService (heartRateServiceHandles_t* pOutServiceHandles);
bleResult_t GattDbDynamic_AddBatteryService (batteryServiceHandles_t* pOutServiceHandles);
bleResult_t GattDbDynamic_AddDeviceInformationService (deviceInfoServiceHandles_t*␣
↪pOutServiceHandles);
```

The service handles are optional.

Also, a generic function is provided, so that the user can add any generic service to the database:

```
bleResult_t GattDbDynamic_AddServiceInDatabase (serviceInfo_t* pServiceInfo);
```

Usually, a Bluetooth Low Energy Application is ported from a single chip solution, where the Bluetooth Low Energy Application and the Bluetooth Low Energy stack reside on the same processor and the GATT database is populated statically. The user should remove all the attribute handles from any structure and replace them with *gGattDbInvalidHandle_d*. The attribute handles should be populated after the services are added dynamically to the database with the handles returned by the previous API.

Parent topic:*Creating a Bluetooth LE application when the Host Stack runs on another processor*

FSCI host layer The Bluetooth Low Energy GAP, GATT, GATTDB, and L2CAP APIs are included in the Bluetooth Low Energy interface. When these APIs reside on a separate processor than the Bluetooth Low Energy stack, they are implemented as an FSCI Host Layer that should be added to the Bluetooth Low Energy Application project.

This layer is responsible for serializing API to the corresponding FSCI commands. The layer also sends these APIs to the blackbox, receives and deserializes FSCI statuses and events, presents them to the Bluetooth Low Energy Application, and arbitrates access from multiple tasks to the serial interface.

All the GAP, GATT, GATTDB, and L2CAP APIs are executed asynchronously, so the user context blocks waiting for the response from the blackbox. The response can be the status of the request or optionally an FSCI event, which includes the output parameters of a synchronous function.

There are also functions without parameters that are not executed synchronously and they are provided asynchronously through a later FSCI event. It is the responsibility of the FSCI Host layer

to keep the application-allocated memory between the time of the request and the completion of the event with the actual values of the output parameters and populate them accordingly.

The Bluetooth Low Energy API execution inside the FSCI Host layer first waits for gaining access to the serial interface through a mutex. Once the access is gained, the FSCI request is sent to the serial interface to the blackbox. Then, by default, the serial interface response is received by polling until the whole FSCI packet is received. The other option available is to block the user task to wait for an OS event that is set by the FSCI module when the status is received. For more information on the FSCI module, see the Connectivity Framework Reference Manual. See *References*.

The API can have output parameters that are to be received immediately after the status of the request. In such as case, if the status of the request is 'success', the polling mechanism continues to receive the whole FSCI packet of the Bluetooth Low Energy event. The output parameters are obtained and the values are filled in the memory space provided by the application. After obtaining the status and optionally the event, the execution of the request is considered completed, the mutex to the serial interface is unlocked, and the execution flow is returned to the user calling context.

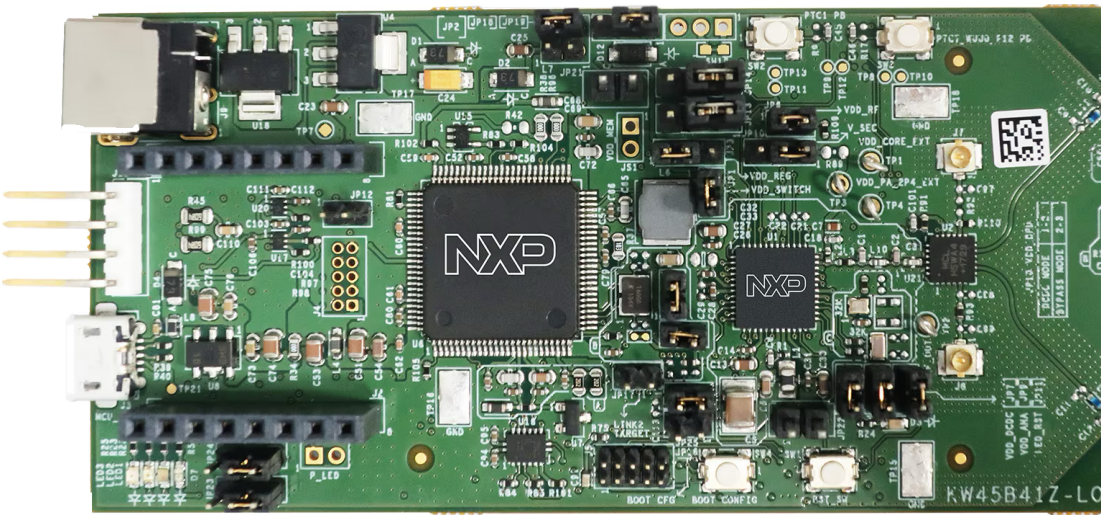
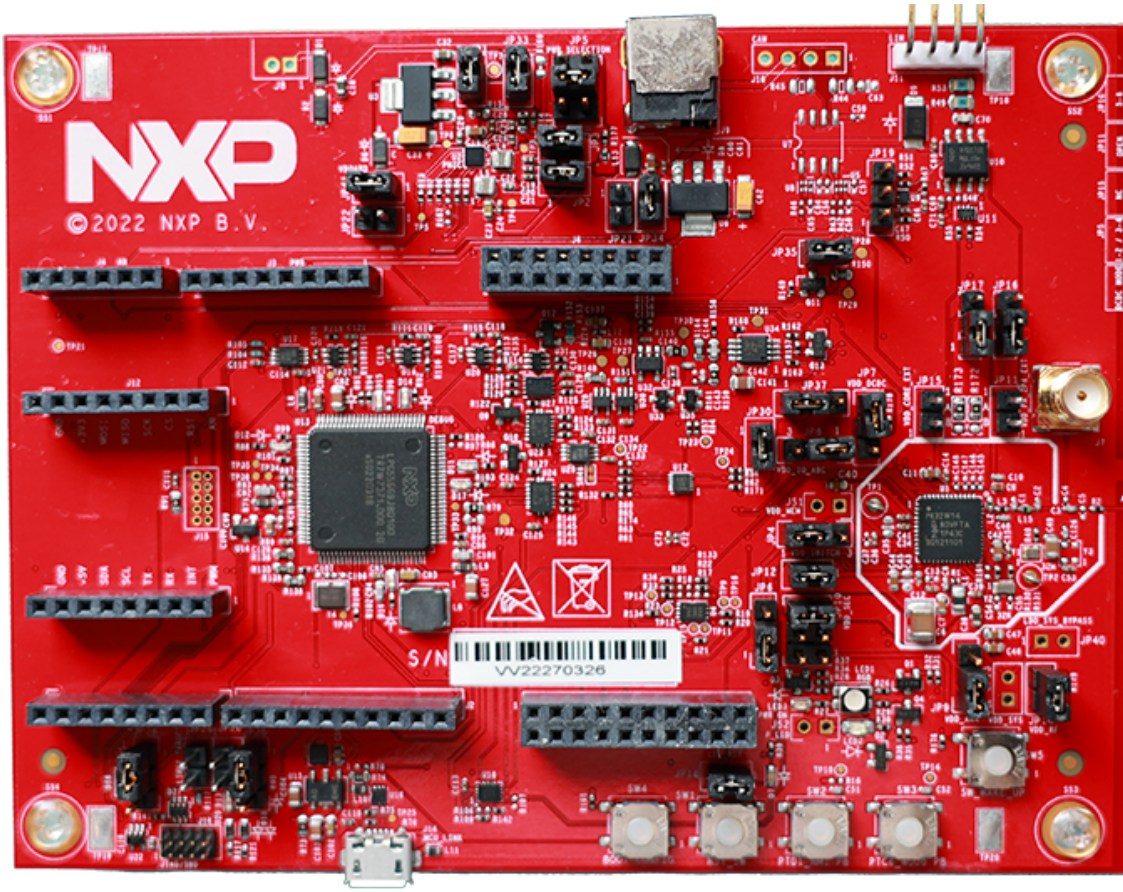
KW45, K32W1, MCXW71, KW47, MCXW72 Bluetooth Low Energy Software Quick Start Guide



Introduction This document briefly describes the process of using NXP Bluetooth Low Energy Software for the KW45, K32W1, MCXW71, KW47, or MCXW72 wireless microcontroller platforms (version 1.1.0). It lists the hardware setup and steps for building and usage of the provided demo applications.

Hardware setup The examples described in this document use a KW45B41Z-EVK, KW45B41Z-LOC, K32W148-EVK, MCX-W71-EVK, FRDM-MCXW71, KW47-EVK, KW47-LOC, MCX-W72-EVK, or FRDM-MCXW72 as the development platform, as shown in the figures below.



- The default interface selected in the IAR Embedded Workbench for Arm projects included in this release is below:
  - CMSIS-DAP for kw45b41zevk, kw45b41zloc, k32w148evk, mcxw71evk, frdmmcxw71
  - JLink for kw47evk, kw47loc, mcxw72evk, and frdmmcxw72 platforms
- Use jumpers to configure the boards in one of the available power configurations (refer to the specific board documentation).
- On all boards, the OpenSDA USB port is connected to a Windows PC. The OpenSDA chip on the board requires flashing with appropriate firmware with debugging and virtual serial COM port capabilities.

Getting Started with west Build Environment These steps are intended for **GitHub users** working with Bluetooth Low Energy (BLE) demo applications from the GitHub MCUXpresso SDK repository.

Follow the steps in the order presented in Getting Started with MCUXpresso SDK Repository to install the west environment.

Command Line to Generate/Build Projects

Example: w_uart **on** kw47evk

To build the w_uart example for the kw47evk board using the IAR toolchain and generate an IDE project, use the following command:

```
west build -b kw47evk examples/wireless_examples/bluetooth/w_uart/bm/ \ --toolchain=iar -t guiproject -
↪Dcore_id=cm33_core0 --pristine
```

Argument	Description
-b kw47evk	Specifies the board
--toolchain=iar	Specifies the toolchain (default is armgcc)
-t guiproject	Creates an IDE project
-Dcore_id=cm33_core0	Core ID, if available
--pristine	Cleans the build folder before building

Use the following steps in order to build and flash the BLE software demo applications on all toolchains presented in:

- Building and flashing the BLE software demo applications using IAR Embedded Workbench
- Building and flashing the BLE Software Demo applications using MCUXpresso IDE
- Building and flashing the BLE software demo applications using Visual Studio Code

Installing the Connectivity Package To install the Connectivity Package, configure and download the package archive from the staging system on the https://mcuxpresso.nxp.com website. You can simply download the precreated package archive if it is available on the same website.

Note: Use the default location for the package (C:\NXP) and create a subfolder there specific to each device and release.

Note: Prior to loading any wireless SDK example, update your NBU image with the provided binaries in the following folder of the SDK: ../middleware/wireless/ble_controller/bin

Building the binaries This section describes the necessary steps for obtaining the binary files for usage with the boards.

Prerequisites To build any of the demo applications, you need the following toolchain:

- IAR Embedded Workbench for Arm (details in release note)
- MCUXpresso IDE (details in release note)
- Visual Studio Code with "*MCUXpresso for Visual Studio Code*" extension (details in release note)
- Teraterm (version 4.105 or higher)

The Connectivity Software Package does not include support for any other toolchains. The packages must be built with the debug configuration to enable debugging information. This package includes various sample applications that can be used as a starting point.

Conventions for building the *wireless_UART* application. The following sections present the steps required for building the *wireless_UART* application. All applications can be found using the following placeholders for text:

- <connectivity_path>: represents the root path for the SDK.
- <board>: represents the target board for the demo app, "kw47evk" in this case.
- <RTOS>: represents the scheduler or RTOS used by the app; it can be either "bm" or "freertos".
- <demo_app>: represents the demo application name.
- <IDE>: represents the integrated development environment used to build projects; "iar" in this case.
- <core_id>: represents the target CPU on which the application will run, "cm33_core0" in this case (applicable only on KW47-EVK, KW47-LOC, MCX-W72-EVK and FRDM-MCXW72 boards).
- The general folder structure of the demo applications is the following:

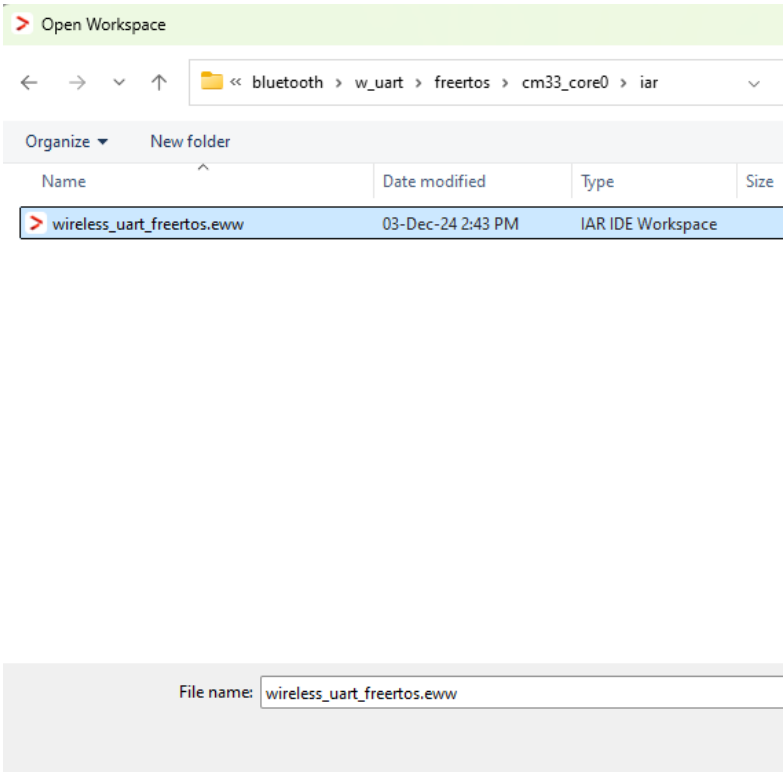
  <connectivity_path>\boars\<board>\wireless_examples\bluetooth\<demo_app>\
  <core_id>\<RTOS>\<IDE>

Selected application: w_uart

Board: One of the following boards:

- **kw45b41zevk** (for this guide)
- kw45b41zloc
- k32w148evk
- frdmmcxw71
- kw47evk
- kw47loc
- mcxw72evk
- frdmmcxw72

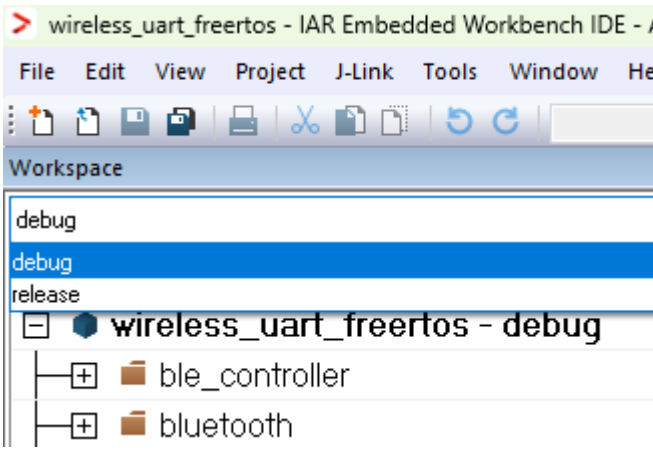
RTOS: FreeRTOS



Resulting location:

<connectivity_path>\boards\<kw45b41zevk / kw45b41zloc / k32w148evk / frdmmcxw71 / kw47evk / kw47loc / mcxw72evk / frdmmcxw72>\wireless_examples\bluetooth\w_uart\freertos\<IDE>

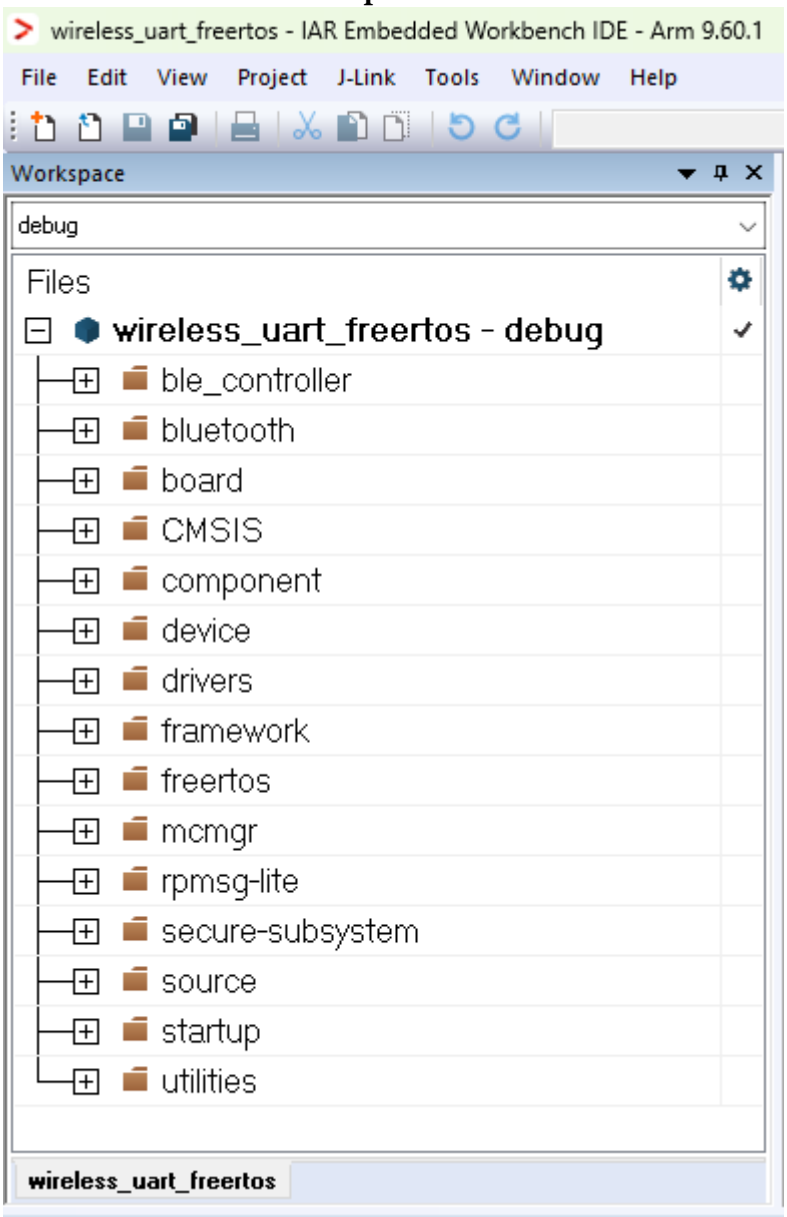
Building and flashing the BLE software demo applications using IAR Embedded Workbench



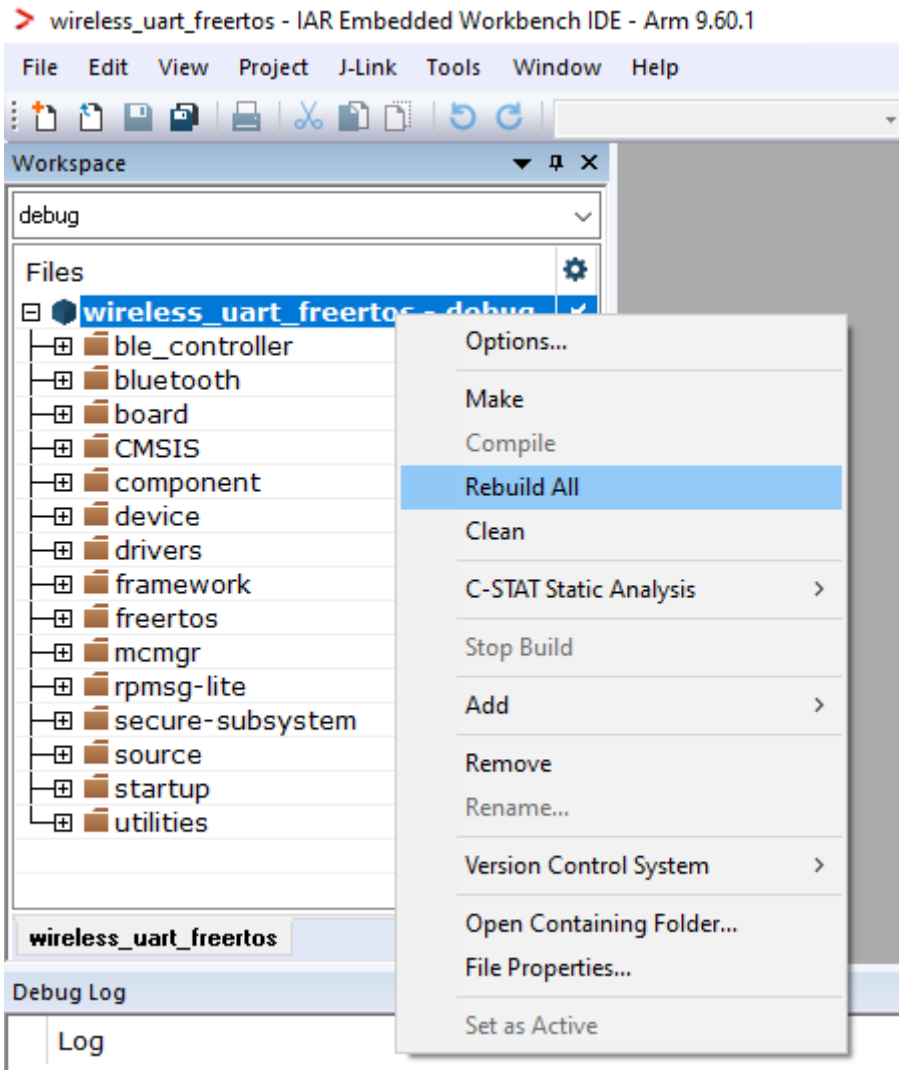
Use the following steps in order to build and flash the BLE software demo applications using the IAR Embedded Workbench:

1. First unpack the contents of the archive to a folder on the local disk. Then, navigate to the resulting location starting from the SDK root directory.
2. Open the IAR workspace file (*.eww file format) highlighted file in the figure below.

Wireless UART IAR demo project location



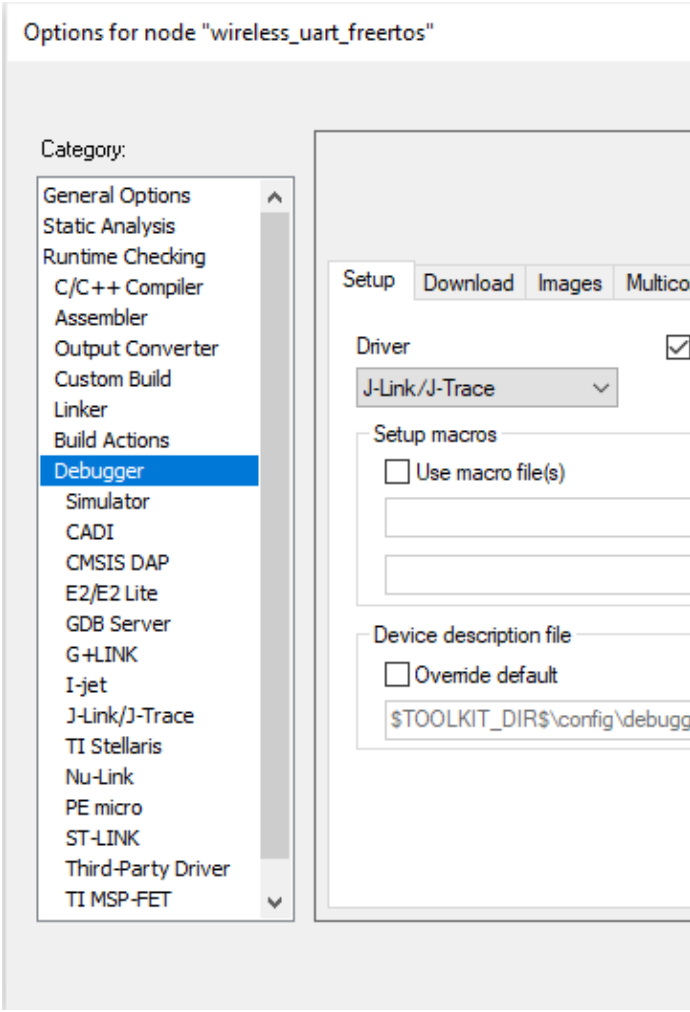
3. Choose between Debug and Release configurations in the drop-down selector above the project tree in the workspace.



Select the desired configuration (Debug or Release)

The figure below shows the Wireless UART - IAR workspace.

Wireless UART - IAR workspace

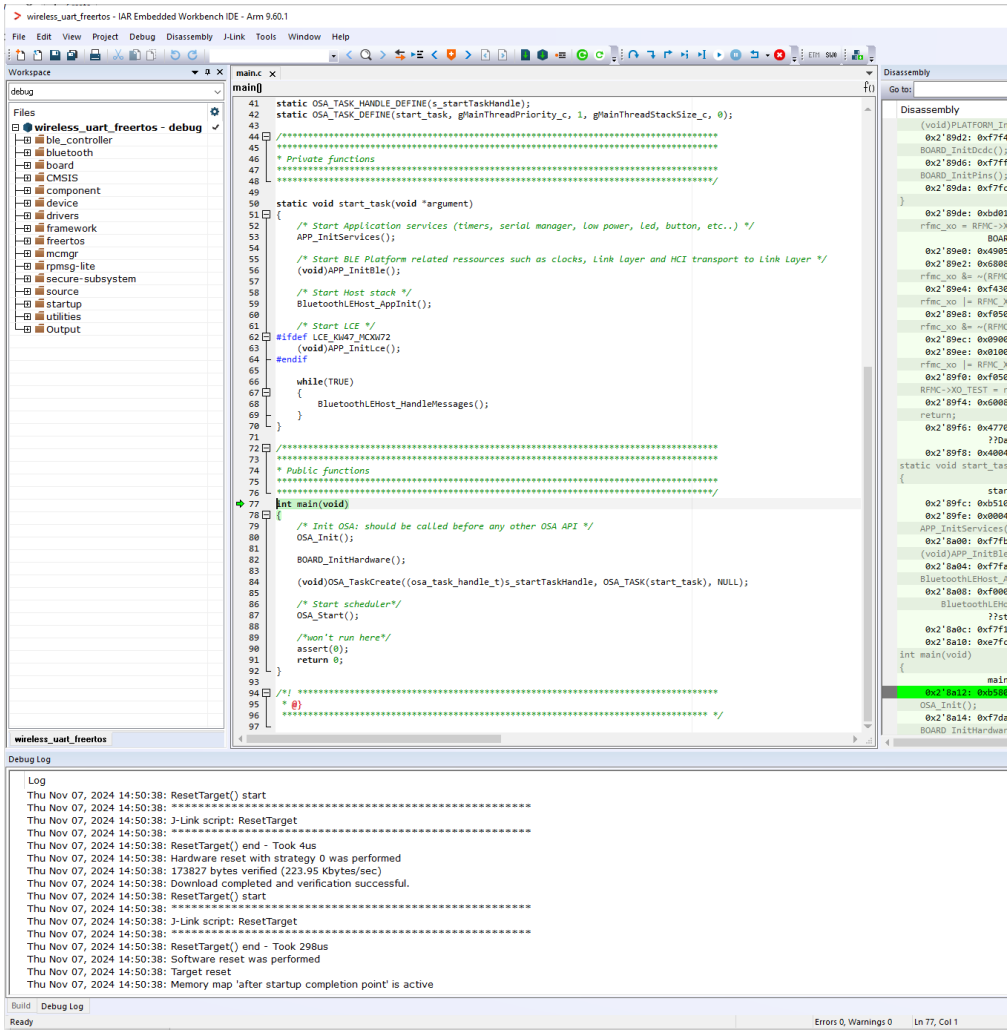


4. Build the Wireless UART project using the options shown in the figure.

Build Wireless UART application

5. Make the appropriate debugger settings in the project options window, as seen in the next figure.

   Go to: **Project** > **Options (Alt+F7)** > **Debugger** > **Setup (tab)** > **Driver** > **J-Link/J-Trace**

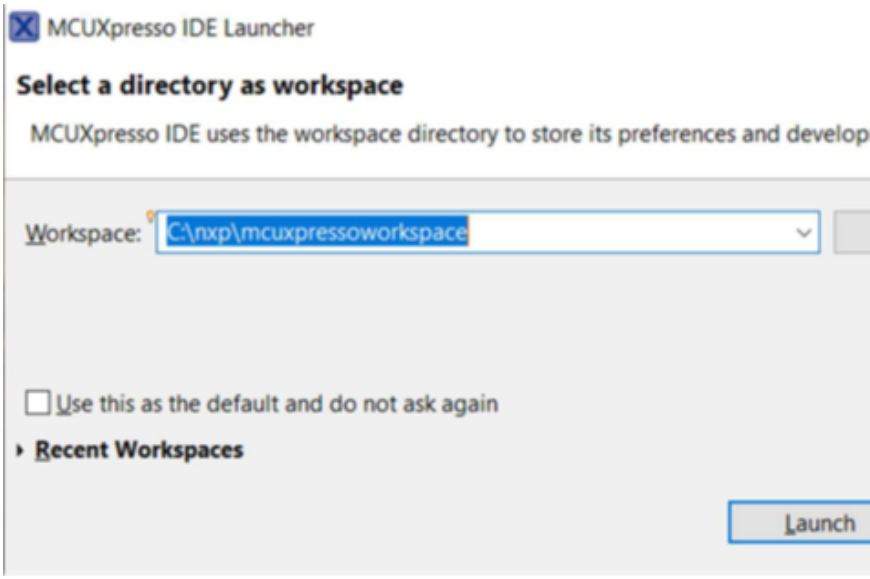


Debugger Settings for the Wireless UART project

6. Click the "**Download and Debug**" button (or **CTRL+D**) to flash the executable onto the board.

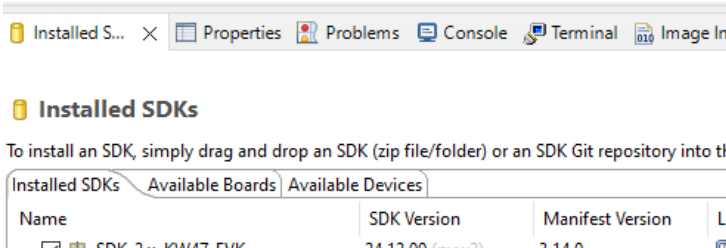
Download and Debug the Wireless UART application

7. Press **Go** (**F5**). At this moment, the board starts running the application.



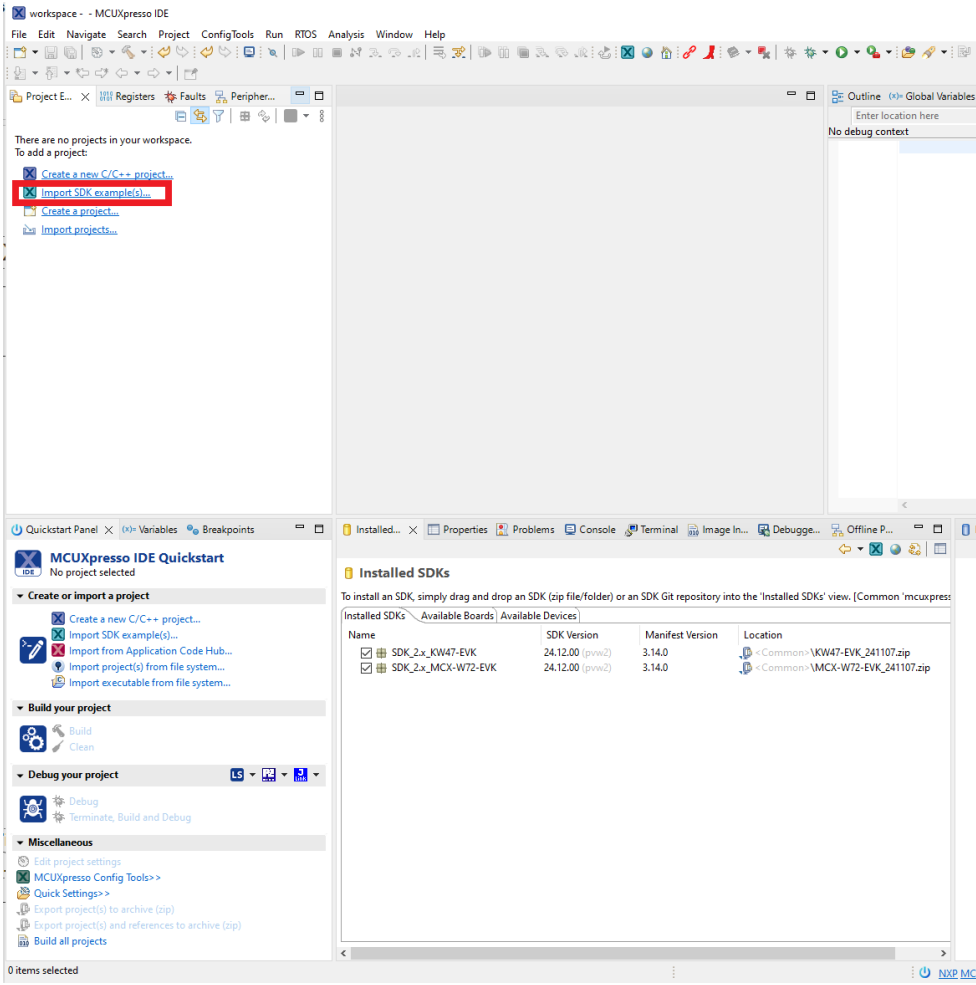
Running the code on IAR

Parent topic:*Building the binaries*



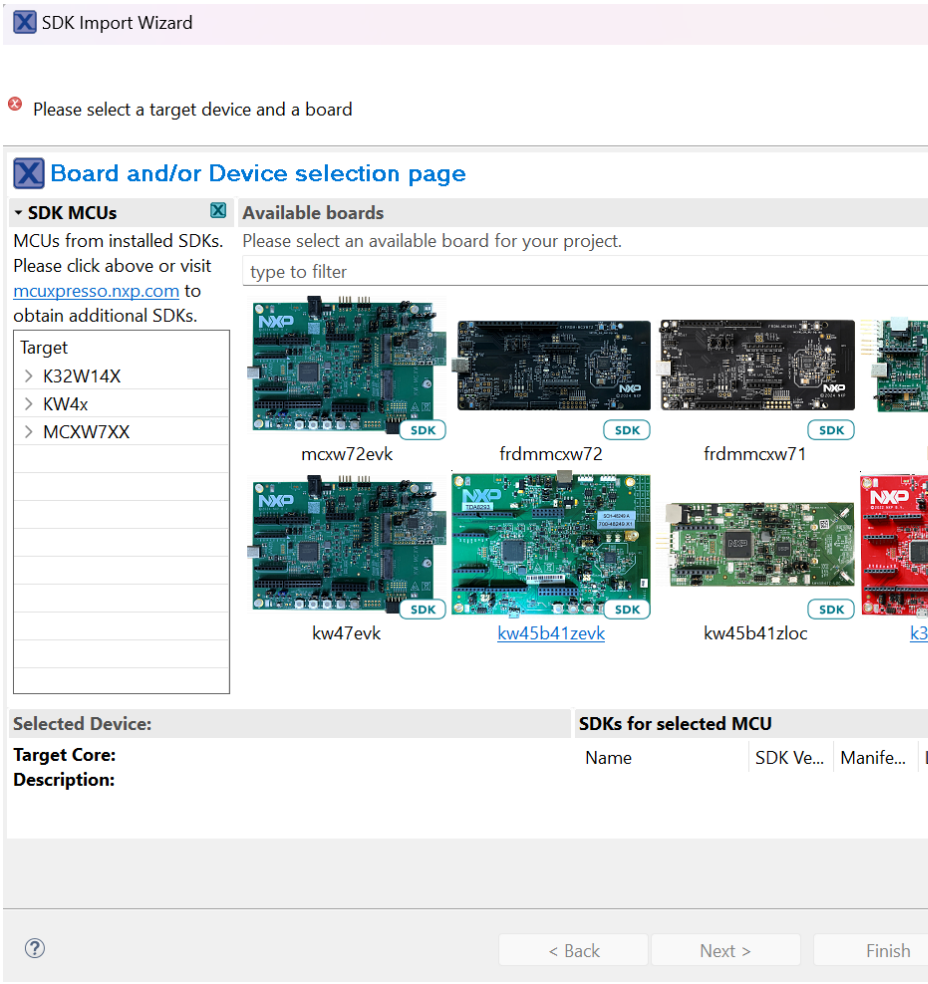
Building and flashing the BLE Software Demo applications using MCUXpresso IDE To build and flash the BLE software demo applications using MCUXpresso IDE, follow the steps listed below:

1. Open MCUXpresso IDE and open an existing or new workspace location.



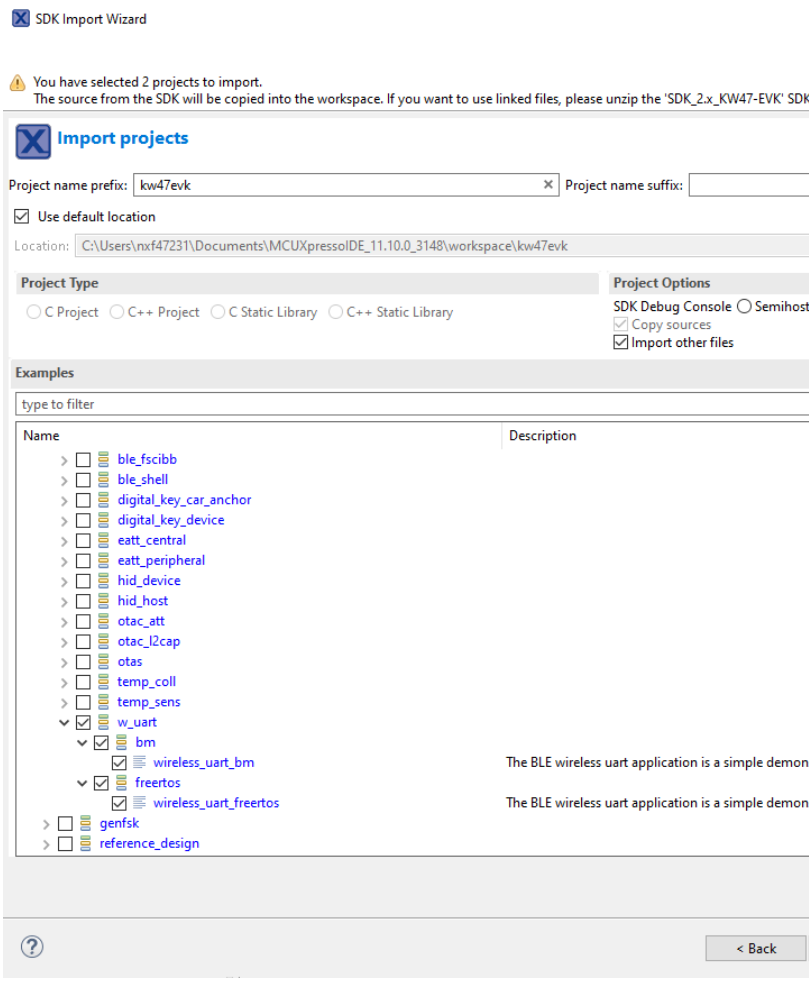
Select MCUXpresso IDE workspace

2. Drag and drop the package archive into the **MCUXpresso Installed SDKs** area in the lower right of the main window.



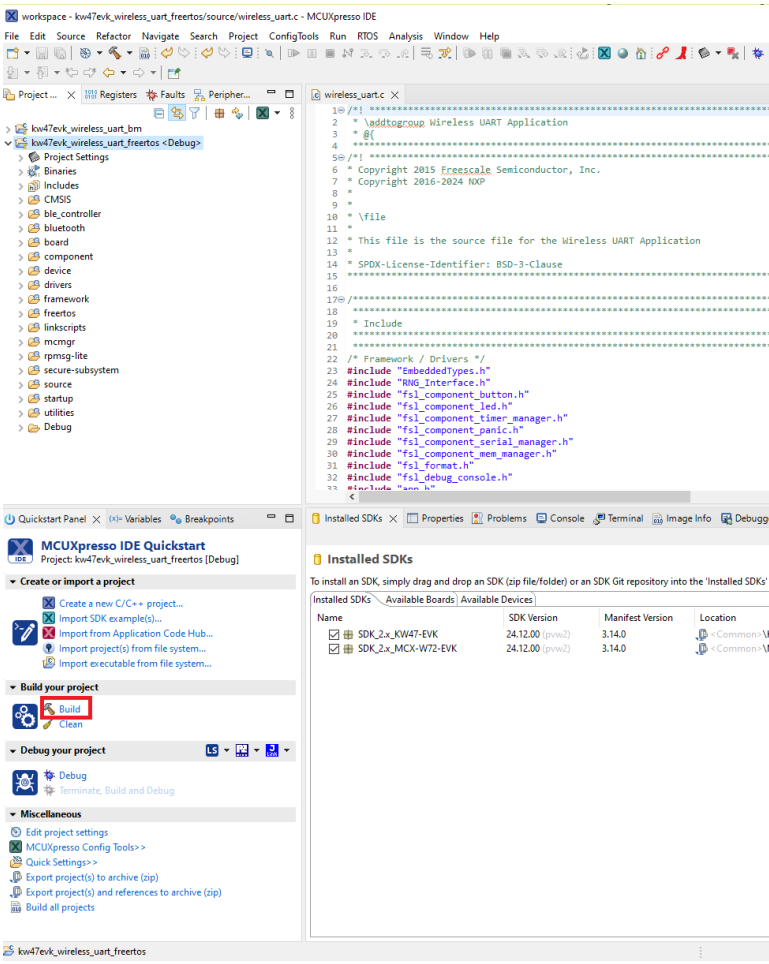
Installed SDKs in MCUXpresso IDE workspace

3. After the SDK is loaded successfully, select the "**Import the SDK examples(s)...**" to add examples to your workspace.



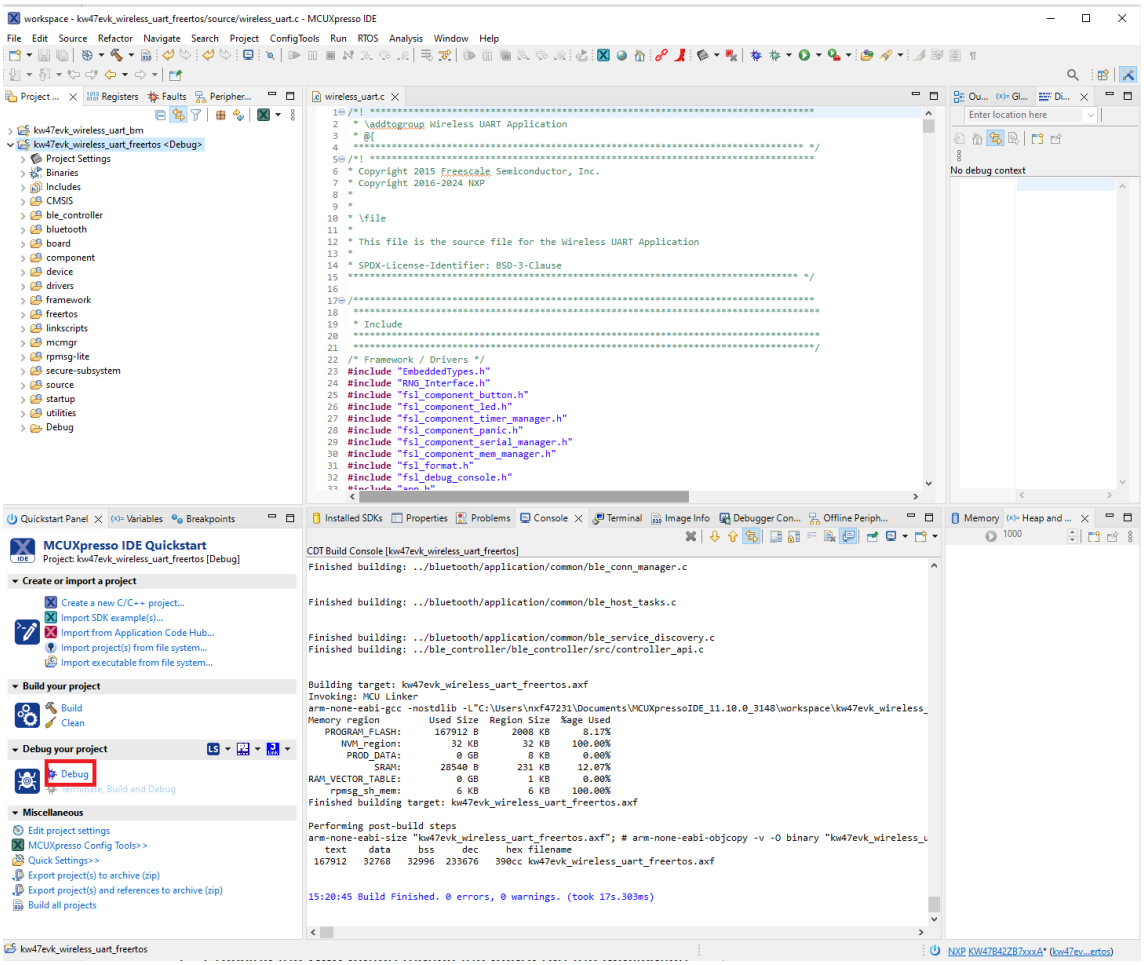
Importing SDK example(s)

4. To select the desired example(s), select the *kw45b41zevk* / *kw45b41zloc* / *k32w148evk* / *kw47evk* / *frdmmcxw71* / *frdmmcxw72* / *mcxw72evk* / *kw47loc* board and then click the "**Next**" button:

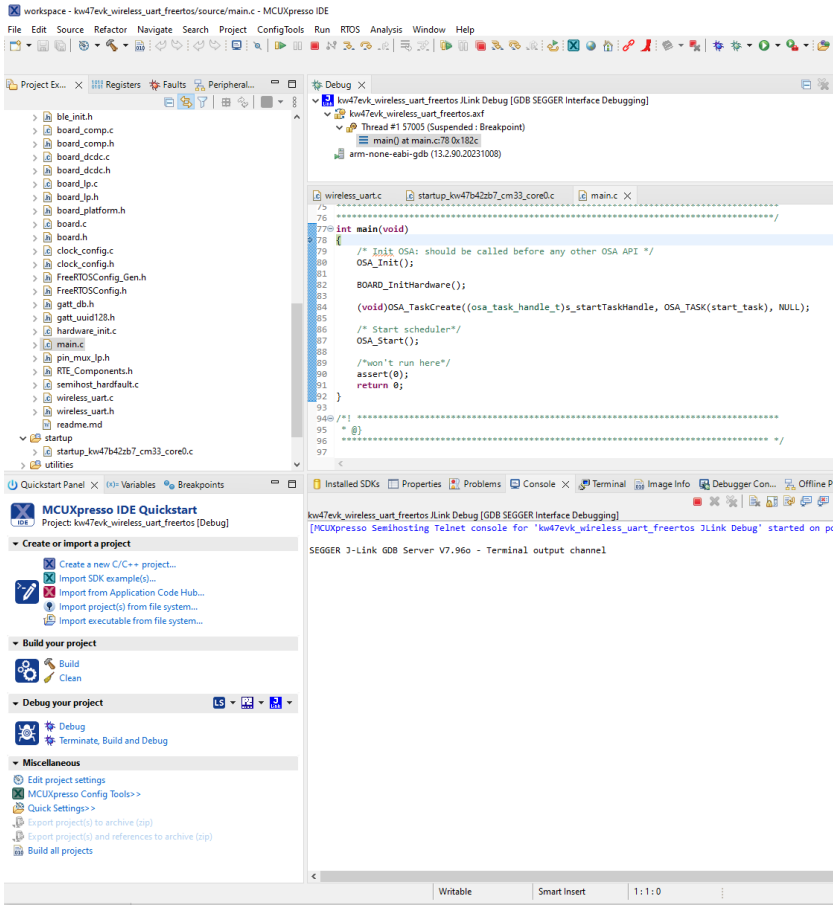


Selecting the KW47-EVK board

Select Wireless UART FreeRTOS project



5. Build the wireless_uart_freertos project.

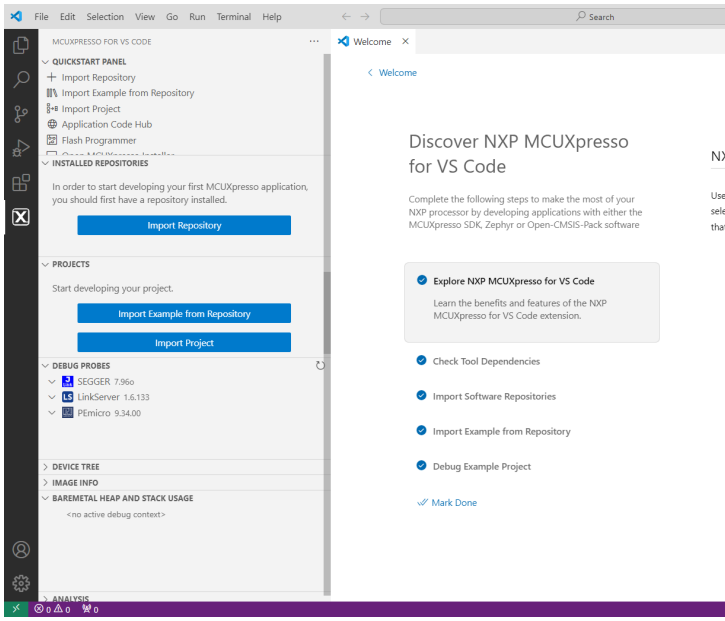


Build the Wireless UART FreeRTOS project

6. Click the “**Debug**” button to download the executable onto the board. Make sure you select the appropriate device to flash.

Download and debug the Wireless UART FreeRTOS project

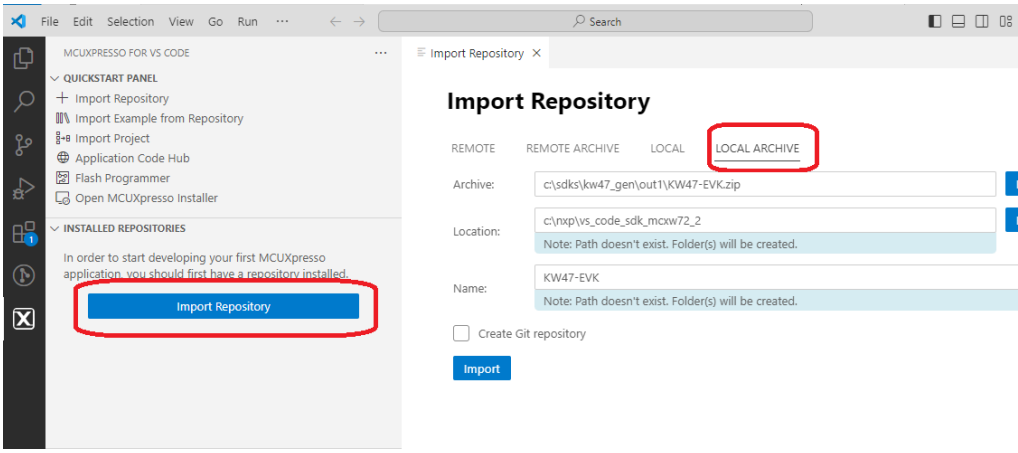
7. Pressing the **Run** button makes the board run the application.



Running the code on MCUXpresso IDE

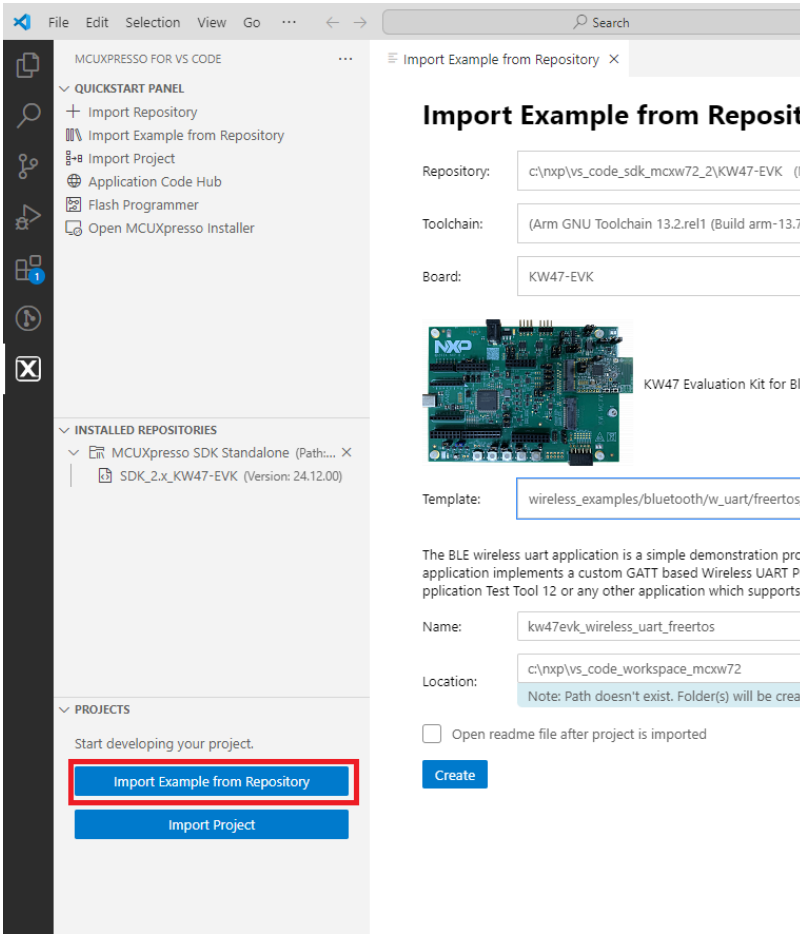
Parent topic:*Building the binaries*

Building and flashing the BLE software demo applications using Visual Studio Code To build and flash the BLE software demo applications using Visual Studio Code, follow the steps listed below:



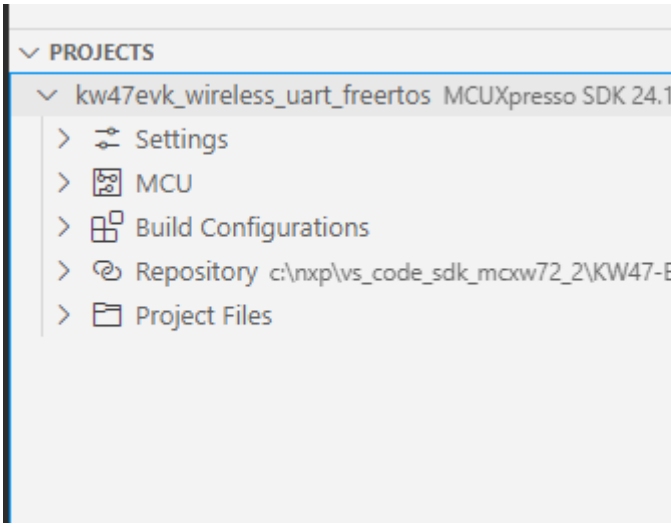
1. Open Visual Studio Code and open the MCUXpresso for Visual Studio Code extension as shown in the figure below.

MCUXpresso for Visual Studio Code extension



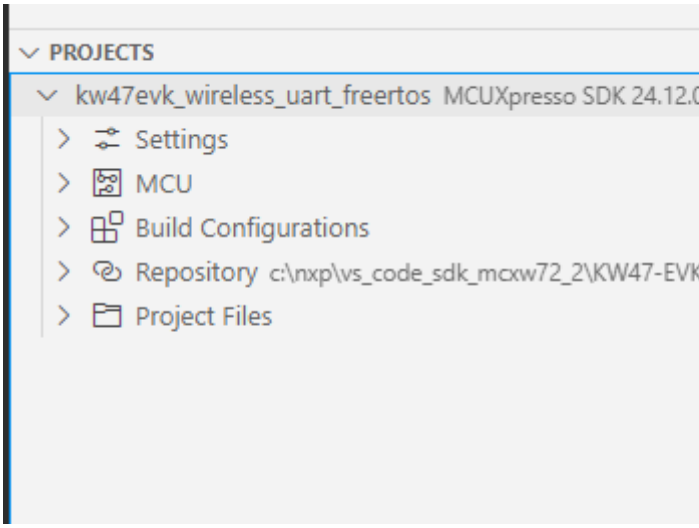
2. Import the SDK package: click “**Import Repository**”. Then, choose the “**Local**” option (if the SDK is archived use “**Local archive**”), browse to the path of the SDK you want, and click “**Import**”.

Steps to import the SDK

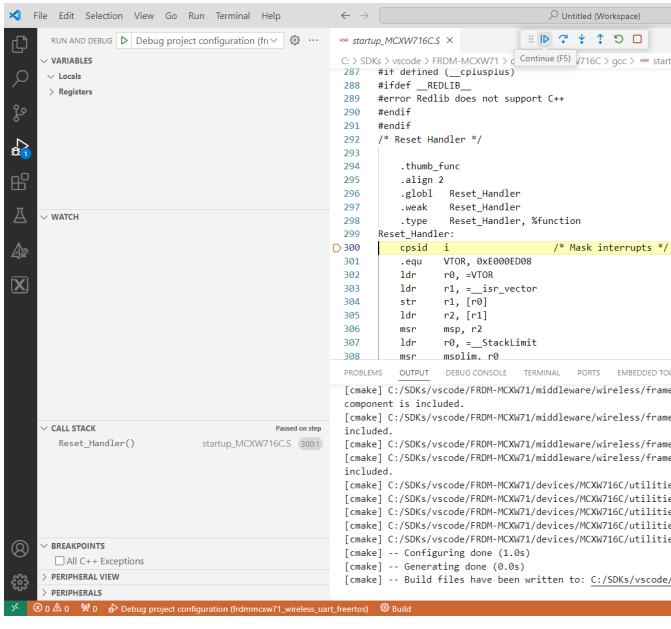


3. After the SDK is loaded successfully, select the “**Import Example from Repository**” to add an application to your workspace. Choose the repository, toolchain (Arm GNU), board, example you want to add, and the location where the VS Code project would be created. Then click “**Create**”.

Steps to import the example application



4. The application now appears in the “**Projects**” tab on the left. Build the application by pressing the “**Build selected**” button.



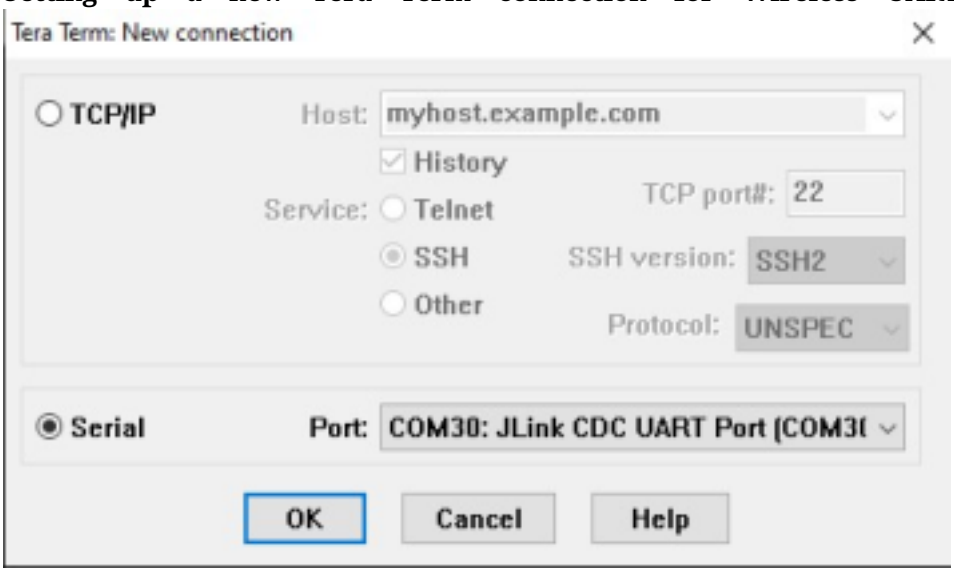
Building the Wireless UART FreeRTOS application

5. After the build is completed successfully, debug the application by clicking the "**Debug**" button.

Debug the Wireless UART FreeRTOS application

6. Press the run ("**Continue**") button twice to run the application on the board.

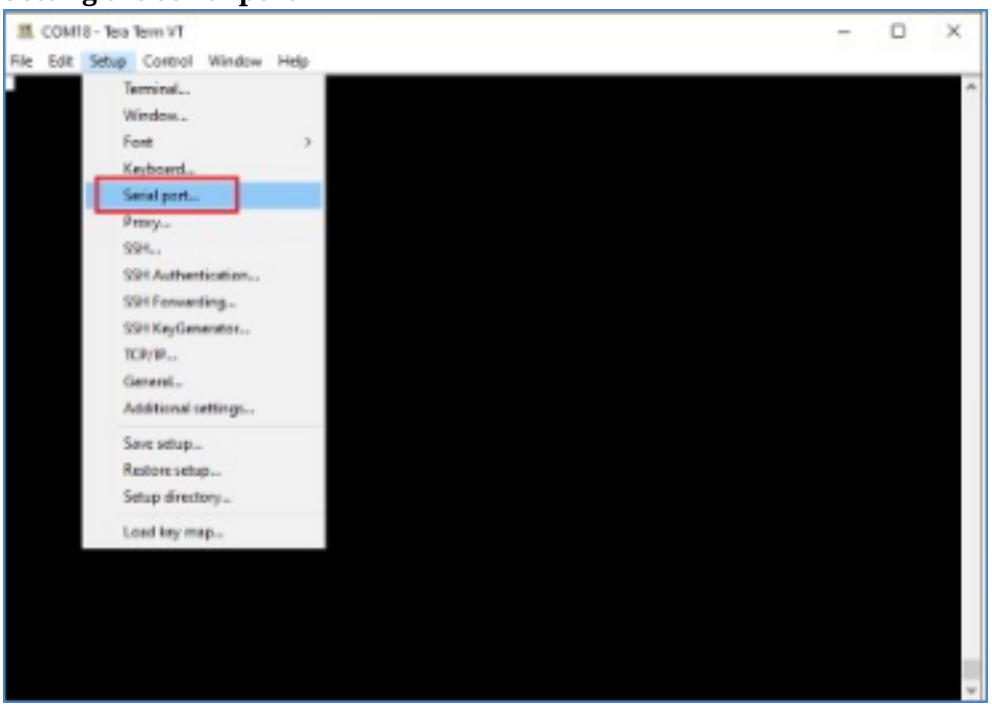
Running the Wireless UART FreeRTOS application



Parent topic:*Building the binaries*

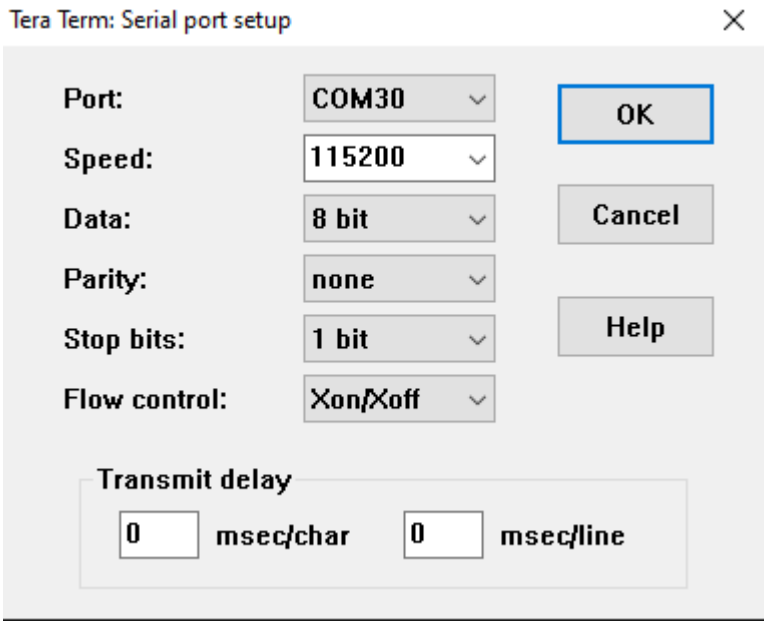
Running the Wireless UART application using NXP IoT Toolbox mobile application To run the Wireless UART application using NXP IoT Toolbox mobile application, follow the steps as listed below:

Note: Before working on these steps, ensure to install the latest version of the NXP IoT Toolbox mobile application from the application store.



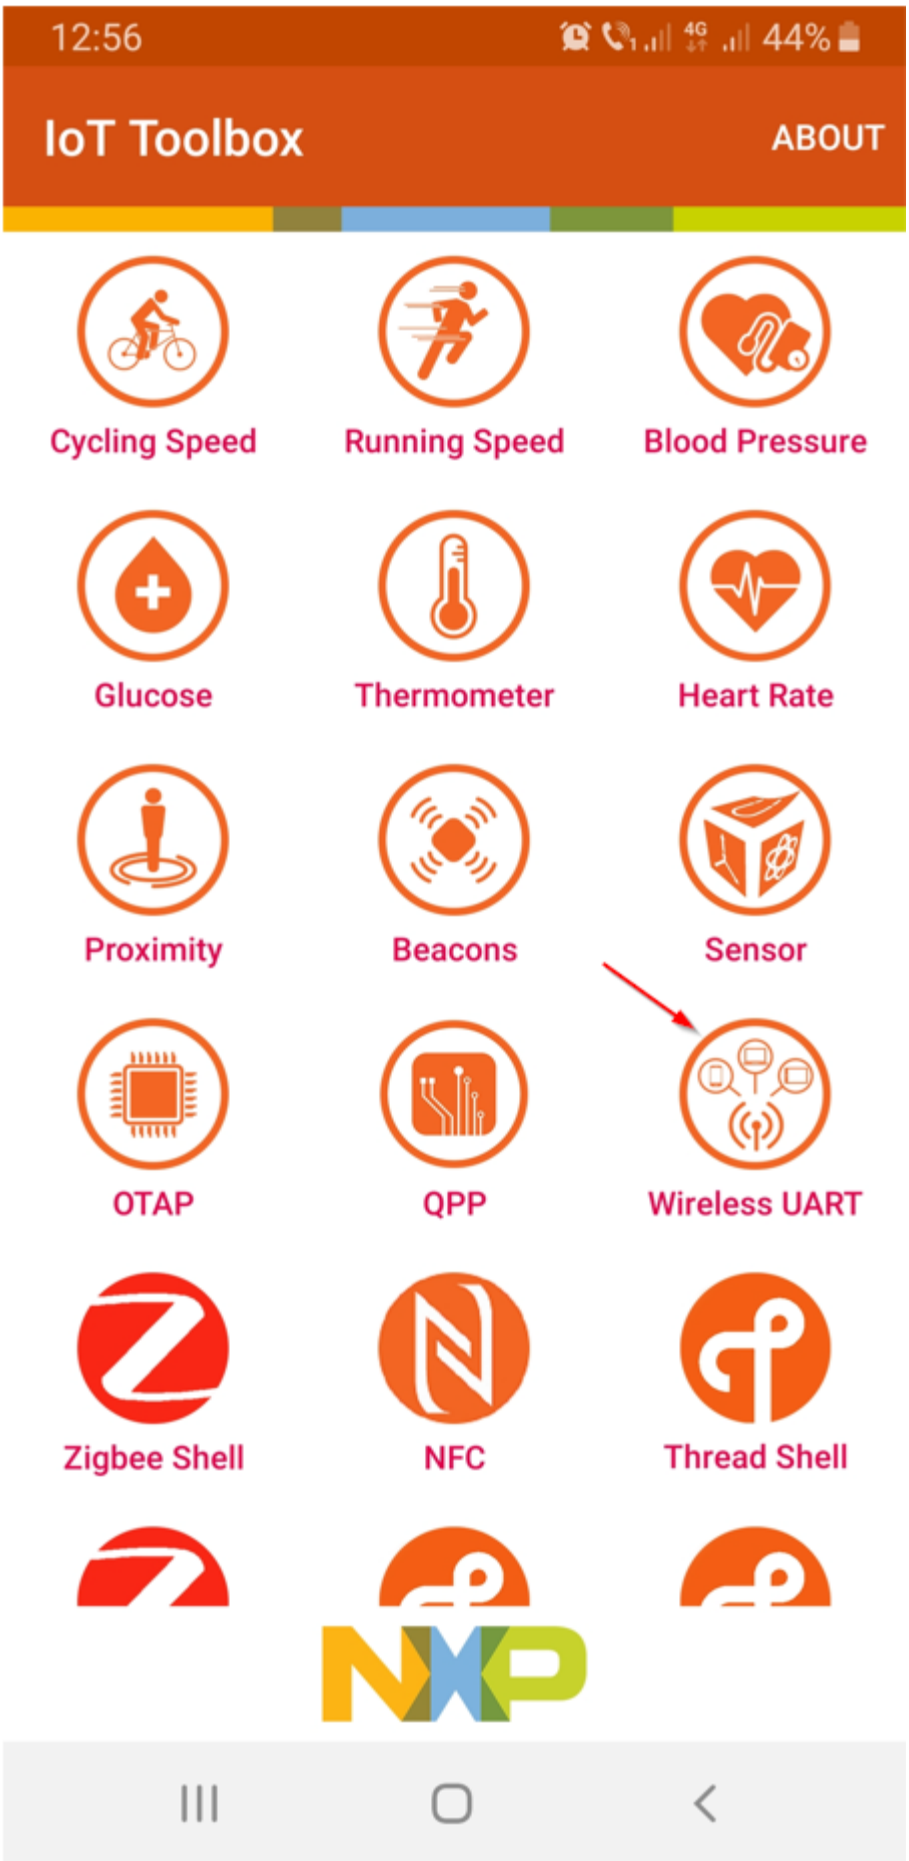
1. Flash the board with the Wireless UART application as previously described.
2. Open Tera Term (or any other Serial Communication software) and choose **Serial**. Then choose the port of your board and click **OK**.

   Setting up a new Tera Term connection for Wireless UART application



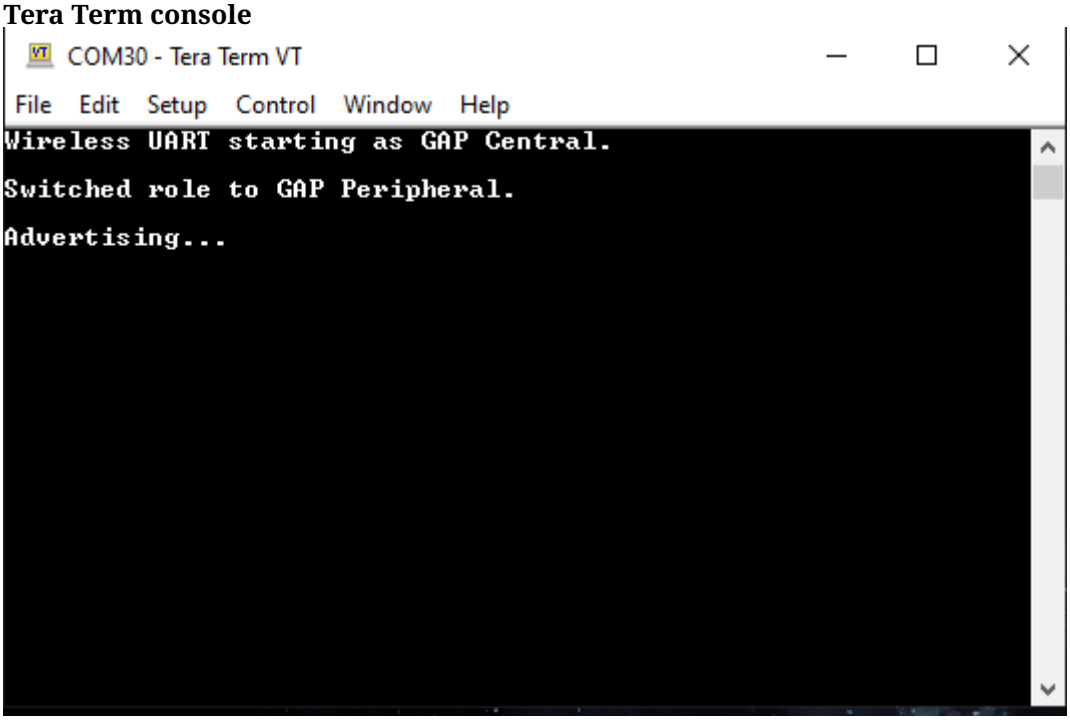
3. Stop running the code on the board. Go to **Setup** >**Serial Port**.

   Setting the serial port



4. Choose the required Speed (baud rate) and Flow Control values. Here, the baud rate should be 115200 and the Flow control mode should be set to **Xon/Xoff**.

   Setting the baud rate



5. Ensure that the Bluetooth device of your phone is enabled.
6. Open the *IoT Toolbox* application and select the ***Wireless UART*** icon.

   NXP IoT Toolbox application

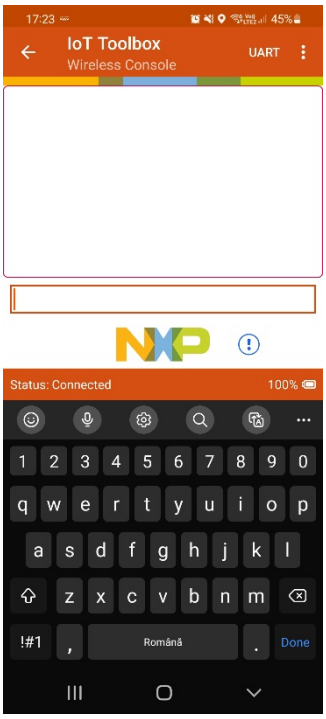
NFC
Thread Shell

7. Now run the application on the board. On this step, the RGB LED blinks white quickly. Press the button **SW3** to switch to Peripheral (Central) mode, then press **SW2** to start Advertising (scanning). The Tera Term terminal shows the message shown in the figure below.

Tera Term console

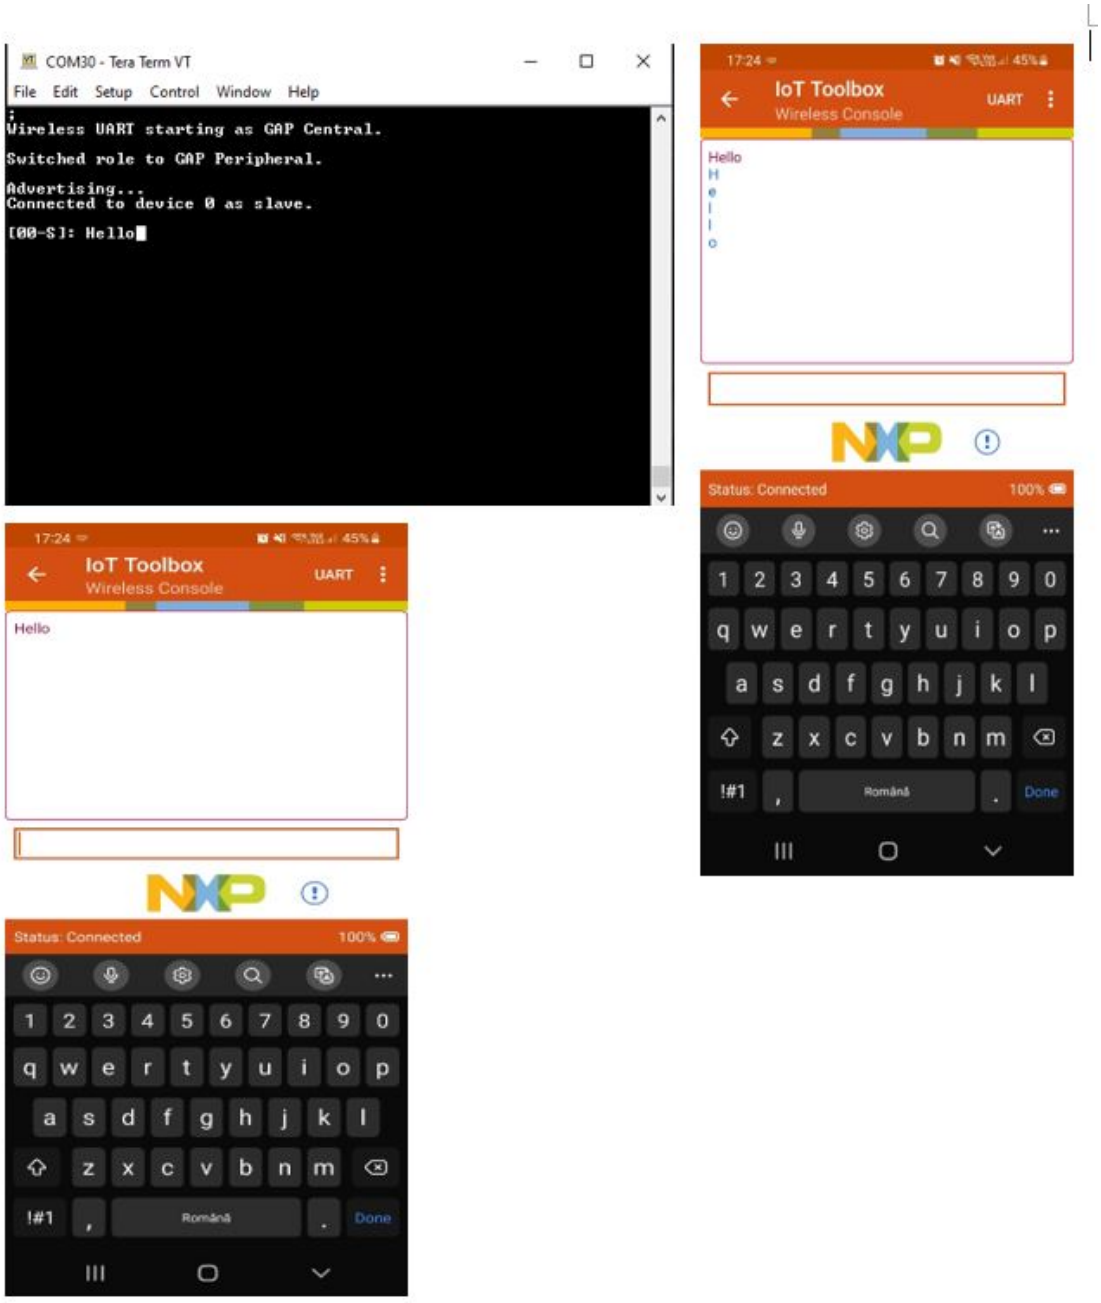


8. The device should become visible for the Wireless UART mobile application.

NXP Wireless UART scanned by IoT toolbox app

9. Select the device that appears in the **Wireless UART** tab to connect to it. After connecting, the mobile application shows the console, as shown below. Users can choose between the Wireless Console and Wireless UART tabs.

   The device should become visible for the Wireless UART mobile application.



Wireless UART working in Connected mode

10. On the IoT Toolbox Wireless application console, the message is introduced in one line and sent to the peer. If Wireless UART mode is used, communication is done character by character. On Tera Term, the message received is displayed. One character at a time can be sent from Tera Term to the peer. When the mobile application receives the character, it displays it.

    The next figure shows the board acting as a peripheral, connected to a phone using IoT Toolbox in Wireless Console and Wireless UART modes.

    Exchanging messages between the phone and Wireless UART Console

References For more information, refer to the NXP website or contact your local Field Application Engineer (FAE).

Acronyms and abbreviations The following acronyms are used in this document.

Acronym	Description
Bluetooth LE	Bluetooth Low Energy
EVK	Evaluation Kit
IDE	Integrated Design Environment
ISP	In-system Programming
IoT	Internet of Things
RTOS	Real-time Operating System
SDK	Software Development Kit
UART	Universal Asynchronous Receiver Transmitter
USB	Universal Serial Bus

Bluetooth Low Energy Demo Applications User Guide

Introduction This document describes the Bluetooth Low Energy host stack enablement for NXP development platforms. The document is organized as follows:

- *Bluetooth Low Energy applications* lists the demo applications that can be located in the Software Development Kit (SDK).
- *Hardware configurations* describes the hardware and toolchain requirements.
- *Building and running a Bluetooth LE example application* describes the general requirements for using and testing a Bluetooth Application on a compatible device.
- *Bluetooth LE stack and demo applications* describes the steps and instructions for using the demo applications on your device. It also presents the profiles and services implemented and how to interact with them.
- *References* lists the additional documents that can be referred for more information.
- *Acronyms* lists the acronyms used in this document.

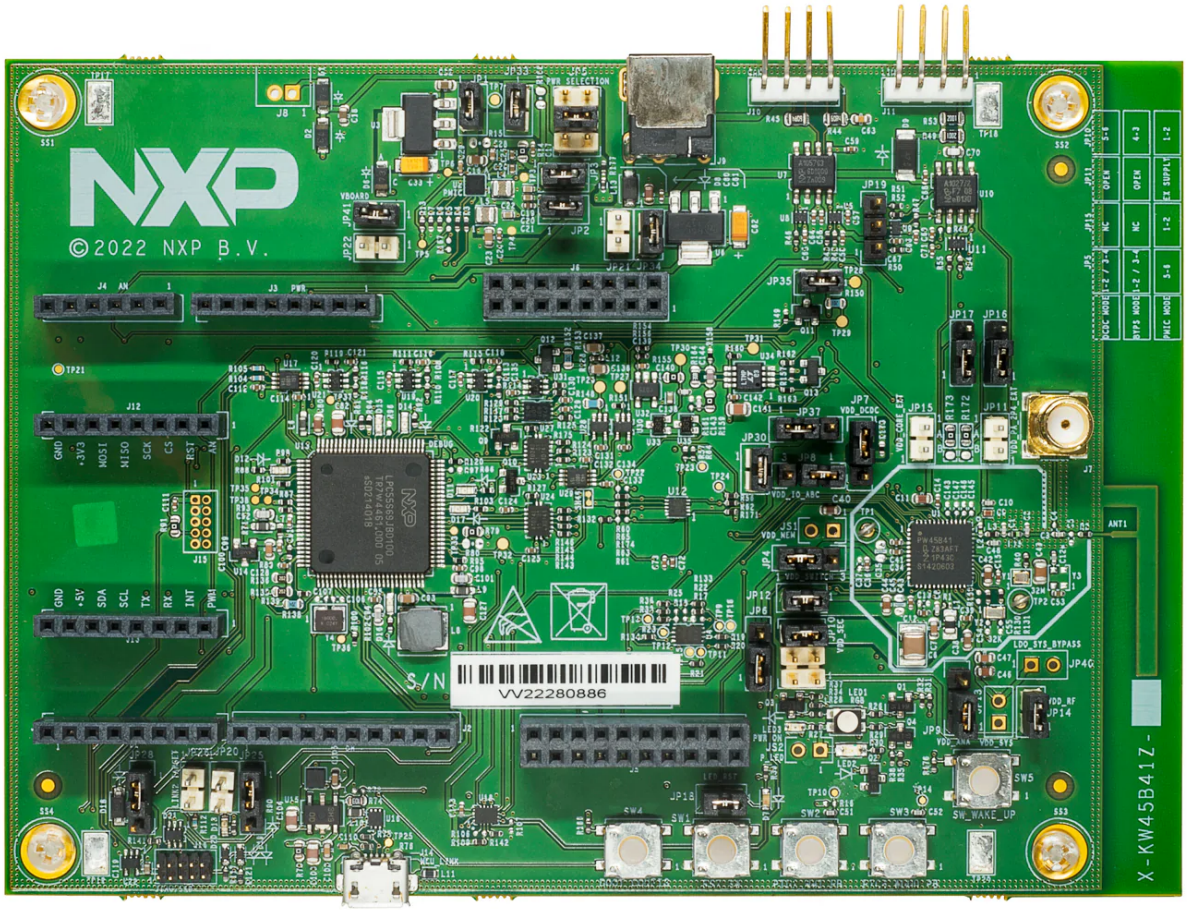
Bluetooth Low Energy applications The Software Development Package provides a Bluetooth Low Energy v5.3-compliant host stack implementation with a set of GATT-based profiles and services implemented on top. To demonstrate the device functionality, the following demo applications are implemented.

1. ANCS Client
2. Beacon Application
3. Bluetooth LE FSCI Black Box
4. EATT Central
5. EATT Peripheral
6. HCI Black Box
7. HID Host
8. HID Device (Mouse)
9. Low-power Temperature Sensor and Collector
10. Low-power Extended Advertising Central and Peripheral
11. OTAP Clients ATT and L2CAP and OTAP Server
12. Wireless UART demo application
13. Bluetooth LE Shell application
14. Hybrid (Dual-Mode) Bluetooth Low Energy and Generic FSK
15. Wireless UART Host
16. FSCI Bridge
17. NCP FSCI Black Box

Note: Refer to the application notes that are located in the 'documentation' folder.

Hardware configurations

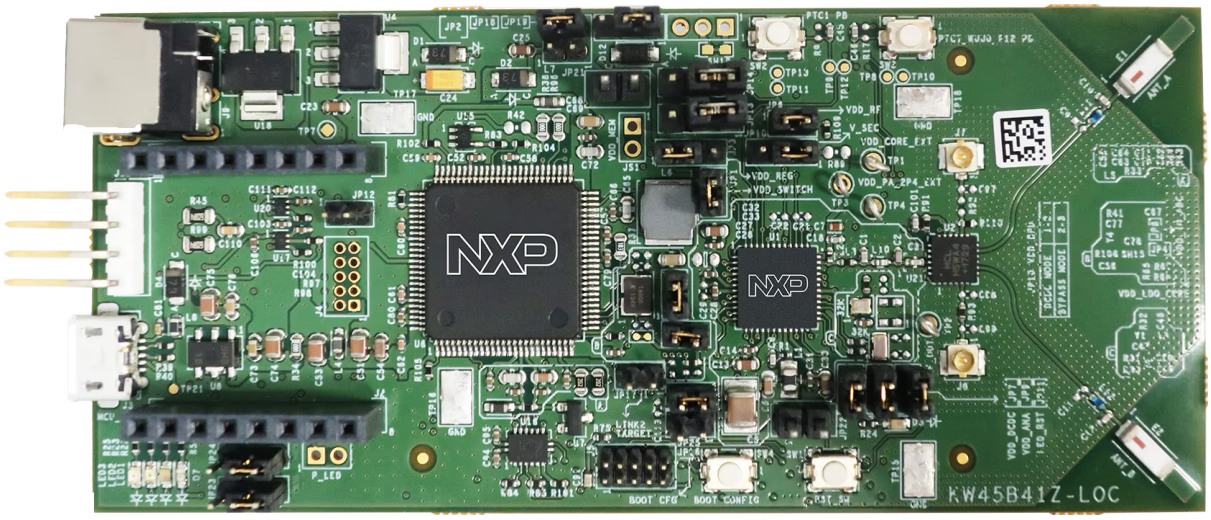
Hardware requirements The NXP Bluetooth LE demo applications run on a selection of the following platforms:



- KW45B41Z-EVK
- KW45B41Z-LOC
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- KW47-LOC
- FRDM-MCXW72
- MCX-W72-EVK
- MCXW72-LOC
- FRDM-MCXW23
- MCXW23-EVK

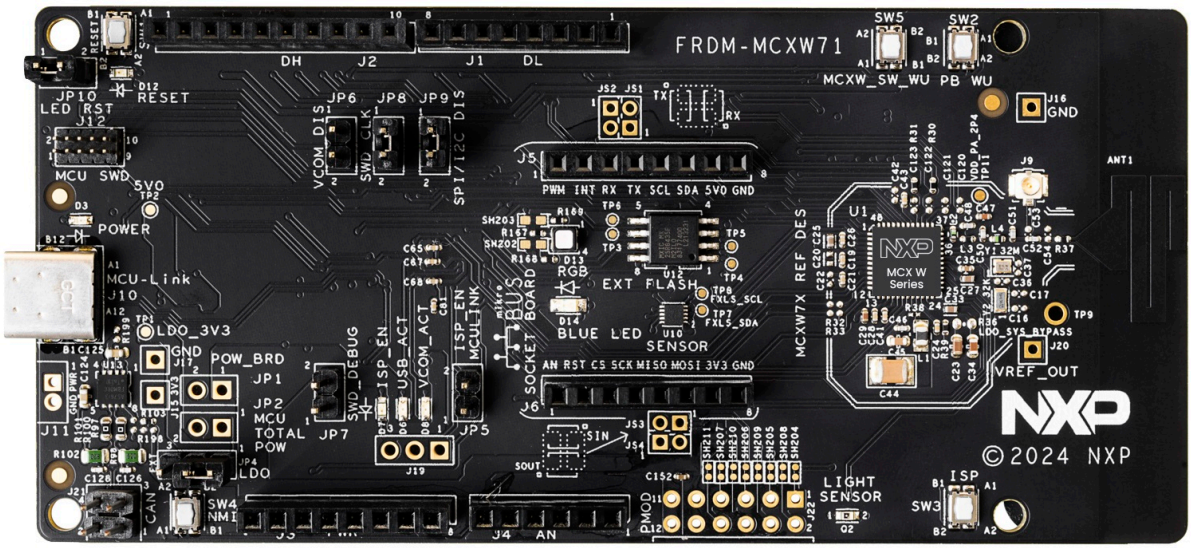
Parent topic:*Hardware configurations*

Toolchain requirements The Bluetooth Low Energy Stack demo applications were compiled and tested with IAR Embedded Workbench for Arm and MCUXpresso. Users must use one of these tools.



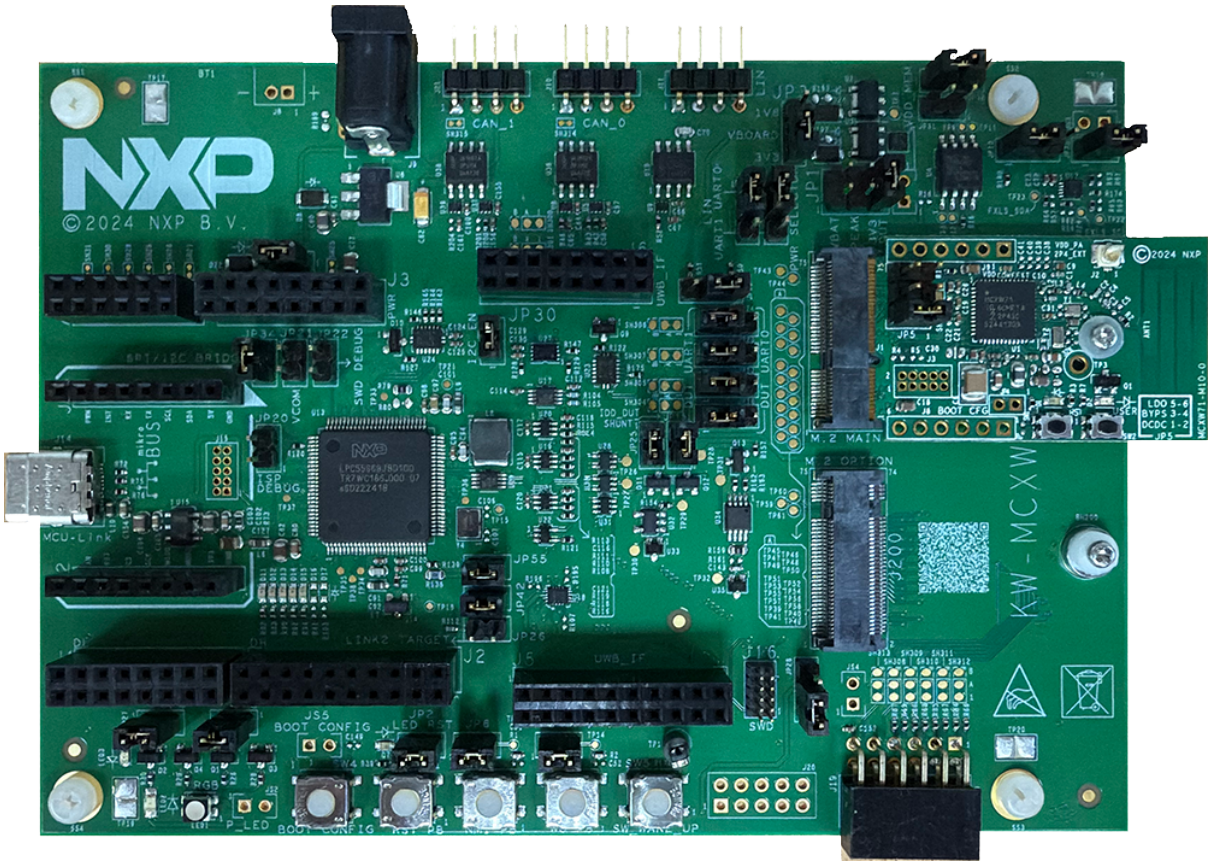
Parent topic:*Hardware configurations*

KW45B41Z-EVK platform The figure below displays the top view of the KW45B41Z-EVK board.



Parent topic:*Hardware configurations*

KW45B41Z-LOC platform The figure below displays the top view of the KW45B41Z-LOC board.



Parent topic:*Hardware configurations*

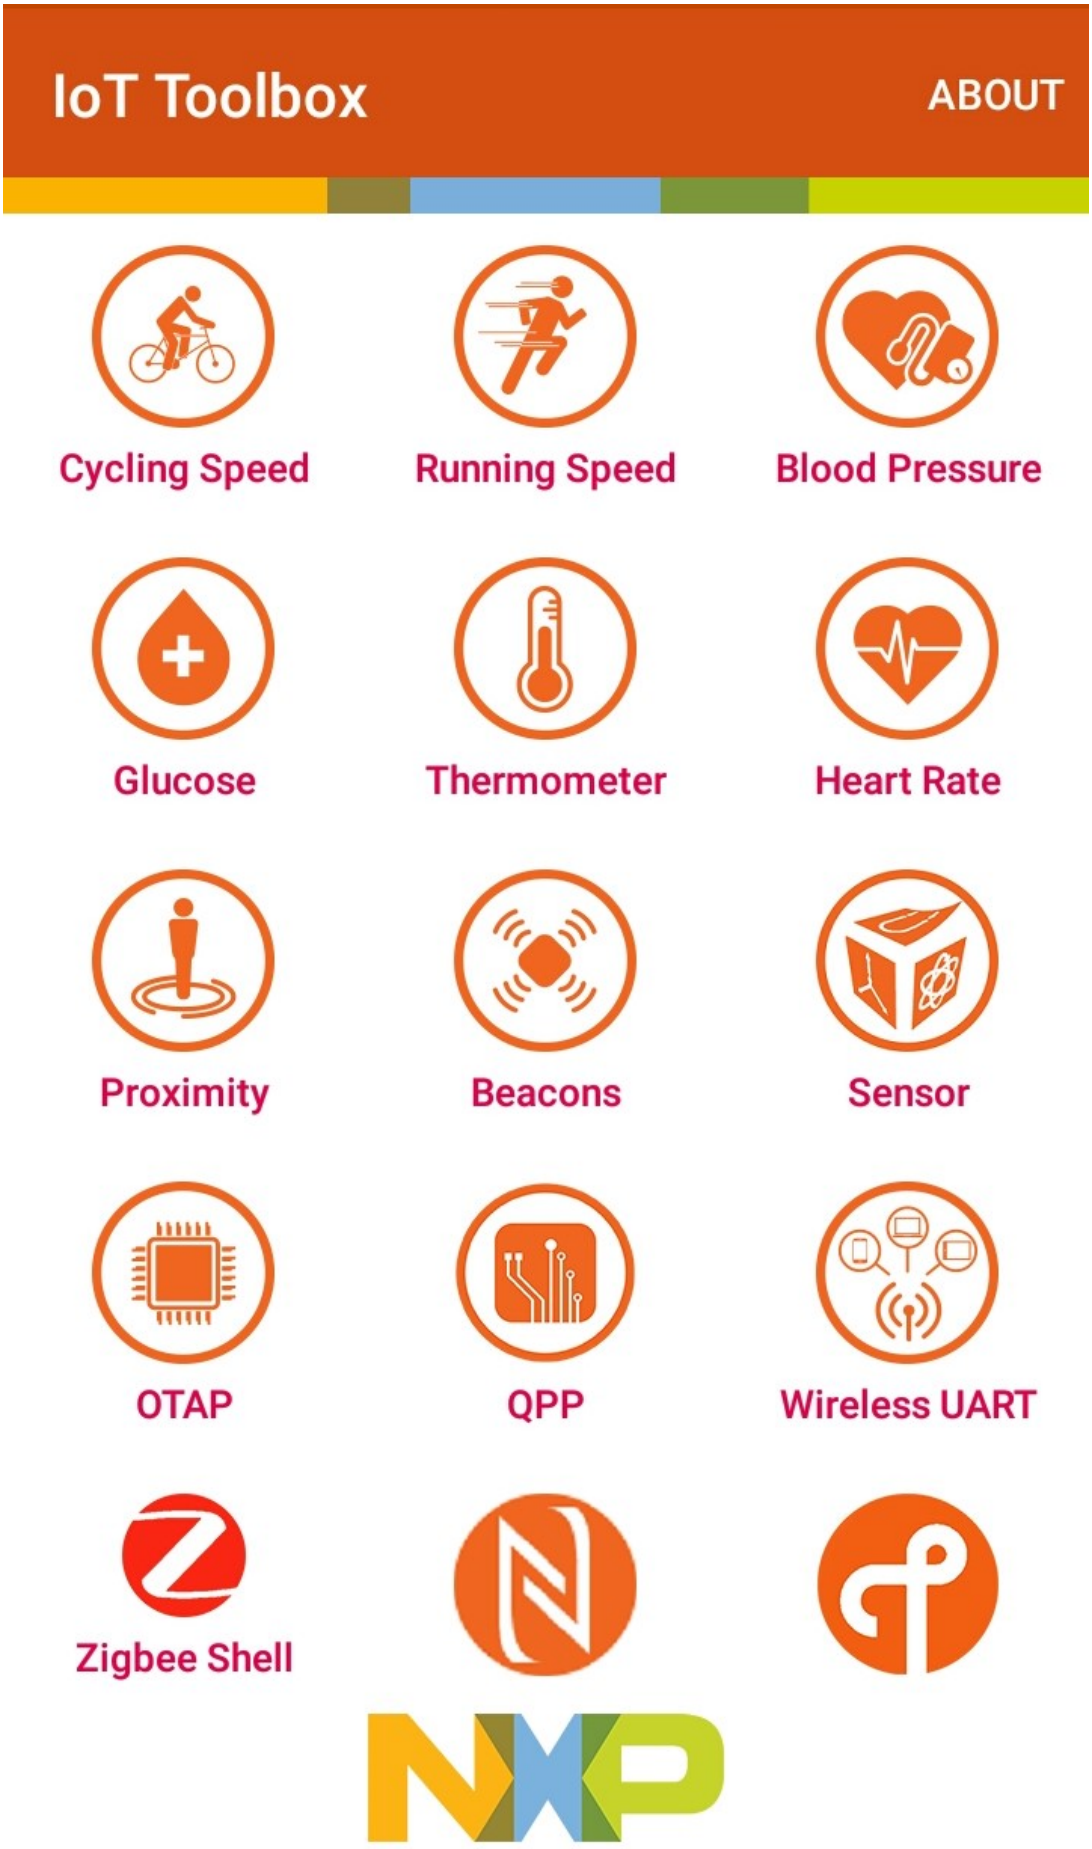
Building and running a Bluetooth LE example application This section presents the general requirements for using and testing a demo application. To open, build, and run any example application on a specific board, refer to the Bluetooth Low Energy Quick Start Guide document for the corresponding board.

User interface The demo applications that implement the Battery Service expose the current battery level, as measured on the board, through the Battery Level characteristic. The value represents a percentage between 0 and 100. The value can be read from the device from a connected GATT client.



The demo applications that implement the Device Information Service display various information regarding the current software, hardware, and firmware revisions. These values are used as an example and application developers can modify them when developing their product. The values can be read from the device through a connected GATT client.

Parent topic:*Building and running a Bluetooth LE example application*

Security The examples that enable pairing always generate a default passkey of 999999 that must be entered on the Central device, which is usually a smartphone or tablet.

Parent topic:*Building and running a Bluetooth LE example application*

Testing devices To demonstrate the profile functionality, most of the scenarios require one of the supported platforms and a Bluetooth Low Energy capable central device. The device is usually a smartphone or a tablet that runs a compatible Bluetooth LE application. The figure below shows the **IoT Toolbox** UI.

IoT Toolbox
ABOUT
Cycling Speed
Running Speed
Blood Pressure
Glucose
Thermometer
Heart Rate
Proximity
Beacons
Sensor

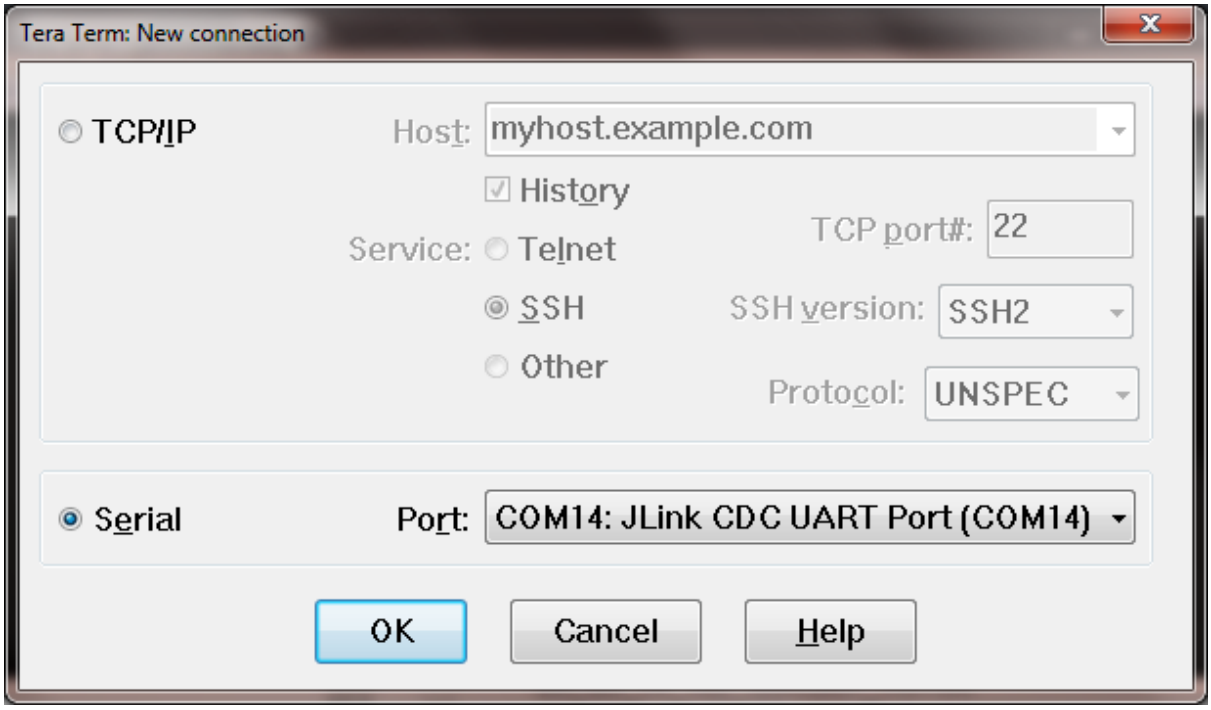
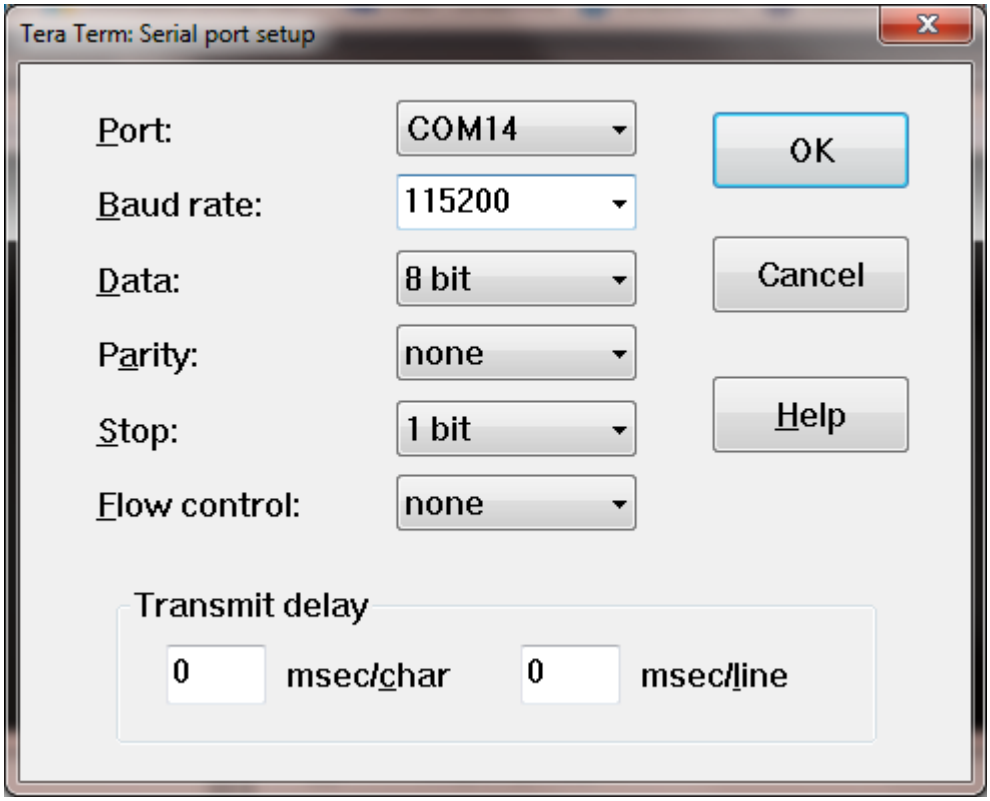
QPP
Wireless UART
Zigbee Shell
NXP



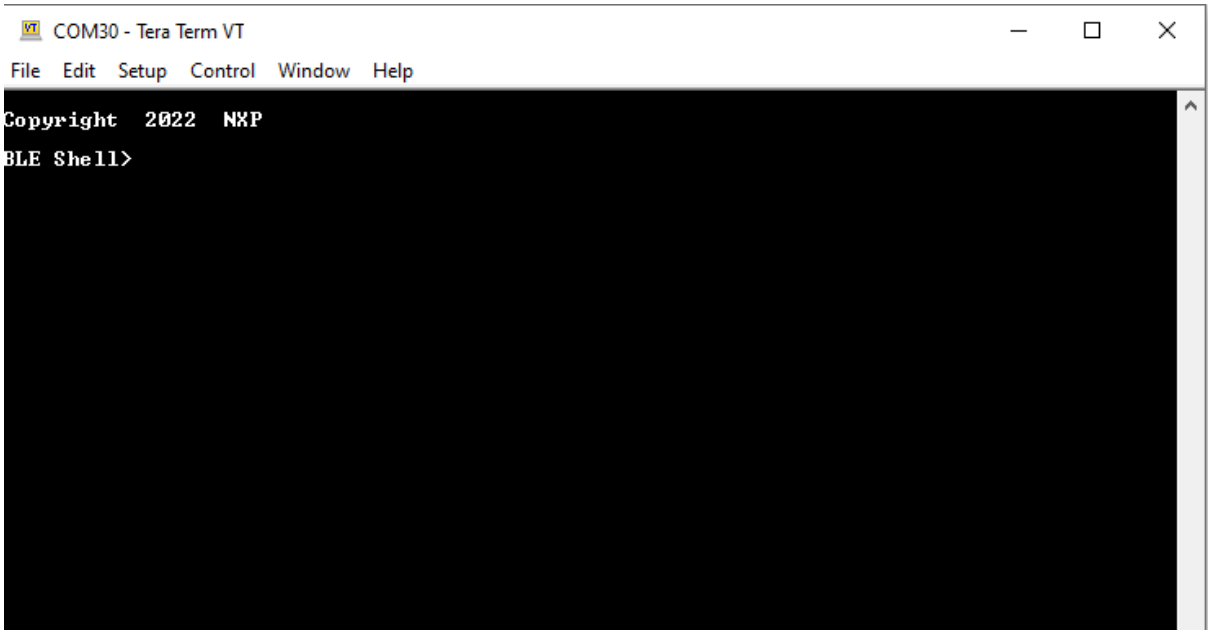
IOT toolbox

The recommended application is the IoT Toolbox, which can be installed on Apple iOS or Android OS handheld devices that support Bluetooth Low Energy. The application can be found on Apple Playstore or on Google Play.



Other demos can be run by using two platforms, one for the peripheral and one for the central role. A few examples of such demos are listed below:

- Low-Power Temperature Sensor and Collector
- Wireless UART
- OTAP Client and Server
- HID Host and Device
- Extended Advertising Central and Peripheral
- EATT Central and Peripheral



To provide feedback and more interaction, some examples use a shell console via the virtual COM port. To access the device, open a serial port terminal and as shown in the figure below. For this example, Tera Term VT and a KW45B41Z-EVK or a FRDM-MCXW71 board can be used. The communication parameters are 115200 and 8N1.

Connect it to the platform with parameters as shown in the figure below .

The start screen is displayed after the board is reset as shown in the figure below .

Parent topic:*Building and running a Bluetooth LE example application*

Time client devices Some applications implement the Current Time Service. To enable this feature, define the gAppUseTimeService_d parameter in the app_preinclude.h file as 1. If the Time Client is enabled, the device must synchronize with a Time Server to update its internal date/time to the current date/time. If you connect the device to the phone, the Time Client synchronizes with the phone (pairing and bonding must be active).

Parent topic:*Building and running a Bluetooth LE example application*

Bluetooth LE stack and demo applications

ANCS/AMS client (ancs_c) This section describes the implemented profiles, services, user interactions, and testing methods for the ANCS and AMS Client application.

Implemented profile and services The ANCS/AMS Client application implements both an ANCS and an AMS Client for the custom ANCS Service and AMS Service available on iOS mobile devices.

Check the documentation available on the iOS website for details about the ANCS or AMS services, their characteristics, and supported features.

The demo application acts as a GAP Peripheral that advertises a service solicitation for the custom ANCS Service, followed by a solicitation to the AMS Service. It also acts as a GATT Client once connected to a device that offers the ANCS/AMS Service. The application offers some services such as the role of GATT Server.

Once connected to a mobile device offering the ANCS/AMS Service, the application displays information about ANCS Notifications received from that device. This information is followed by the AMS track information (Artist, Album, Title, Duration in seconds). The application also displays the possible remote commands that the device state allows (such as Play, Pause, VolumeUp, VolumeDown). The notifications are received via ATT Notifications, for which the ANCS Client must register on the peer ANCS Server. The same must be done for the AMS server. It initially configures the information that it wants to be notified about. The application also retrieves and displays additional information about the received ANCS notifications. For this purpose, it writes commands to specified characteristics on the ANCS/AMS Server and receives responses via ATT Notifications from other characteristics. All information is displayed to the user using a shell available over a serial communications interface.

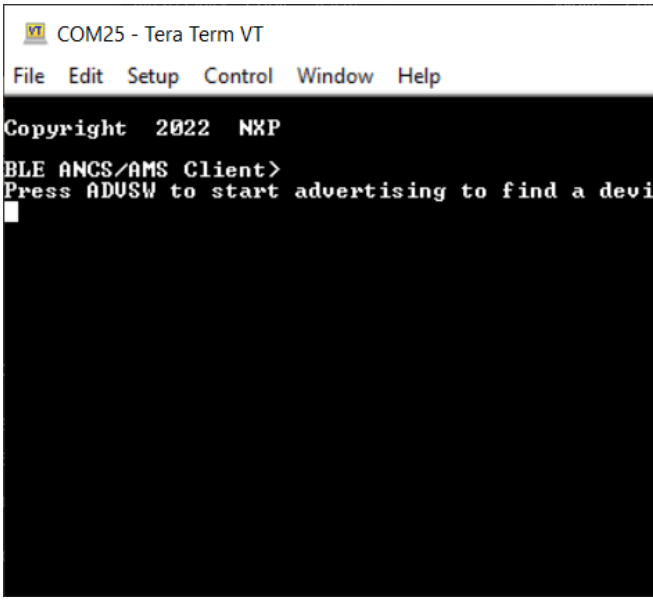
Accessing the ANCS Service and AMS Service requires Bluetooth LE security to be enabled.

Parent topic:ANCS/AMS client (ancs_c)

Supported platforms The ANCS/AMS Client application is supported on the following platform:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK

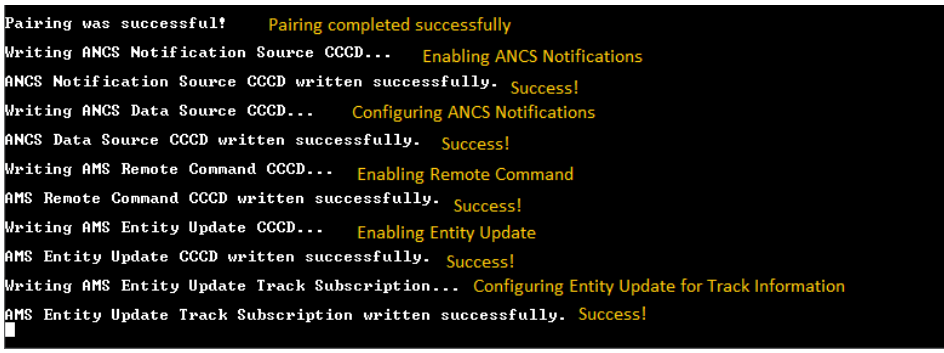
Parent topic:ANCS/AMS client (ancs_c)



User interface After flashing the board, the device is in idle mode (all LEDs flashing). To start advertising, press the **ADVSW** button. When in GAP Discoverable Mode, **CONNLED** is flashing. When the ANCS/AMS Server (Gap Central) connects to the ANCS/AMS Client (GAP Peripheral), **CONNLED** turns solid. To disconnect, hold the **ADVSW** for 2-3 seconds. The ANCS/AMS Client then re-enters the advertising state.

For displaying operating information and ANCS Notifications (AMS information and commands), the demo application uses a shell exposed via a serial communication interface.

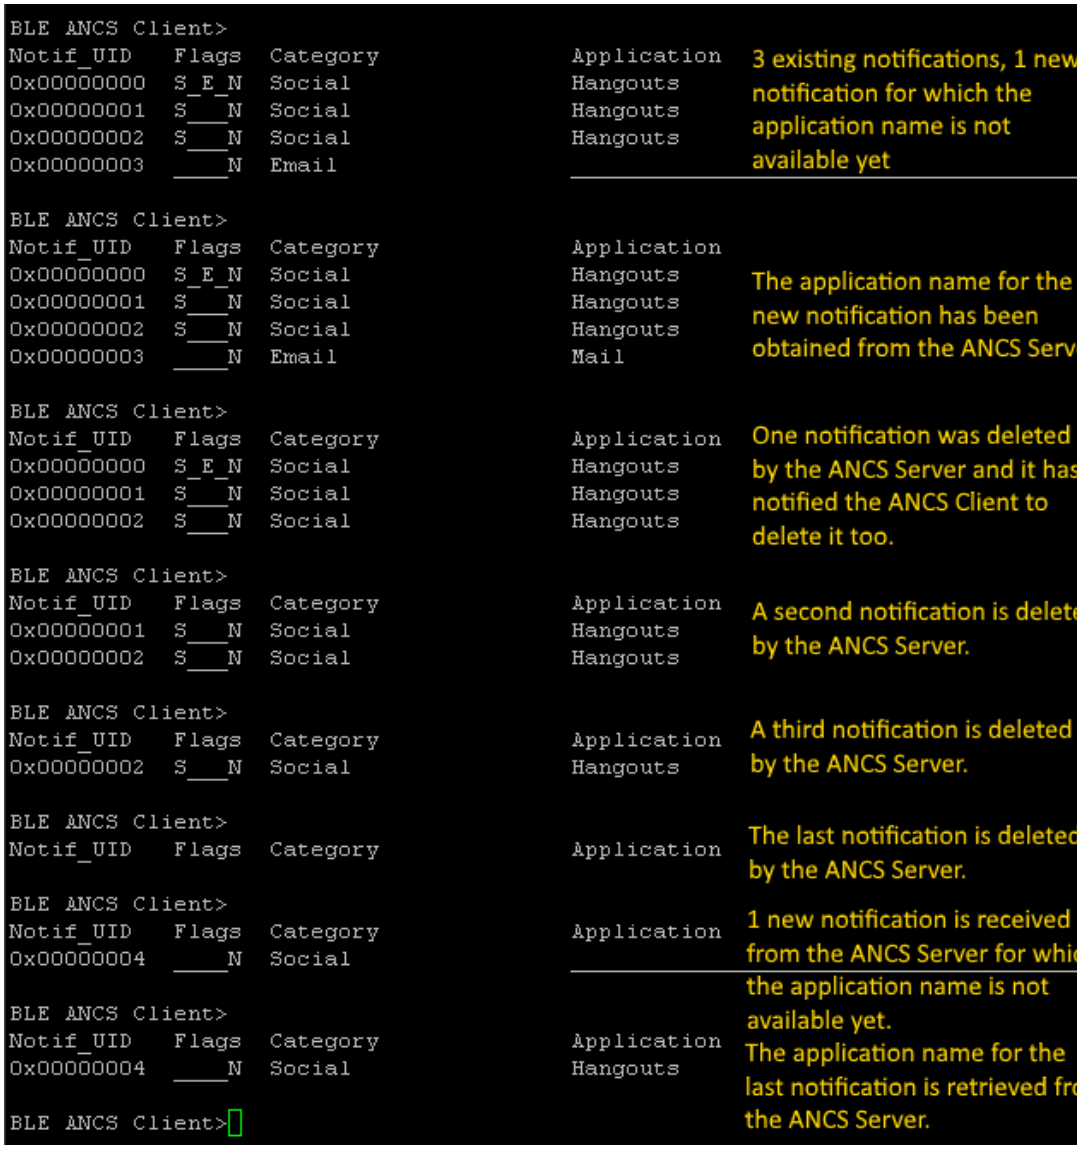
Parent topic:ANCS/AMS client (ancs_c)



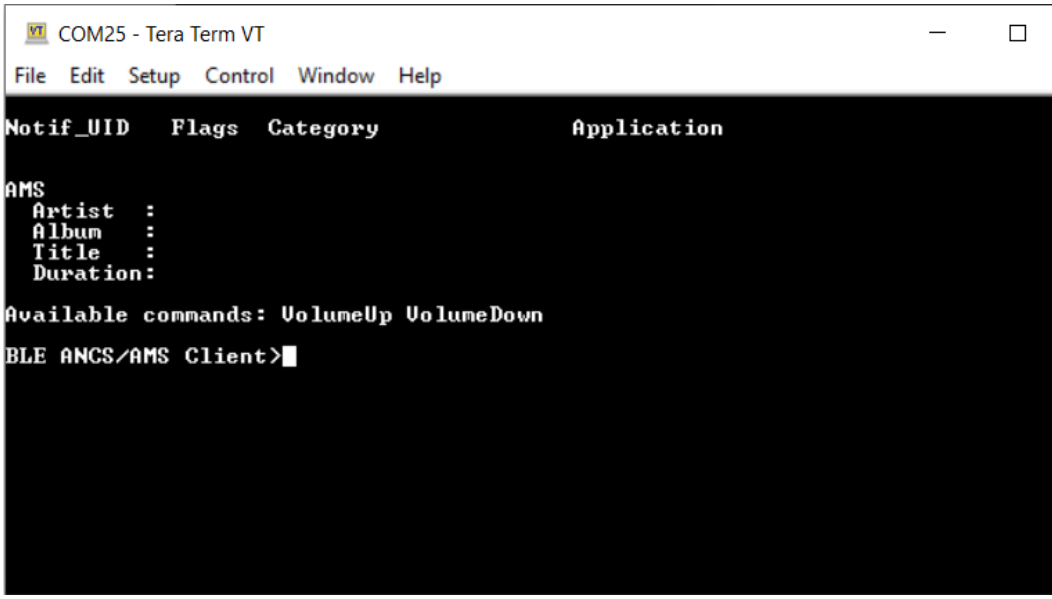
Usage The ANCS/AMS Client demo application is designed to work with a peer mobile device that exposes the ANCS and AMS service. Also, a serial terminal application is required for displaying ANCS Notifications information and AMS commands and information.

1. Open a serial terminal application on the PC and connect it to the serial port corresponding to the board on which the ANCS/AMS Client runs. See the details in Testing devices, "User Interface". A start screen is displayed immediately after the board is reset. All LEDs must be flashing as shown in the figure below.

Start screen for ANCS/AMS Client demo application



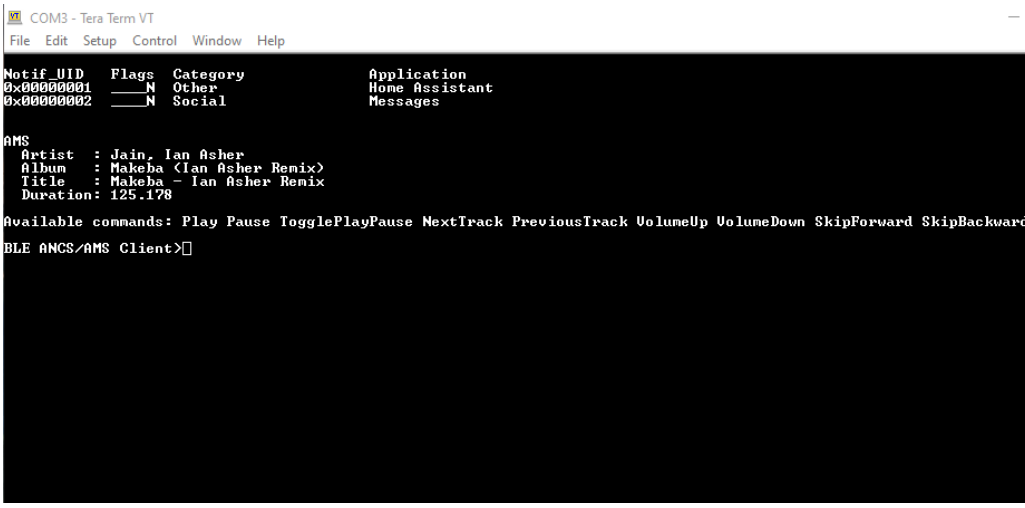
2. Press the **ADVSW** button to start advertising. This instruction is also displayed in the serial terminal as shown in the figure above.
3. The peer device starts scanning for Bluetooth LE devices and connects to the ANCS/AMS Client device that is advertising.
4. Once connected to a peer, the application looks for the ANCS Service and AMS Service and their characteristics. If they are found, the ANCS Client tries to register for receiving notifications and AMS for the tracking data and commands. See Figure.
5. If any security-related ATT errors are encountered, then the application automatically performs Pairing and Bonding and retries the failed ATT operations. Depending on the negotiated pairing method, user interaction might be needed to complete the Pairing. Follow the onscreen instructions provided by both the ANCS/AMS Client and the mobile device. If the ANCS/AMS Client generates a passkey, then the default 999999 passkey is used. See the figure below that shows a 'Pairing is successful' message.



Pairing is successful message

6. After bidirectional communication is established via GATT, the ANCS/AMS Client starts displaying ANCS Notifications information as shown in the figure below.

ANCS Notifications



- The combination of the two services (ANCS and AMS) is shown in the two figures below.
- If no media is playing and no player is active, the serial interface looks as shown in the figure below.

AMS no active player

- When media is playing, a player is active and the state must look similar to the figure below.

AMS with player active

Parent topic:ANCS/AMS client (ancs_c)

Parent topic:*Bluetooth LE stack and demo applications*

Beacon This section presents the user interactions and testing methods for the Beacon application.

Advertising data The beacons are non-connectable advertising packets that are sent on the three advertising channels. The latter contains the following fields.

- Company Identifier (2 bytes): 0x0025 (NXP ID as defined by the Bluetooth SIG).
- Beacon Identifier (1 byte): 0xBC (Allows identifying an NXP Beacon alongside with Company Identifier).
- UUID (16 bytes): Beacon sensor unique identifier.
- A (2 bytes): Beacon application data.
- B (2 bytes): Beacon application data.
- C (2 bytes): Beacon application data.

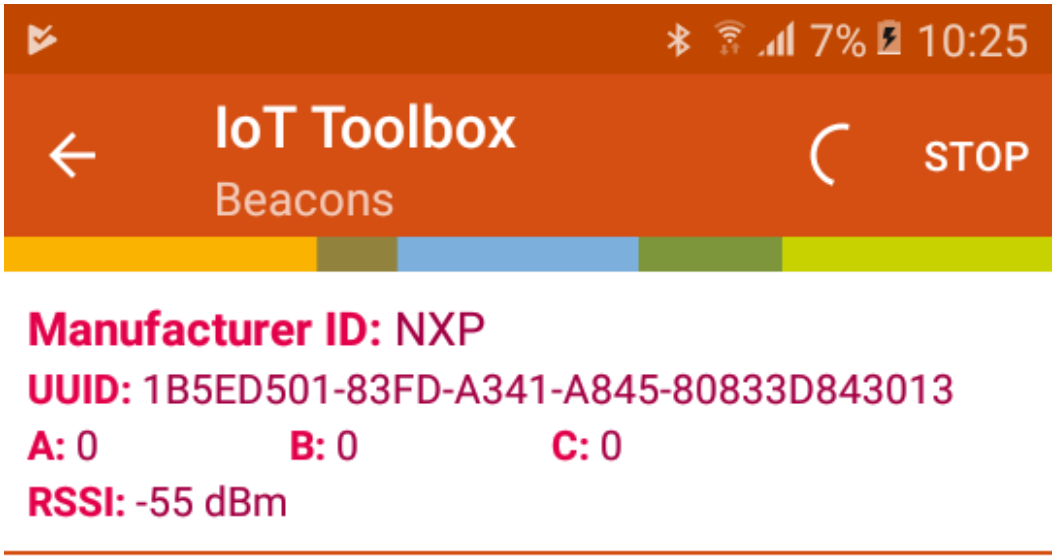
- RSSI at 1m (1 byte): Allows distance-based applications.

By default, the UUID value is a random value based on the unique identifier of the board.

Parent topic: Beacon

Supported platforms The following platforms support the Beacon application:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK



Parent topic: Beacon

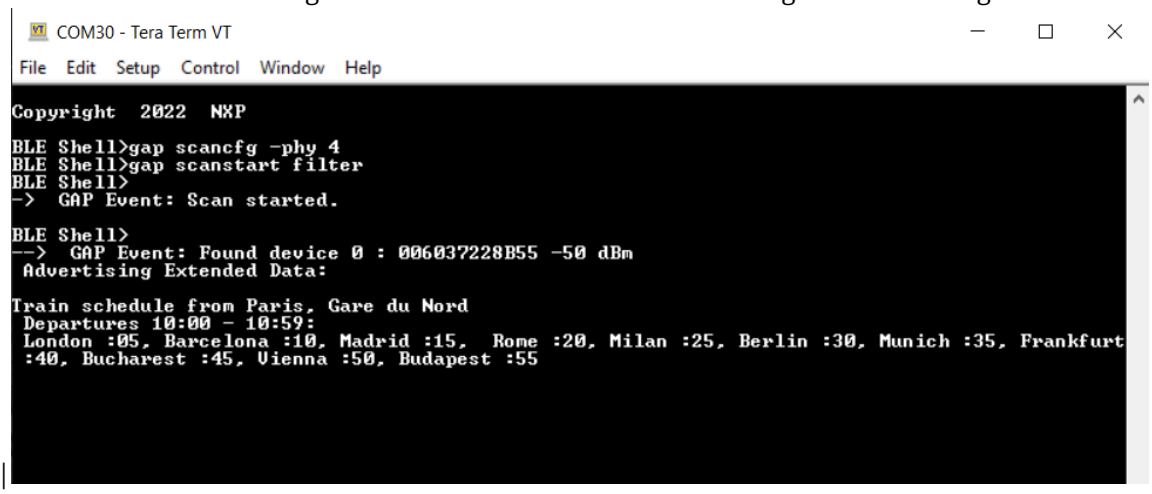
User interface After flashing the beacon, the sensor is put in deep sleep (all LEDs are off). To flash the board in case the beacon is put in Deep-sleep mode, press the **ADVSW** or **RESET** button. After this step, any attached debugger loses its connection. The default configuration of the application enables low power, which disables LED support. The user can manually change the configuration and enable LED support, otherwise all subsequent LED behavior references are ignored.

By default, the application uses extended advertising. However, it can be configured to use legacy advertising by setting the $\mathrm{gBeaconAE_c}$ define to 0. In the legacy configuration, the first press of the advertising switch starts the legacy advertising and the second press stops it.

Parent topic: Beacon

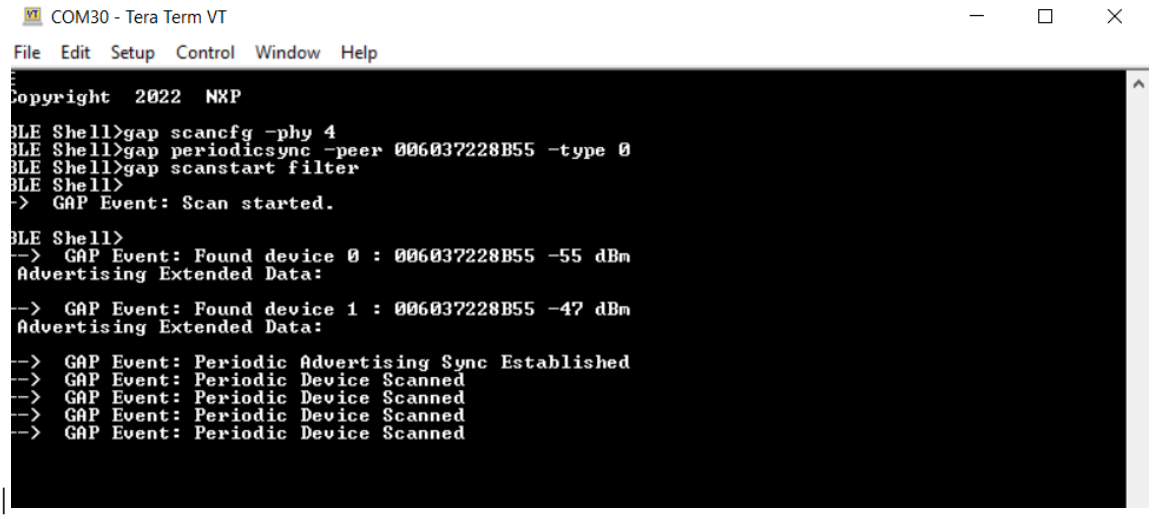
Usage The beacon can be tested with any Bluetooth® Smart Ready products available on the market. The IoT Toolbox can also be used to showcase the profile functionality, as shown in the figure **IoT Toolbox Beacon Demo** below.

7% 10:25
IoT Toolbox
Beacons
STOP
Manufacturer ID: NXP
UUID: 1B5ED501-83FD-A341-A845-80833D843013
A: 0
B: 0
C: 0
RSSI: -55 dBm



Parent topic: Beacon

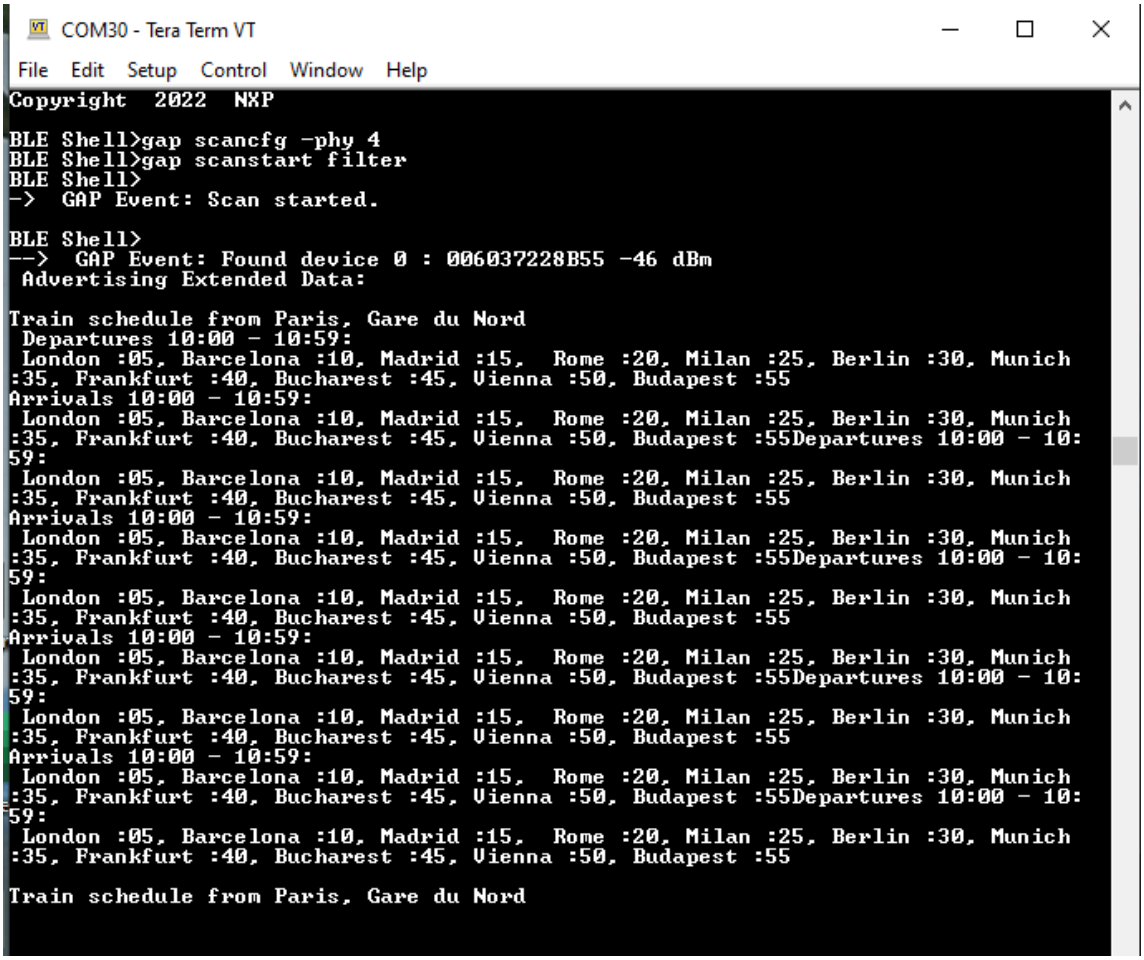
Beacon usage with extended advertising To use the Beacon application with the advertising extensions capabilities, the gBeaconAE_c define option must be set to 1. Doing this enables the usage of extended advertising and periodic advertising. The application cycles between these modes are in the following manner:



- The first **ADVSW** press starts legacy advertising, **CONNLED** turns solid.
- The second **ADVSW** press stops legacy advertising and starts extended advertising, **CONNLED** turns off, **EXTADVLED** turns solid.
- The third **ADVSW** press stops extended advertising carrying data and then starts extended advertising without data and periodic advertising, **EXTADVLED** starts flashing.
- The fourth **ADVSW** press stops periodic advertising and extended advertising without data and starts legacy advertising and extended advertising, both **CONNLED** and **EXTADVLED** turn solid.
- The fifth ADVSW press stops them all, both **CONNLED** and **EXTADVLED** turn off.

Not all smartphones support extended advertising, hence a different method to view the AE beacon is to use the ble_shell application. In order to do this, perform the following steps:

1. Flash a board with the beacon application, as described above.
2. Flash a board with the ble_shell application, as described in Bluetooth LE Shell and connect to it using a serial port.
3. Press the **ADVSW** button two times on the beacon to start extended advertising on the coded PHY.
4. To view the advertising data, enter the following commands in the shell terminal to set the scanning PHY to coded and start scanning. See the figure below.



5. To start the periodic advertising, press **ADVSW** button again on the beacon.
6. To sync with the beacon, issue the following commands on the shell terminal as shown in the figure below.

The peer parameter of the periodicsync command is the public address of the beacon.

Extended Advertising with very large data To use very large advertising data for extended advertising, set the gBeaconLargeExtAdvData_c define to 1. The same steps are used to view the data using ble_shell :

1. Flash a board with the beacon application.
2. Flash a board with the ble_shell application, as described in Bluetooth LE Shell and connect to it using a serial port.
3. Press the **ADVSW** button two times on the beacon to start extended advertising on the coded PHY.
4. To view the advertising data, enter the following commands in the shell terminal to set the scanning PHY to coded and start scanning. See the figure below.

Parent topic: Beacon

Parent topic:*Bluetooth LE stack and demo applications*

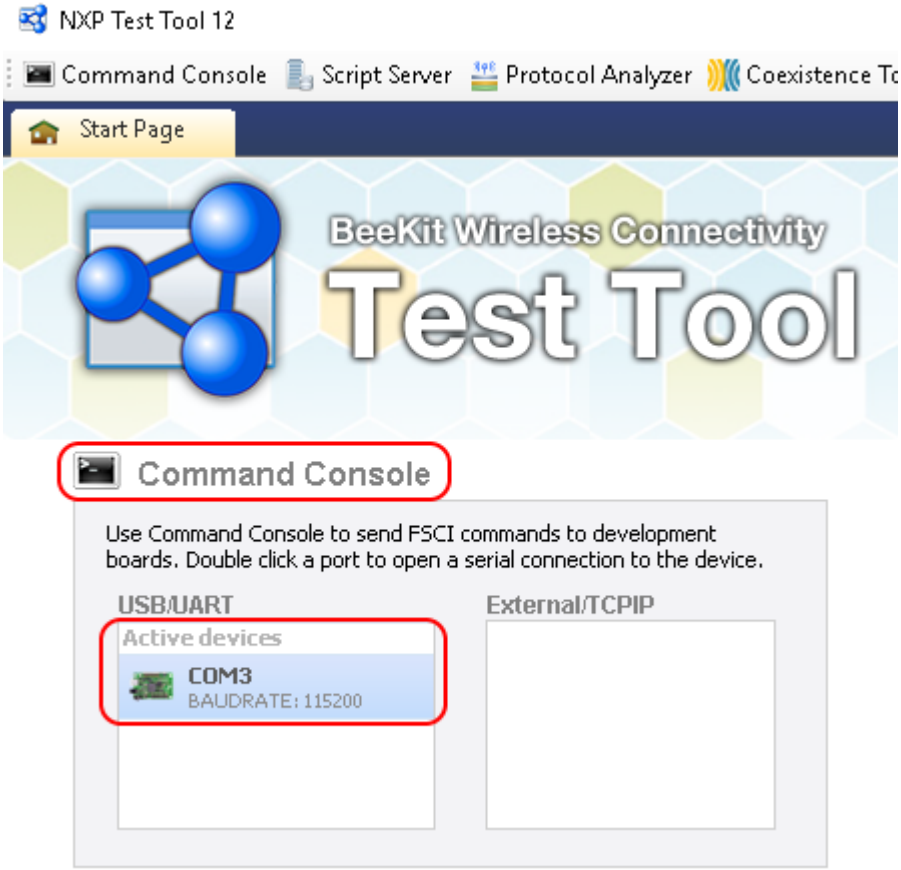
Bluetooth LE FSCI Black Box This section describes the functionality, user interactions, and testing methods for the Bluetooth LE FSCI Black Box demo application.

Description The Bluetooth LE FSCI Black Box demo application gives access to the Bluetooth LE Host Stack via a serial interface using the FSCI protocol. See the *FSCI (Framework Serial Communication Interface) manual* for the format of the FSCI commands and a full list of supported commands.

The demo can be used with the Test Tool for Connectivity Products. Command Console application can be downloaded from the NXP website or using a custom application that supports the FSCI protocol and commands.

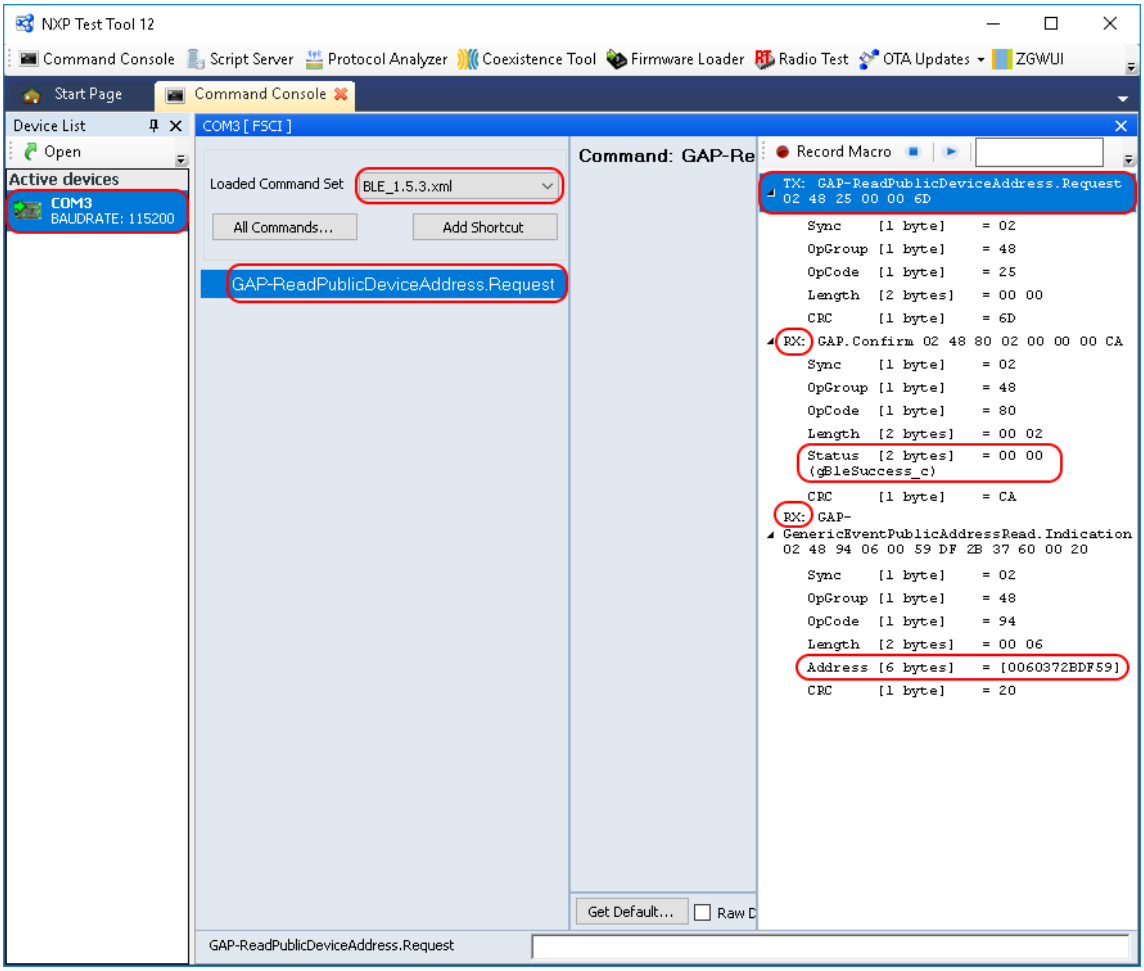
Parent topic: Bluetooth LE FSCI Black Box

Supported platforms The following platforms support Bluetooth LE FSCI Black Box application:



- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK

- FRDM-MCXW72
- MCX-W72-EVK



Parent topic: Bluetooth LE FSCI Black Box

Usage with Test Tool for connectivity products The Bluetooth LE FSCI Black Box demo application is designed to be used via serial interface. This can be done using the TEST Tool for Connectivity Products – Command Console application as described below.

1. Download the demo application onto a supported board.
2. Connect the board to a USB port of the PC. The UASB COM port drivers must be installed properly and a COM port corresponding to the board should be available.
3. Open the Test Tool application and connect to the serial port corresponding to the board on which the Bluetooth LE FSCI Black Box application runs. See Figure. The serial communication parameters are: baud rate 115200, 8N1, and no flow control.

4. Select the appropriate Test Tool XML file from the drop-down list for the release being used and send commands to the application. An example is shown in Figure.

Parent topic: Bluetooth LE FSCI Black Box

Parent topic:*Bluetooth LE stack and demo applications*

EATT Central This section describes the implemented profiles and services, user interactions, and testing methods for the EATT Central application.

Implemented profiles and services The EATT Central application implements a GATT server and the following profiles and services:

- Generic Attribute Profile

The application behaves as a GAP central node. It searches for an EATT peripheral to connect to. After connecting, it performs service discovery, initiates an EATT connection and configures indications on the peripheral for services A and B. The Central reports the received service data and the steps taken during the setup on a terminal connected to an UART port.

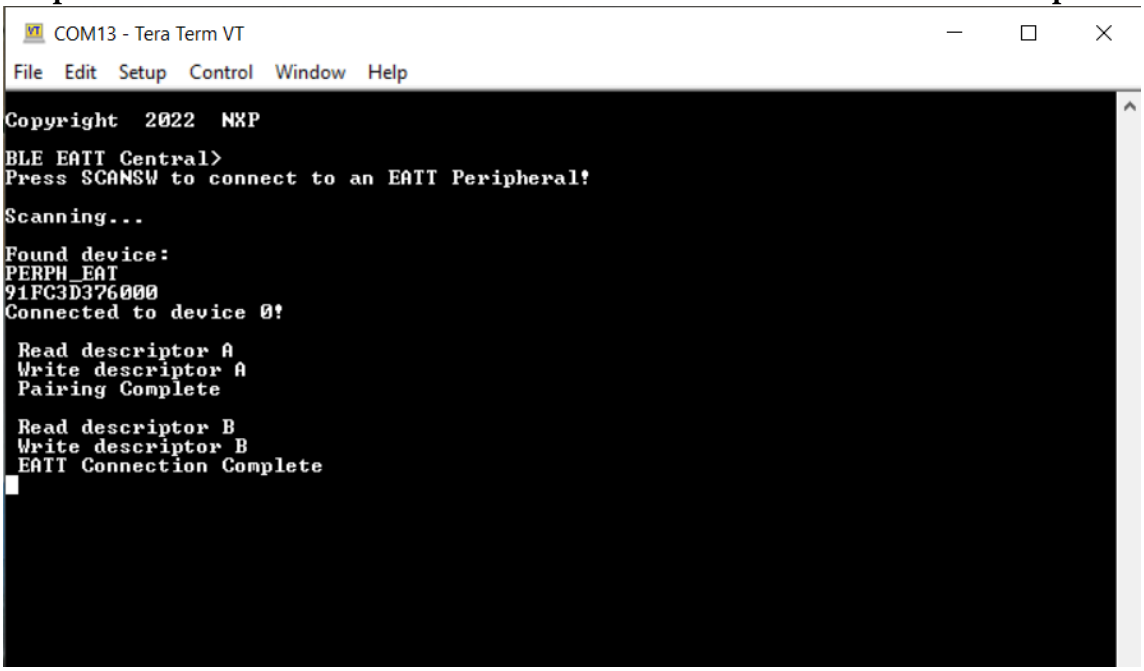
Parent topic:EATT Central

Supported platforms The EATT Central application is supported on the following platforms:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK

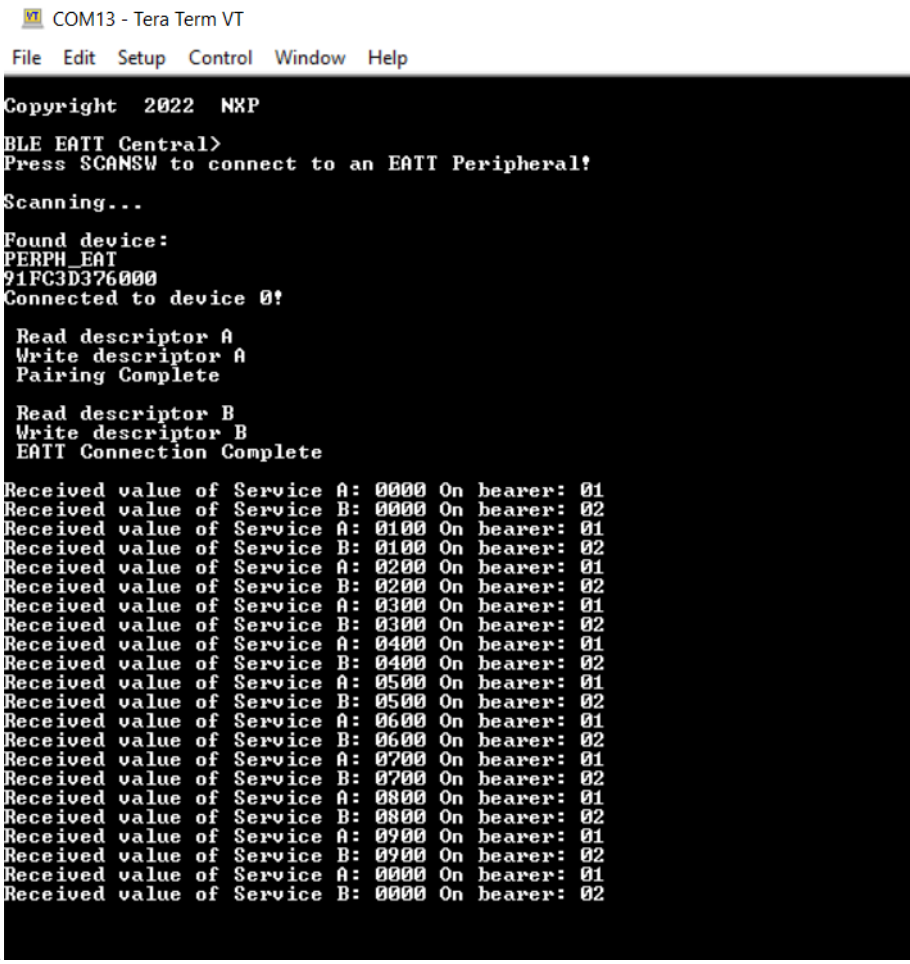
- FRDM-MCXW72
- MCX-W72-EVK

Parent topic:EATT Central



User interface After flashing the board, the central is in Idle mode (all LEDs flashing). To start scanning, press the **SCANSW** button. After connecting to the peripheral, the **CONNLED** turns solid. The data information together with the bearer it was received on is sent over UART. To disconnect the node, hold the **SCANSW** button pressed for 2-3 seconds. The node then restarts scanning.

Parent topic:EATT Central



Usage The application can be tested using another board flashed with the EATT Central application as described in the EATT Peripheral.

1. Open a serial port terminal and connect it to board, in the same manner described in Testing devices. The start screen is displayed after the board is reset.
2. To start scanning for devices, press the **SCANSW** button on the EATT Central board. To make it enter discoverable mode, perform the same step on the EATT Peripheral board. The host connects with the board after it sees it advertise the service A and service B UUIDs. After connecting, the central performs service discovery, indicates its EATT support to the server by writing the Client Supported Features characteristic, enables indications for services A and B, and then initiates an EATT connection with the server. See the figure below.

   Output console on the EATT Central connected with an EATT Peripheral

3. After the EATT connection is complete, the console displays the received data and the bearer on which it was sent, as shown in the figure below.

Output console on EATT Central

Parent topic:EATT Central

Parent topic:*Bluetooth LE stack and demo applications*

EATT Peripheral This section describes the implemented profiles and services, user interactions, and testing methods for the EATT Peripheral application.

Implemented profiles and services The EATT Peripheral application implements a GATT server and the following profiles and services:

- Battery Service v1.0
- Device Information Service v1.1
- Generic Attribute Profile

The Generic Attribute Profile includes the Server Supported Features characteristics, which is used to indicate EATT support to the peer, and the Client Supported Features characteristic, which is used by the peer to indicate its own EATT support.

The application behaves as a GAP peripheral node. It enters GAP General Discoverable Mode and waits for a GAP central node to connect. The application implements two custom services, Service A and Service B. After the EATT connection is completed, the peer must enable indications for the two services to periodically receive profile data over EATT.

Parent topic:EATT Peripheral

Supported platforms The EATT Peripheral application is supported on the following platforms:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK

Parent topic:EATT Peripheral

User interface After flashing the board, the peripheral is in idle mode (all LEDs flashing). To start advertising, press the ADVSW button. When in GAP Discoverable Mode, **CONNLED** is flashing. When a central node connects to the peripheral, **CONNLED** turns solid. The node then waits for an EATT connection request and for the client to configure indications for the two services. The service information is sent over enhanced bearers only. The values indicated are cycled between 0 and 10. To disconnect the node, hold the ADVSW button for 2-3 seconds. The node then re-enters GAP Discoverable Mode and starts advertising.

Parent topic:EATT Peripheral

Usage The application can be tested using another board flashed with the EATT Central application as described in the EATT Central Section.

Parent topic:EATT Peripheral

Parent topic:*Bluetooth LE stack and demo applications*

HCI Black Box This section describes the functionality, user interactions, and testing methods for the Bluetooth LE HCI Black Box demo application.

Description The Bluetooth LE HCI Black Box demo application gives access to the Bluetooth LE Controller via a serial interface using the HCI protocol over serial interface. Refer to the Bluetooth Specification for the format of HCI commands and events over serial interface and the full list of supported commands and events.

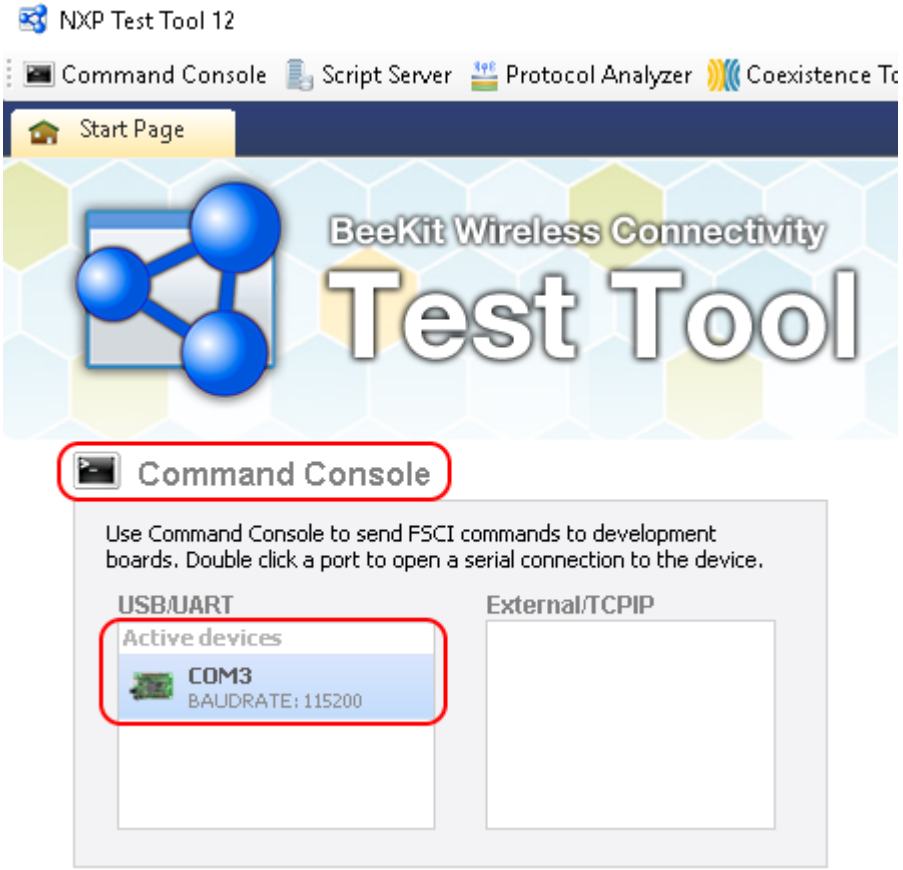
The demo can be used with the Test Tool for Connectivity Products. The Command Console application can be downloaded from the NXP website. Alternatively you can also download it using a custom application that supports the HCI protocol and commands and events over serial interface.

Note: The HCI protocol encapsulation is dependent on the type of interface it is being used on. See the Bluetooth Specification for the HCI message format on each type of supported interface.

For instructions using the Bluetooth LE HCI Black Box with a serial terminal application or the hcitool in Linux, check the article "FRDM-KW40Z Bluetooth LE Controller Usage with the Linux hcitool".

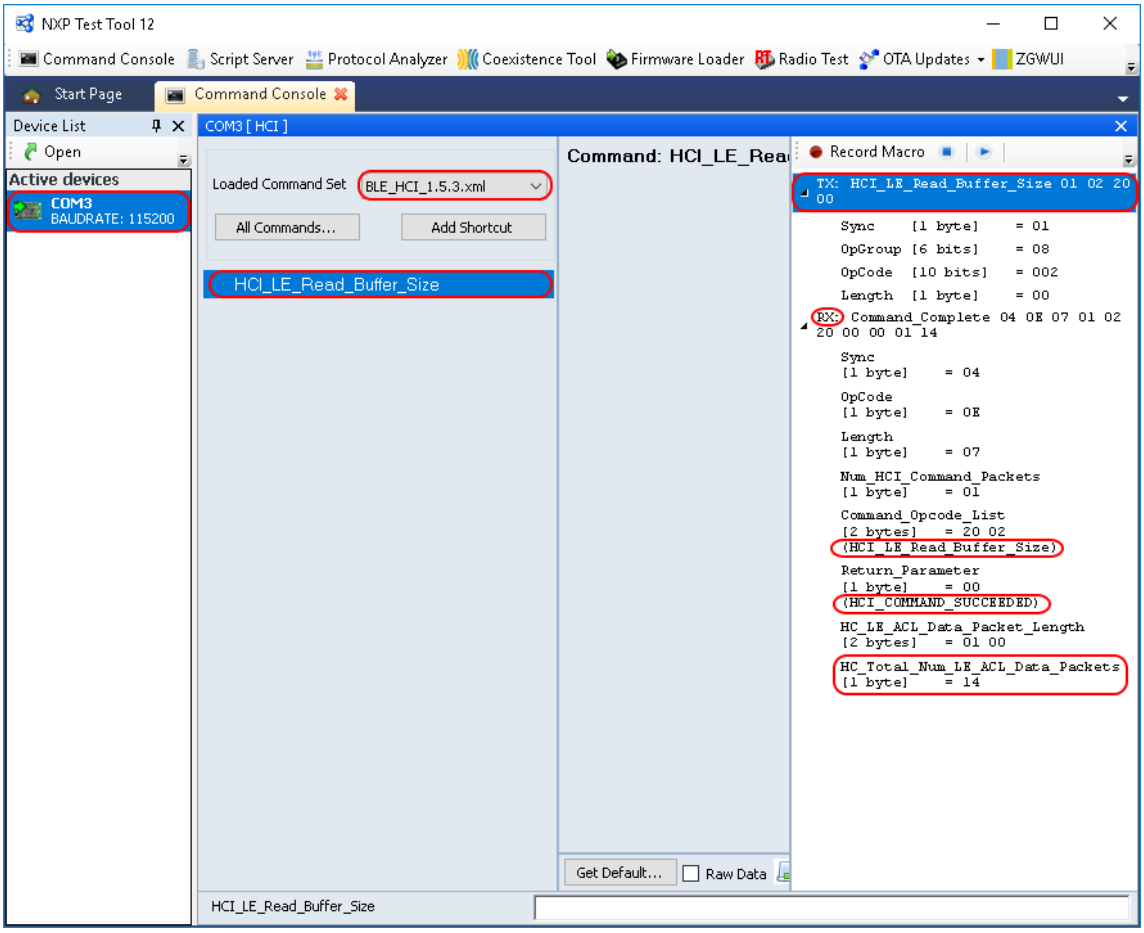
Parent topic:HCI Black Box

Supported platforms The following platforms support the HCI Black Box application:



- KW45B41Z-EVK
- FRDM-MCXW71

- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK



Parent topic:HCI Black Box

Usage with Test Tool for Connectivity products The Bluetooth LE HCI Black Box demo application is designed to be used via serial interface. This can be achieved using the TEST Tool for Connectivity Products – Command Console application as described below.

1. Download the demo application to a supported board.
2. Connect the board to a USB port of the PC. The UASB COM port drivers must be installed properly and a COM port corresponding to the board should be available.
3. Open the Test Tool application and connect to the serial port corresponding to the board on which the Bluetooth LE HCI Black Box application runs. The serial communication parameters are: baud rate 115200, 8N1, and no flow control. See the figure **Test tool command console serial port selection** below.

4. Select the appropriate Test Tool HCI XML file from the drop-down list for the release you are using. Send a few commands to the application. An example is shown in the figure **HCI black box command example** below.

Parent topic:HCI Black Box

Parent topic:*Bluetooth LE stack and demo applications*

HID Device (Mouse) This section describes implemented profiles and services, user interactions, and testing methods for the HID mouse application.

Implemented profiles and services The HID Device application implements a GATT server and the following profile and services.

- HID over GATT Profile v1.0
- Human Interface Device Service v1.0
- Battery Service v1.0
- Device Information Service v1.1

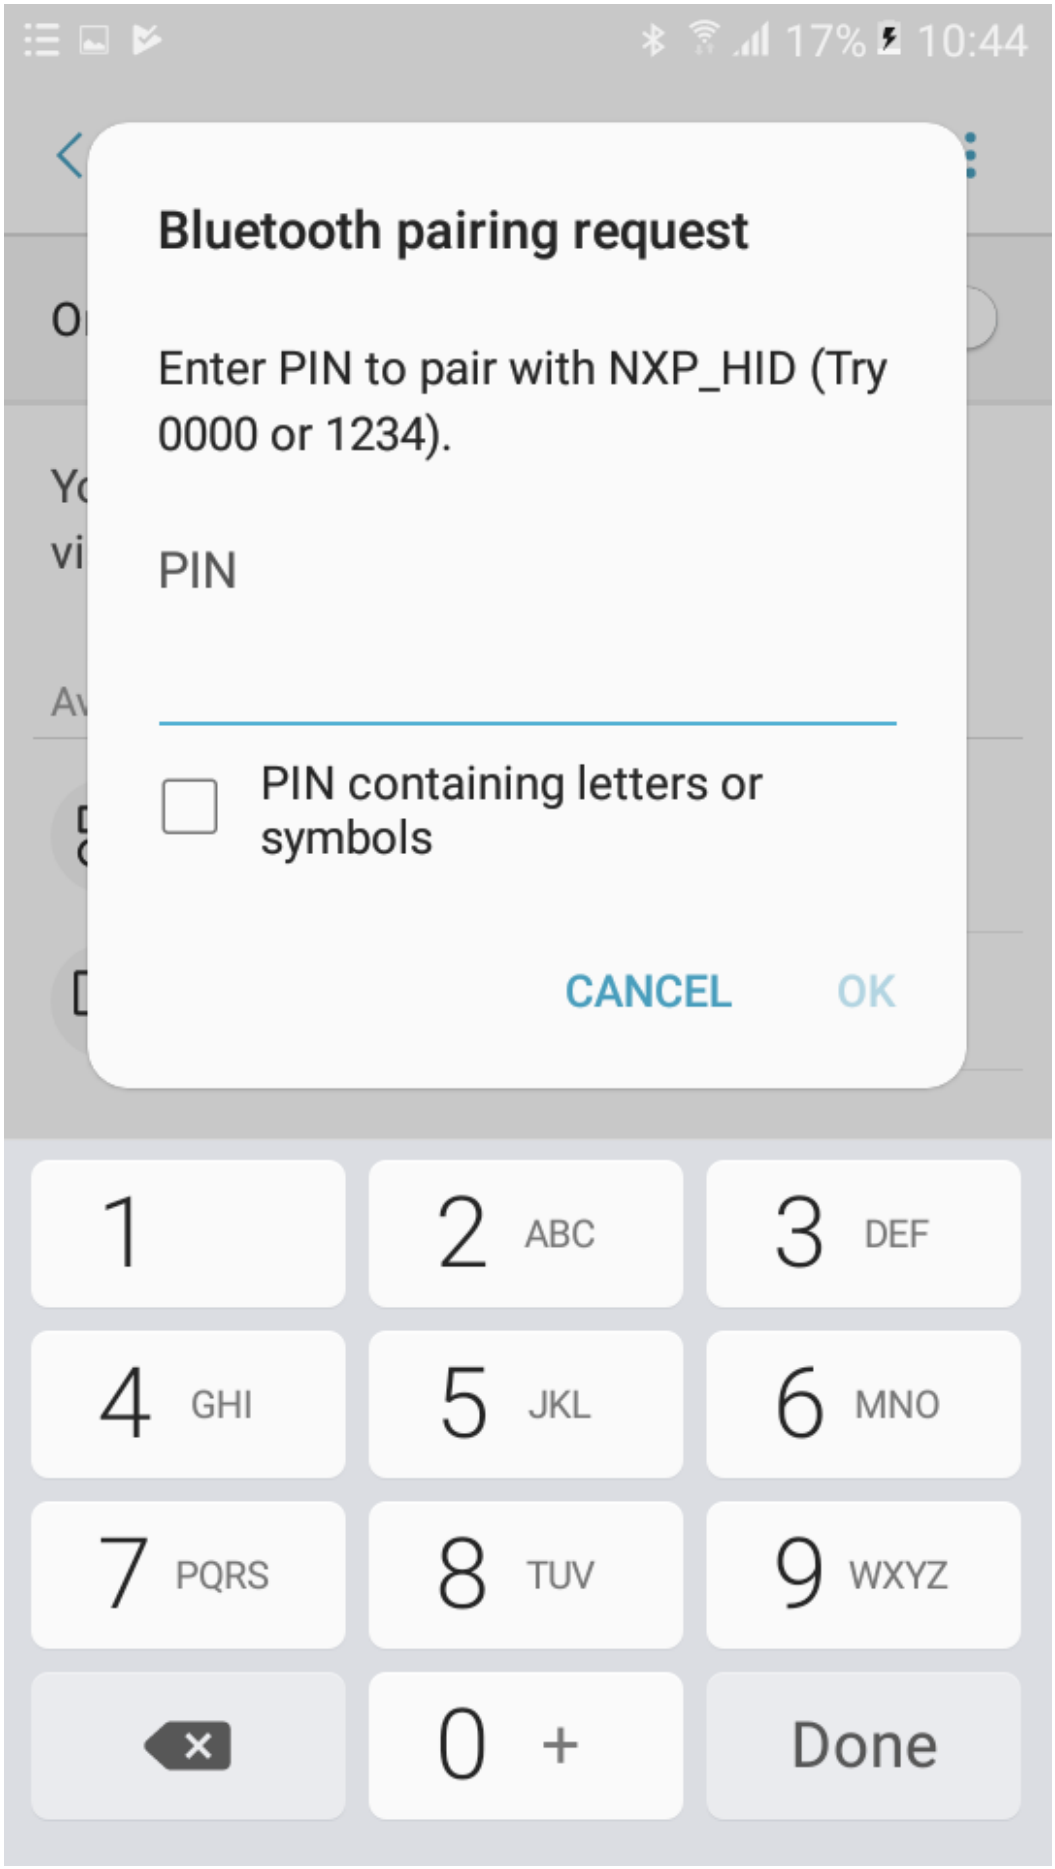
The application behaves as a GAP peripheral node. It enters GAP General Discoverable Mode and waits for a GAP central node to connect. Security on the services and bonding is enabled on this device.

When the GATT client configures notification, the application starts sending HID reports every two seconds with the movement of the MOUSE_STEP. The demo moves the cursor in a square pattern between AXIS_MIN and AXIS_MAX. The report contains 3 bytes, one for button status, one for X axis, and one for Y axis. The report descriptor matches the example in chapter E.10 from the USB Device Class Definition for Human Interface Devices (USB HID Specification), Version 1.11.

Parent topic:HID Device (Mouse)

Supported platforms The following platforms support the HID Device application:

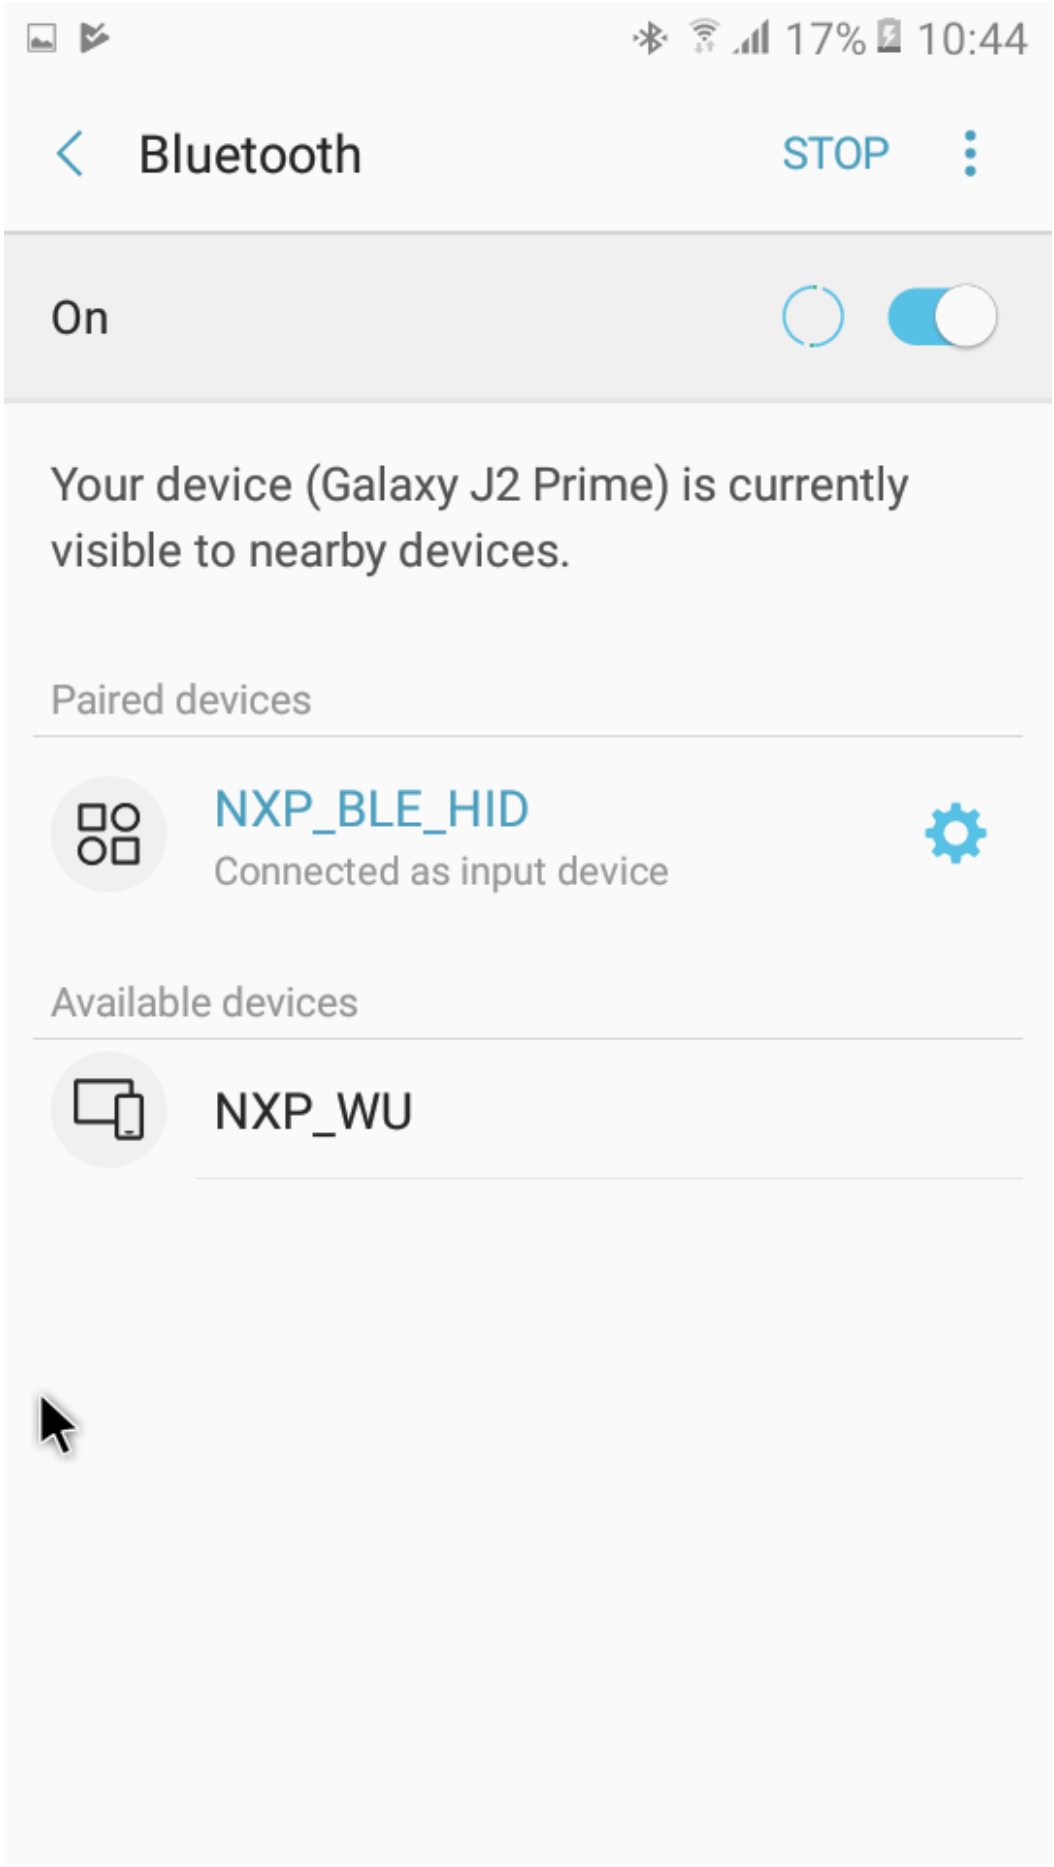
- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK



Parent topic:HID Device (Mouse)

User interface After flashing the board, the device enters Idle mode with all LEDs flashing. To start advertising, press the **ADVSW** button. In GAP Discoverable mode, **CONNLED** is flashing. When the central node connects to the peripheral, **CONNLED** turns solid. To disconnect the node, hold the **ADVSW** pressed for 2-3 seconds. The node then re-enters GAP Discoverable Mode.

Parent topic:HID Device (Mouse)



Usage The HID mouse can be connected to any Bluetooth Smart Ready products available on the market that supports HID devices or to another supported platform running the HID Host example (setup steps detailed in the HID Host section).

To make the HID mouse visible, press the **ADVSW** button to start sending advertisements, which causes CONNLED to start flashing. See the figure **Enter PIN prompt on Android platform** below.

Parent topic:*Bluetooth LE stack and demo applications*

HID Host This section presents the implemented profiles and services, user interactions, and testing methods for the HID Host application.

Implemented profiles and services The HID Host application implements a GATT client or server for the following profile and service.

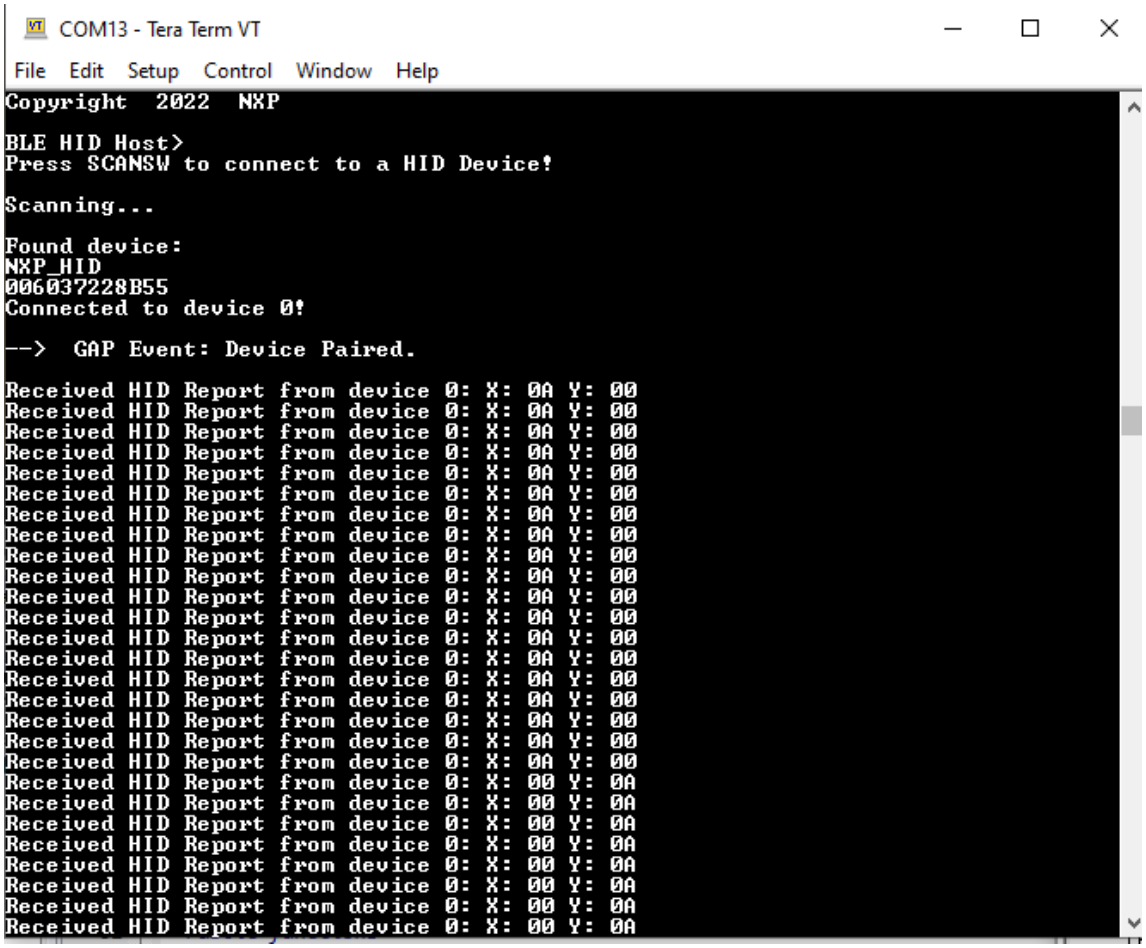
- HID over GATT Profile v1.0
- Battery Service v1.0
- Device Information Service v1.1

The application behaves as a GAP central node. It enters the GAP Limited Discovery Procedure and searches for HID devices to connect to. After connecting with the peripheral, it configures notifications and displays the received HID reports on a terminal connected to the UART port. The application uses pairing with bonding by default. When connected with the HID Device application, it sends the 999999 passcode to the host stack by default.

Parent topic:HID Host

Supported platforms The following platforms support the HID Host application:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK

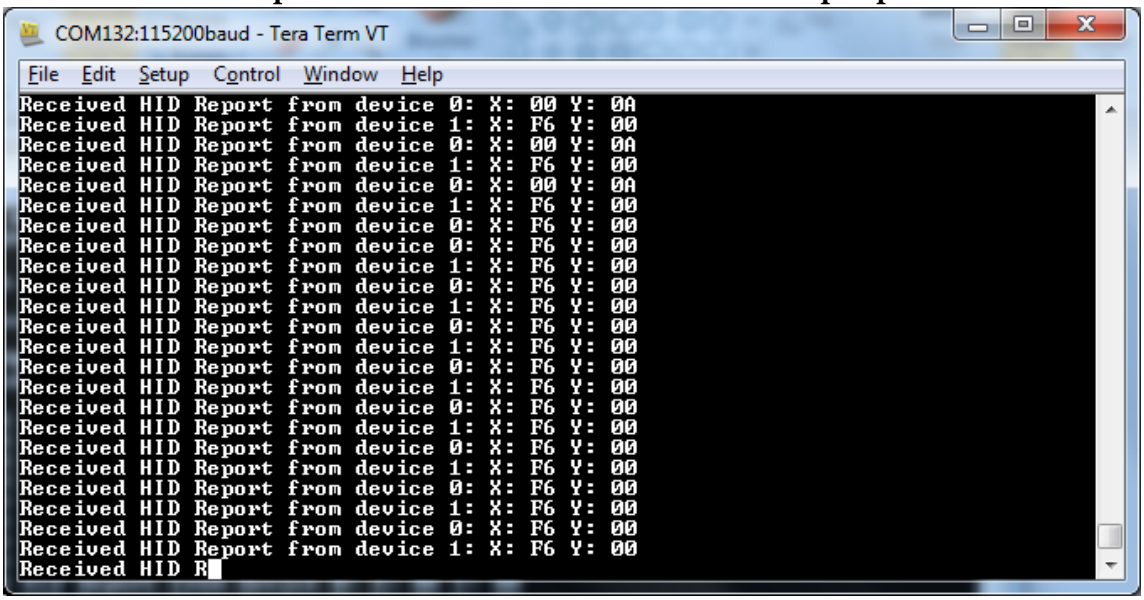


Parent topic:HID Host

User interface After flashing the board, the device is in idle mode (all LEDs flashing). To start scanning, press the **SCANSW** button. When in GAP Limited Discovery Procedure, **CONNLED** is flashing. When the central node connects to the peripheral, **CONNLED** turns solid. To disconnect the node, hold the **SCANSW** button pressed for 2-3 seconds. The node then re-enters GAP Limited Discovery Procedure.

Parent topic:HID Host

Usage The application is built to work only with the HID Device application presented in HID Device (Mouse). It supports up to 2 peripherals connected at the same time.



1. Open a serial port terminal and connect it to board, in the same manner described in Testing devices. The start screen is displayed after the board is reset.
2. To start scanning for devices, press the **SCANSW** button on the HID Host board. To make it enter discoverable mode, perform the same step on the HID device board. The host connects with the board after it sees it advertise the HID service, connects to it, and configures report notifications. The device then starts sending HID reports, as shown in Figure.

HID host

3. To connect a second HID device, press again the **SCANSW** button on the HID Host board to start scanning for devices. Do the same on the second HID device board to make it enter discoverable mode. The host connects with the board after it sees it advertise the HID service, connects to it, and configures report notifications. The device then starts sending HID reports. The console displays reports from both devices, as shown in Figure.

Tera Term – Output Console on HID Host with 2 peripherals connected

Parent topic:*Bluetooth LE stack and demo applications*

Low-power temperature sensor and collector This section describes the implemented profiles and services, user interactions, and testing methods for the temperature sensor application.

Implemented profiles and services The Temperature Sensor application implements a GATT server, a custom profile and the following services.

- Temperature Service (UUID: 01ff0200-ba5e-f4ee-5ca1-eb1e5e4b1ce0)
- Battery Service v1.0
- Device Information Service v1.1

The application behaves as a GAP peripheral node. It enters GAP General Discoverable Mode and waits for a GAP central node to connect and configure notifications for the temperature value.

The Temperature service is a custom service that implements the Temperature characteristic (UUID: 0x2A6E) with a Characteristic Presentation Format descriptor (UUID: 0x2904), both defined by the Bluetooth SIG.

The Temperature Collector application implements a GATT client or server for the following profile and services.

- Temperature Service (UUID: 01ff0200-ba5e-f4ee-5ca1-eb1e5e4b1ce0)
- Battery Service v1.0
- Device Information Service v1.1

The application behaves as a GAP central node. It enters GAP Limited Discovery Procedure and searches for sensor devices to pair with. After pairing with the peripheral, it configures notifications and displays temperature values on a terminal connected to the UART port.

Both application uses pairing with bonding by default. When connected with the Low-Power Temperature Sensor application, the collector sends the 999999 passcode to the host stack by default.

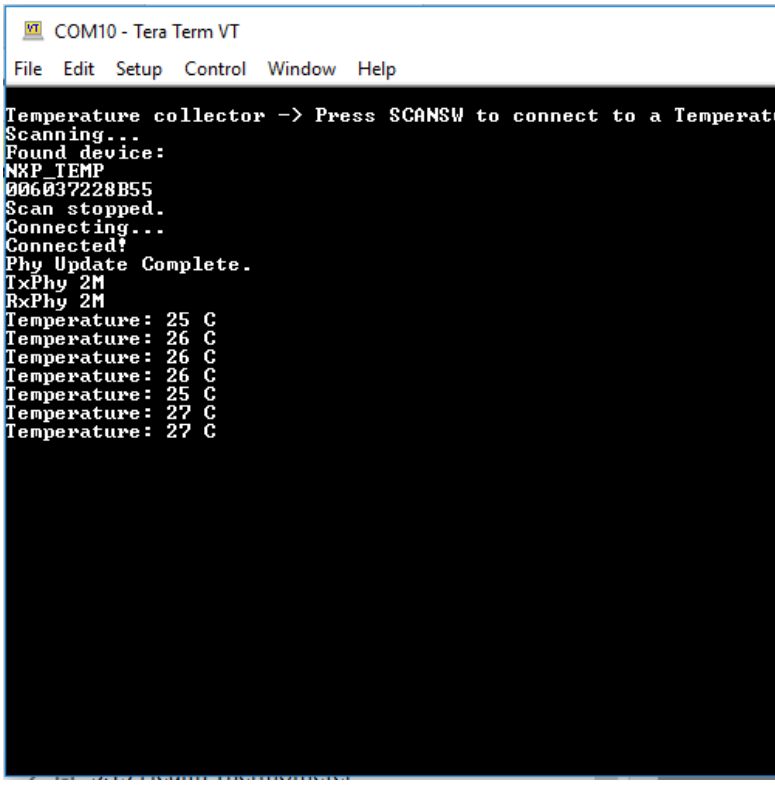
Parent topic: Low-power temperature sensor and collector

Supported platforms The Temperature Sensor and Collector applications are supported by the following platforms:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK

Parent topic: Low-power temperature sensor and collector

User interface After flashing the board, both nodes enter Low-power mode. In case the sensor is put in deep sleep, press **WAKESW** or **RESET**. To flash the board in case the sensor is put in deep sleep, press either **WAKESW** or **RESET** button. By default, the application is configured to be in low power mode, which disables LED support.



The user can manually change this configuration and enable LED support, else all subsequent LED behavior references are ignored and all LEDs are off. The devices disconnect and enter Deep-sleep only if low power is enabled. When the node is awake and communicating, **CONNLED** is on. To wake up the node, press the **WAKESW** button.

Parent topic: Low-power temperature sensor and collector

Usage The setup requires two supported platforms, one for the temperature sensor and one for the temperature collector.

1. Open a serial port terminal and connect it to the temperature collector board, in the same manner as described in Testing devices. The start screen is displayed after the board is reset. At first the LEDs are off on both devices.
2. To start advertising on the sensor, press the WAKESW button and CONNLED lights up. The sensor enters into the Deep-sleep mode, which means that the MCU wakes up on any packet from the Link layer, in this case the connect request. If no connection is established in an interval of 30 seconds, the sensor stops advertising and enters into the Deep-sleep mode again. CONNLED turns off.
3. To start scanning on the collector, press the WAKESW button and CONNLED lights up. The device wakes up, enters into the Deep-sleep mode, scans, and connects to a compatible sensor device. If no connection is established within 30 seconds, the collector stops scanning and enters Deep-sleep mode again. CONNLED turns off.
4. If the collector connects to a sensor node, it bonds (if no bond was previously made), does service discovery (only the first time it connects with the sensor), and configures notification and waits for notifications from the sensor for 5 seconds. If no data is sent, the node disconnects and re-enters Deep-sleep mode. The sensor exits low power and sends a notification with the value of the temperature read through an ADC from the thermistor, if present, or random generated if not.

   Once the connection is established, the PHY is automatically updated to 2M, if both the sensor and the collector support this feature as shown in the figure below. The PHY update is configurable from the application.

Output Console on Temperature Collector

5. Subsequent key pressing triggers other notifications for the collector. If no key is pressed in an interval of 5 seconds, the sensor node disconnects and re-enters Deep-sleep mode.

Parent topic: Low-power temperature sensor and collector

Parent topic:*Bluetooth LE stack and demo applications*

Low-power extended advertising Peripheral and Central This section describes the implemented profiles and services, user interactions, and testing methods for the adv_ext_peripheral and adv_ext_central applications.

Implemented profile and services The adv_ext_peripheral application implements a GATT server, a custom profile and the following services.

- Temperature Service (UUID: 01ff0200-ba5e-f4ee-5ca1-eb1e5e4b1ce0)
- Battery Service v1.0
- Device Information Service v1.1

The application behaves as a GAP peripheral node. It enters GAP General Discoverable Mode and waits for a GAP central node to connect and configure notifications for the temperature value.

The Temperature service is a custom service that implements the Temperature characteristic (UUID: 0x2A6E) with a Characteristic Presentation Format descriptor (UUID: 0x2904), both defined by the Bluetooth SIG.

The adv_ext_central application implements a GATT client or server for the following profile and services.

- Temperature Service (UUID: 01ff0200-ba5e-f4ee-5ca1-eb1e5e4b1ce0)
- Battery Service v1.0
- Device Information Service v1.1

The application behaves as a GAP central node. It enters GAP Limited Discovery Procedure and searches for peripherals devices to pair with. After pairing with the peripheral, it configures notifications and displays temperature values on a terminal connected to the UART port.

Both applications use pairing with bonding by default. When connected with the Low-Power Extended Advertising Peripheral application, the Extended Advertising Central application sends the 999999 passcode to the host stack by default.

To enable PAWR, set the gAppPAWRSupport_d define TRUE in app_preinclude.h.

In case PAWR is enabled and more than one ext_adv_centrals are to be synced with the PAWR train, a different response slot may be configured for each board using the gUserDefinedResponseSlot_c define in app_preinclude.h to avoid collisions. Otherwise, a random response slot will be chosen by the application after reset.

Note: For KW45/K32W1 platforms, the PAWR usage requires the experimental NBU image from middleware\wireless\ble_controller\bin to be downloaded. Also the lib_ble_host_central_cm33_x.a from the middleware\wireless\bluetooth\host\lib should be replaced with the lib_ble_OPT_host_cm33_x.a from the middleware\wireless\bluetooth\host\lib_exp.

Parent topic: Low-power extended advertising Peripheral and Central

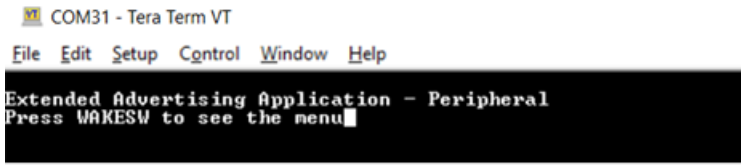
Supported platforms The following platforms support Extended Advertising Peripheral and Central applications:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK

Deep-sleep mode is used by default.

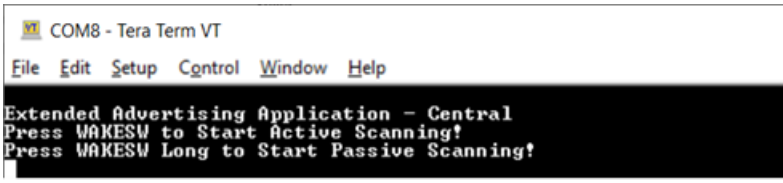
Parent topic: Low-power extended advertising Peripheral and Central

User interface After flashing the board, both nodes enter Deep-sleep mode. To flash the board again, press **WAKESW**. The application default configuration enables low power that disables LED support. The user disables low power and enables LED support setting the gAppLowpowerEnabled_d define to 0. To wake up the node, press the **WAKESW** button. Both applications provide guidance over the UART.



Open a serial port terminal using the following settings:

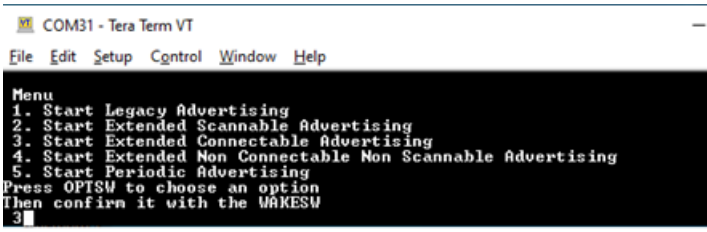
baud rate 115200, data bits 8, parity none, stop bits 1.



Parent topic: Low-power extended advertising Peripheral and Central

Usage The setup requires two supported platforms, one for the adv_ext_peripheral, and one for the adv_ext_central.

1. Open a serial port terminal and connect it to each platform with the settings provided in the previous paragraph. The start screen is displayed after the boards are reset as shown in the figures below.



Advertizing external Peripheral start screen

Advertizing external Central start screen

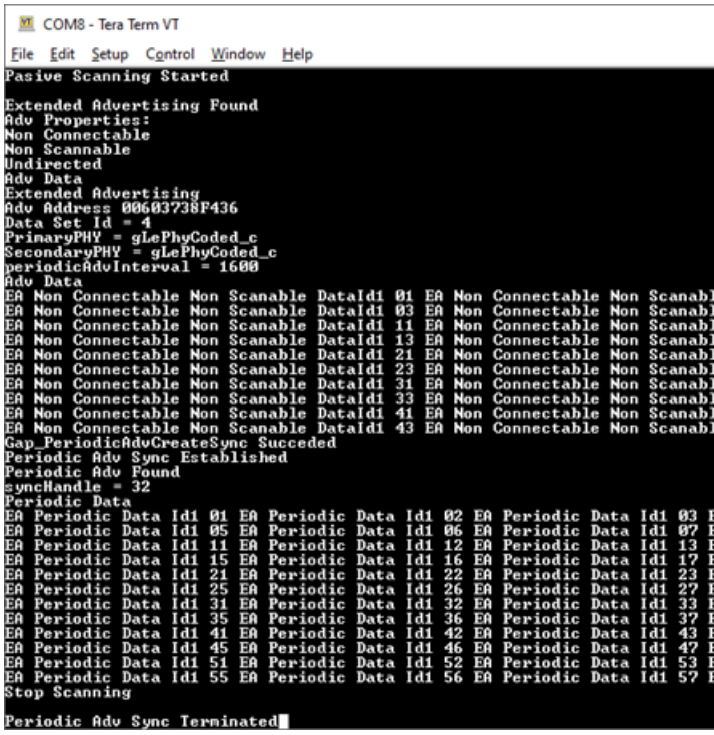
2. On the board that implements the adv_ext_peripheral application, press the **WAKESW** button. The board exits Deep-sleep mode and displays the menu as shown in the figure below.

Choosing a menu option on adv_ext_peripheral

Use the **OPTSW** to choose an option. The option printed on the bottom changes every time the switch is pressed. When the option matches your intention (For example, 3 Starts Extended Connectable Advertising), press the **WAKESW** again to make a decision. The advertising type chosen is started and the board starts entering low-power between advertising events.

Next time, the **WAKESW** is pressed, an updated menu is printed (For example, at option 3 Stop Extended Connectable Advertising). There is no timeout for advertising. The board continues advertising until it is stopped, or a connection is established (for legacy and extended connectable advertising only) with an adv_ext_central device.

The connection is terminated five seconds after the central device configures notifications for the temperature value. When all advertising is off and all connections are terminated, the board enters low-power mode until the **WAKESW** button is pressed again.



When gAppLowpowerEnabled_d is set 0, LEDs are enabled. The ADVLED flashes whenever an advertising starts and is ON otherwise. The CONNLED flashes whenever there is a connection under way and is ON otherwise.

When PAWR is started , advertising data is transmitted on subevents zero and three and responses are expected on all 5 configured response slots of these subevents. The central application responds to the periodic data received with a six bytes data composed of a three bytes random number followed by a three bytes hash performed over the random number using the local IRK in the same fashion the RPA are generated. The advertiser prints the responses, uses the bonded devices IRKs to generate the hash over the random number and attempts to connect over PAWR with the responder in case the hashes match.

```
PAWR Started
PAWR Set Subevent Data Complete
Periodic advertising response received
Adv Handle: 0
Subevent: 0
Response slot: 2
Response data: EFBE6E573231
Periodic advertising response received
Adv Handle: 0
Subevent: 3
Response slot: 2
Response data: 021CED6395B8
PAWR Set Subevent Data Complete
```

3. On the board that implements the **adv_ext_central** application, there are two options: Press **WAKESW** to start active scanning or long press **WAKESW** to start passive scanning. If catching extended scannable advertising is not an option, choose passive scanning. Otherwise, select active scanning. The device wakes up, starts scanning, and enters Deep-sleep mode. The scanning ends when the 60 seconds timeout is reached or when a connection with an adv_ext_peripheral device is established.

   During scanning, all advertisements caught from adv_ext_peripheral devices are displayed on the terminal window as shown in Figure. When an extended non-connectable, non-scannable advertising with a periodic advertising attached is detected, the *adv_ext_central*device attempts to sync with the periodic advertising train and prints the periodic advertising data on the terminal window.

Advertising caught on adv_ext_central console

If the PAWR support is enabled and the periodic advertising train the adv_ext_central has synced to is with responses the application attempts to sync with the subevents zero and three, periodic advertising data printed being slightly different. Also, the application responds to the periodic data received with a six bytes data composed of a three bytes random number followed by a three bytes hash performed over the random number using the local IRK in the same fashion the RPA are generated. The advertiser uses the bonded devices IRKs to generate the hash over the random number and attempts to connect over PAWR with the responder in case the hashes match.

```
Passive Scanning Started

4. If the **adv_ext_central** connects to an **adv_ext_peripheral** device, it bonds (if no bond was previously made), does service discovery (only the first time it connects with the peripheral), configures notification and waits for notifications from the peripheral. If no data is sent within 5 seconds, the node disconnects and reenters Deep-sleep mode. The peripheral sends a notification with the value of the temperature read through an ADC from a thermistor, if present, or randomly generated, if not. When the central receives the notification, it displays it on the terminal window and disconnects in 5 seconds as shown in the figure below.

   When the 60 seconds timer expires or the connection ends, the device reenters Deep-sleep mode until the WAKESW is pressed again and all syncs with periodic advertising trains are terminated. If gAppLowpowerEnabled_d is set 0, LEDs are enabled. The SCANLED flashes, whenever the device is scanning and is ON otherwise. The CONNLED flashes, whenever there is a connection under way and is ON otherwise. See the figure below.

Connection on adv_ext_central console

   When the PAWR support is enabled and a connection with a previously bonded device takes place over PAWR, the applications behavior is similar except in this case the adv_ext_central's role is peripheral and adv_ext_peripheral's role is central.

```

Parent topic: Low-power extended advertising Peripheral and Central

Parent topic:*Bluetooth LE stack and demo applications*

Over the Air Programming (OTAP) This section describes the implemented profiles and services, user interactions, and testing methods for the Bluetooth LE OTAP application.

Implemented profile and services The Bluetooth LE OTAP applications implement the GATT client and server for the custom Bluetooth LE OTAP profile and service.

- **Bluetooth LE OTAP Service** (UUID: 01ff5550-ba5e-f4ee-5ca1-eb1e5e4b1ce0)

The Bluetooth LE OTAP Service is a custom service which has 2 characteristics.

- **OTAP Control Point Characteristic** (UUID: 01ff5551-ba5e-f4ee-5ca1-eb1e5e4b1ce0). This characteristic can be written and indicated to exchange OTAP Commands between the OTAP Server and the OTAP Client. Data chunks are not transferred using this characteristic.
- **OTAP Data Characteristic**(UUID: 01ff5552-ba5e-f4ee-5ca1-eb1e5e4b1ce0). This characteristic can be written without response by the OTAP Server to transfer image file data chunks to the OTAP Client only when an image block transfer is requested via the ATT transfer method. Data chunks can also be transferred via the L2CAP credit-based PSM channels method.

The demo runs using 3 applications: an OTAP Client embedded application, an OTAP Server embedded application, and an Over the Air Programming PC application. The OTAP Client embedded application has two versions, an ATT version and a L2CAP version each using a different transfer method.

The embedded OTAP Server application is a GAP Central application which scans for devices advertising the Bluetooth LE OTAP service. After it finds one, it connects to it and configures the OTAP Control Point CCC Descriptor to receive ATT Indications from the device then it waits for OTAP commands from this device.

Once commands start arriving from the OTAP Client via ATT Indications the OTAP Server relays them via serial interface to a PC application which responds. The responses are then sent back to the OTAP Client by writing the OTAP Control Point Characteristic. The embedded OTAP Server application effectively acts as a relay between the OTAP Client to which the image is sent over the air and the Over the Air Programming PC application which has an OTAP image file constructed using a binary '*.srec*' image or a '*.bin*' image.

The OTAP Client is a GAP Peripheral which advertises the Bluetooth LE OTAP Service and waits for a connection from an OTAP Server. After an OTAP Server connects, the OTAP Client waits for it to write the OTAP Control Point CCCD and then starts sending commands via ATT Indications. If the OTAP Client is configured to ask the data transfer via the L2CAP CoC PSM, it registers and tries to connect a predetermined L2CAP PSM before sending any commands to the OTAP Server.

Parent topic: Over the Air Programming (OTAP)

Supported platforms The following platforms support the OTAP applications:

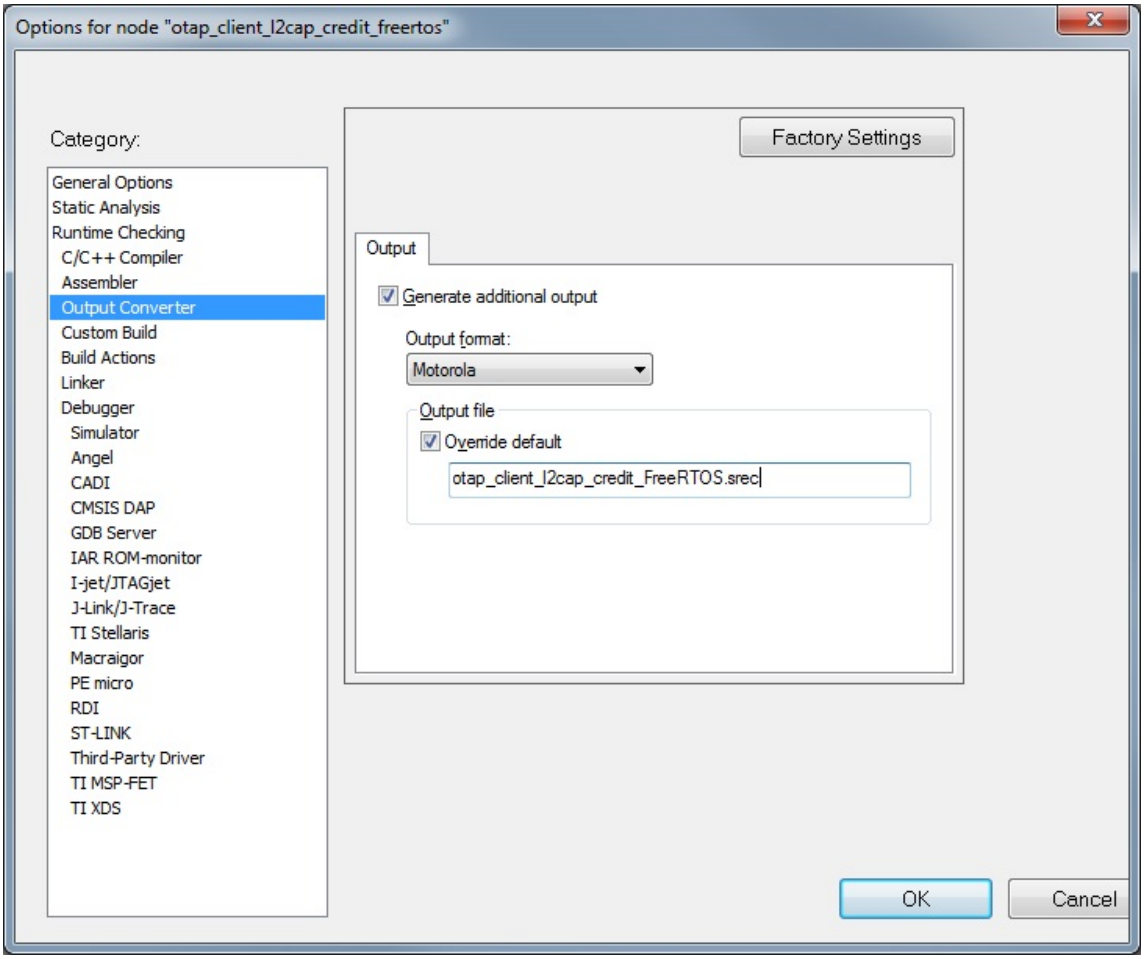
- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK
- FRDM-MCXW23
- MCXW23-EVK

Parent topic: Over the Air Programming (OTAP)

User interface After flashing two boards with the OTAP Server and OTAP Client applications respectively, the devices are in Idle mode (all LEDs flashing). To start advertising, press the **ADVSW** button on the OTAP Client. To start scanning, press the **SCANSW** button on the OTAP Server. After the two devices connect and start exchanging commands. **CONNLED** becomes solid on the OTAP Server and on the OTAP Client.

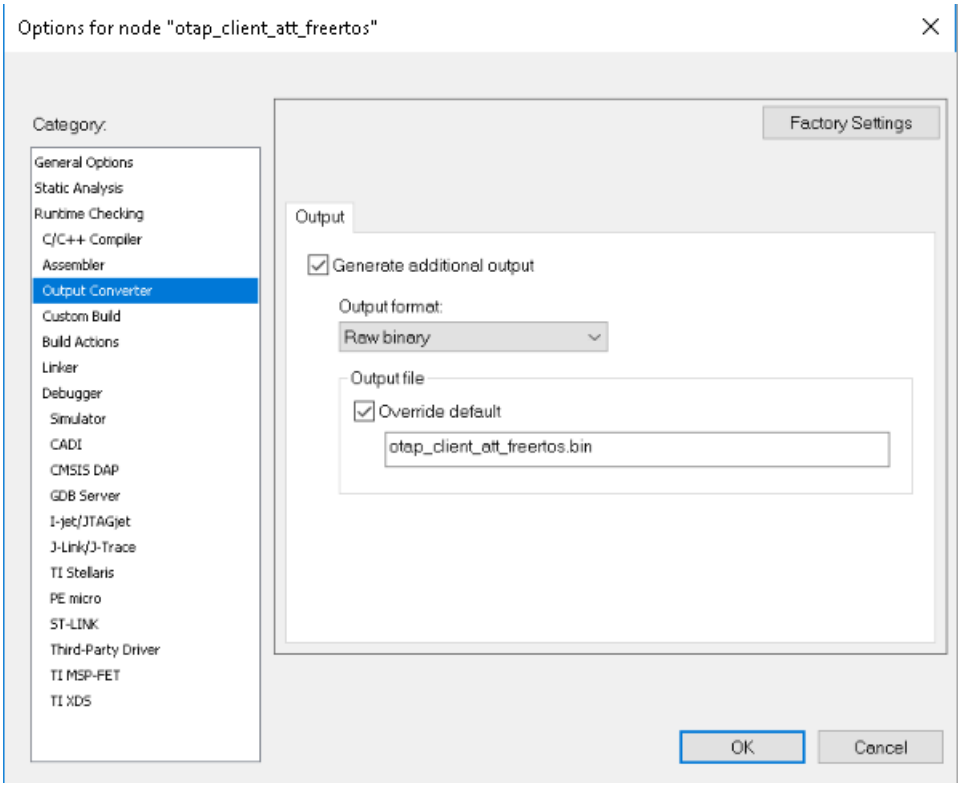
Start the OTAP Server PC application after the embedded applications are flashed to the boards. The application creates an OTAP image file using the provided executable .srec or .bin file. It then connects to the embedded OTAP Server via the configured serial interface and waits for commands. The application shows details about the image file creation and allows the OTAP upgrade image file header to be configured. The log view of the application displays the interactions between the OTAP Client and the OTAP Server.

Parent topic: Over the Air Programming (OTAP)



Usage with Over The Air Programming Tool Below is a list of requirements for usage with Test Tool for Connectivity products:

- Over The Air Programming Tool 1.4.0 or newer on CONNECTIVITY-TOOL-SUITE
- Serial COM port drivers – these are board-specific.



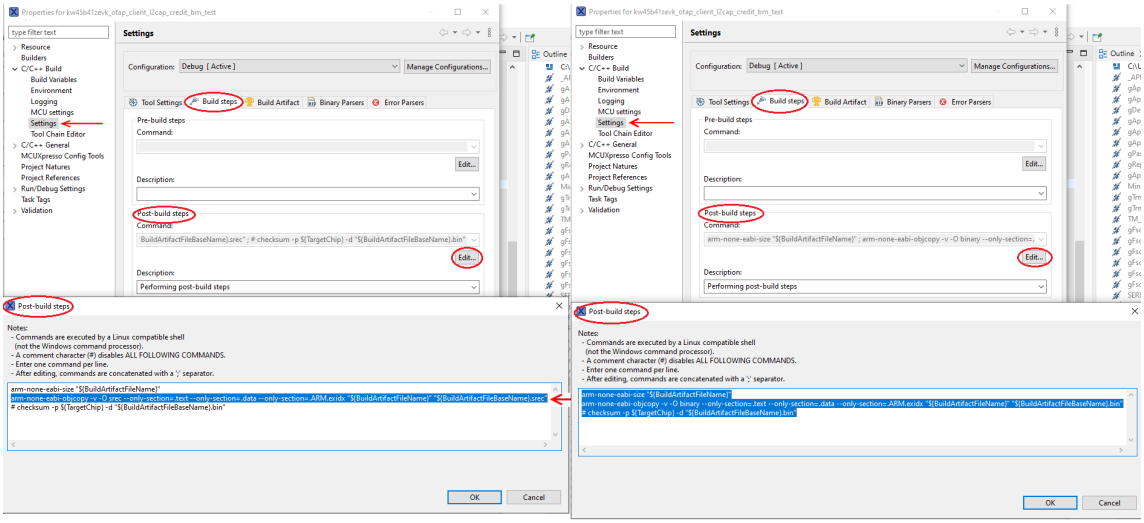
To run the application, follow the steps below:

1. Flash the OTAP Server onto a supported platform and the OTAP Client to another supported platform. Make sure the board running the OTAP Server is connected to your PC and your PC has appropriate drivers for the USB to serial device on that board.
2. Create the application to send over the air. The executable must be provided in the .srec or .bin format. The .srec format executable can be obtained by using the IAR Output Converter and setting the output format to Motorola as shown in in the figure below.

   When compiling an image for the Over-the-Air update, the gEraseNVMLink_d linker symbol must be set to 0.

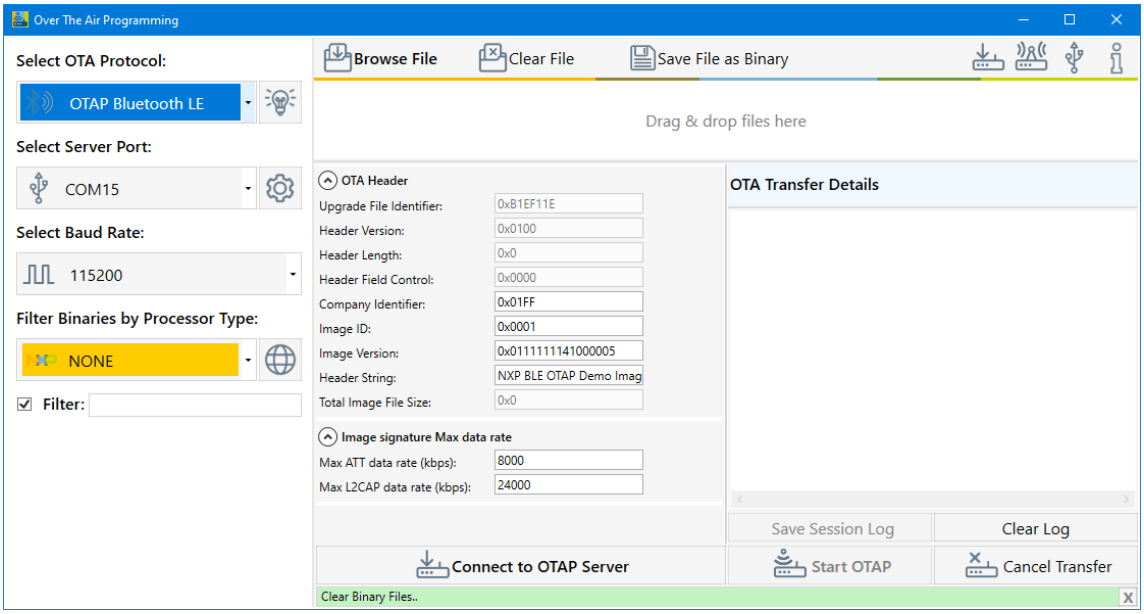
3. To obtain a .bin file from IAR, select the **Raw binary** option in the **IAR Output Converter** as seen in the in the figure below.

4. To obtain a .bin file from MCUXpresso IDE, go to the **Project properties -> Settings -> Build steps**window and press the **Edit**button for the Post-build steps. A **Post-build steps** window shows up. In this window, add the following command:



```
arm-none-eabi-objcopy -v -O binary  --only-section=.text
 --only-section=.data
--only-section=.ARM.exidx "${BuildArtifactFileName}"
"${BuildArtifactFileBaseName}.bin"
```

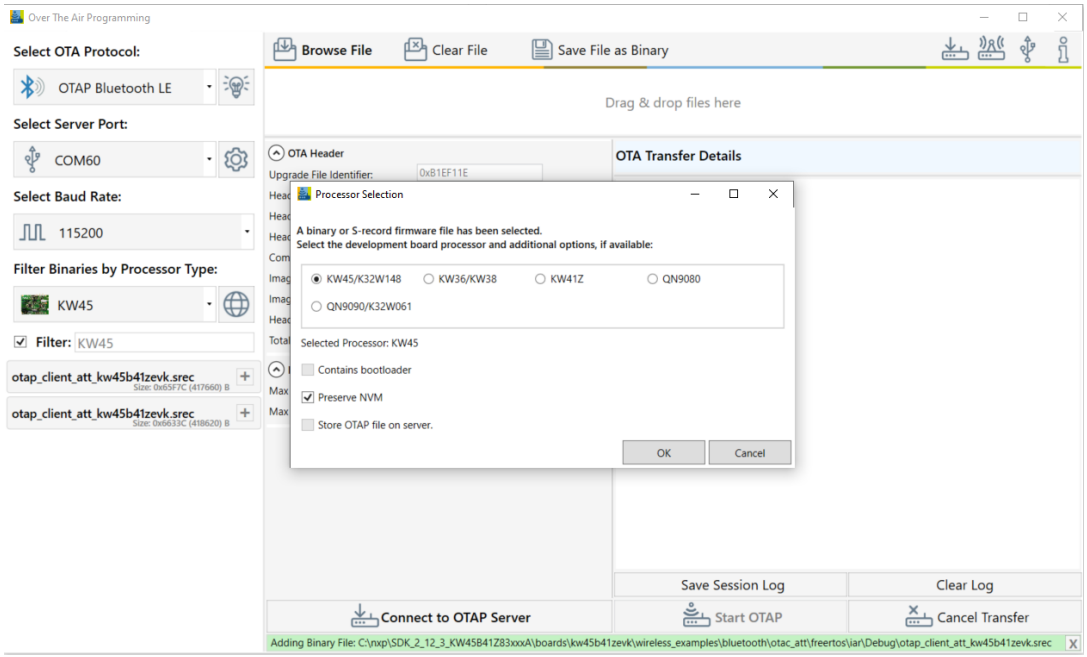
In case the command already exists, uncomment it by removing the '#' character at the beginning.



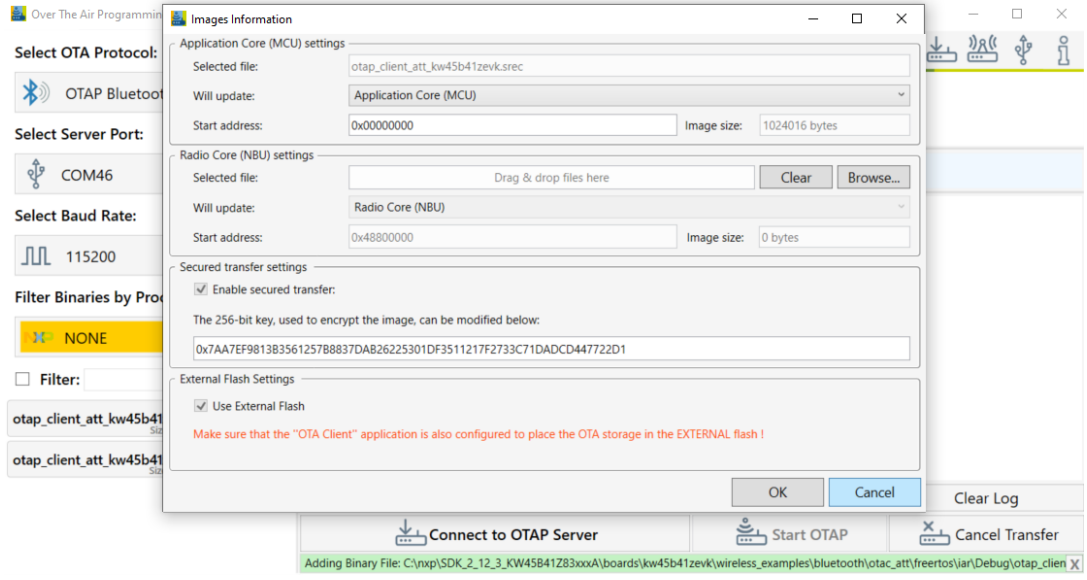
To obtain a .srec (.s19) file, add or uncomment the following post-build command in the same window:

```
arm-none-eabi-objcopy -v -O srec  --only-section=.text
 --only-section=.data --only-section=.ARM.exidx"
${BuildArtifactFileName}" "${BuildArtifactFileBaseName}.s19"
```

This window is shown in the figure below.



5. Start the **Over The Air Programming** application and select "**OTAP Bluetooth LE**" from the "**Select OTA Protocol**" combo box as shown in the figure below.

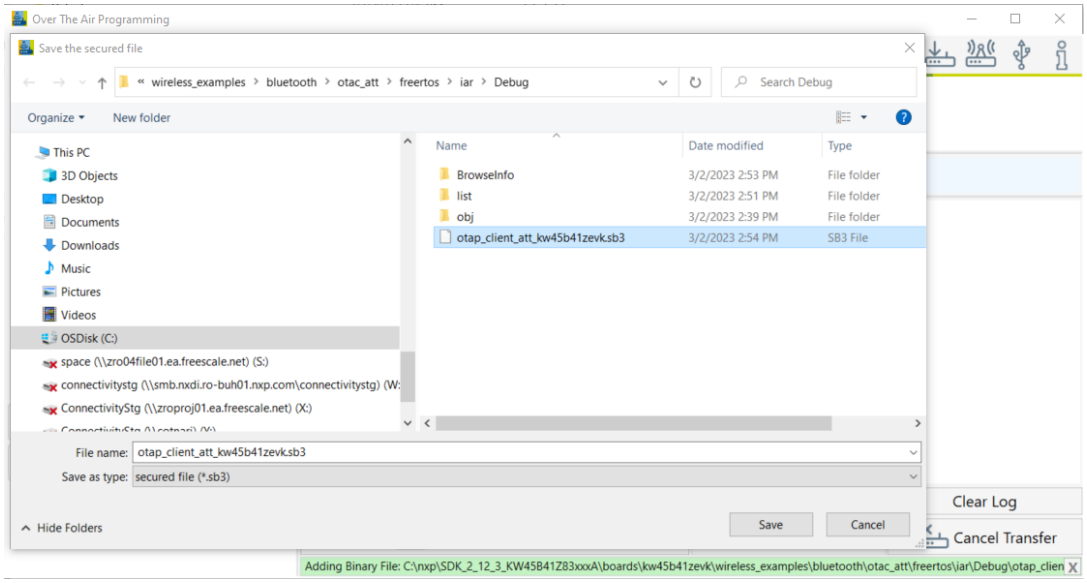


6. **Load the image file into the application, then configure the image file header and start the OTAP Server:**

   - To select the updated image In the Over the Air Programming tool, select the "**Browse File**" button and then navigate to the .srec or .bin file containing the image to be sent to the OTAP Client. After the .srec or .bin file is chosen, a pop-up window asks to choose the target processor. In this example, the **KW45/K32W** processor will be used. Choose the **KW45/K32W** processor and press **OK**. See the figure below.

   - Once the processor is selected, a new pop-up window would appear that allows selecting the type of image as shown in the figure below. (In the specified case, we selected the KW45Z/KW45Z/K32W1(MCU).

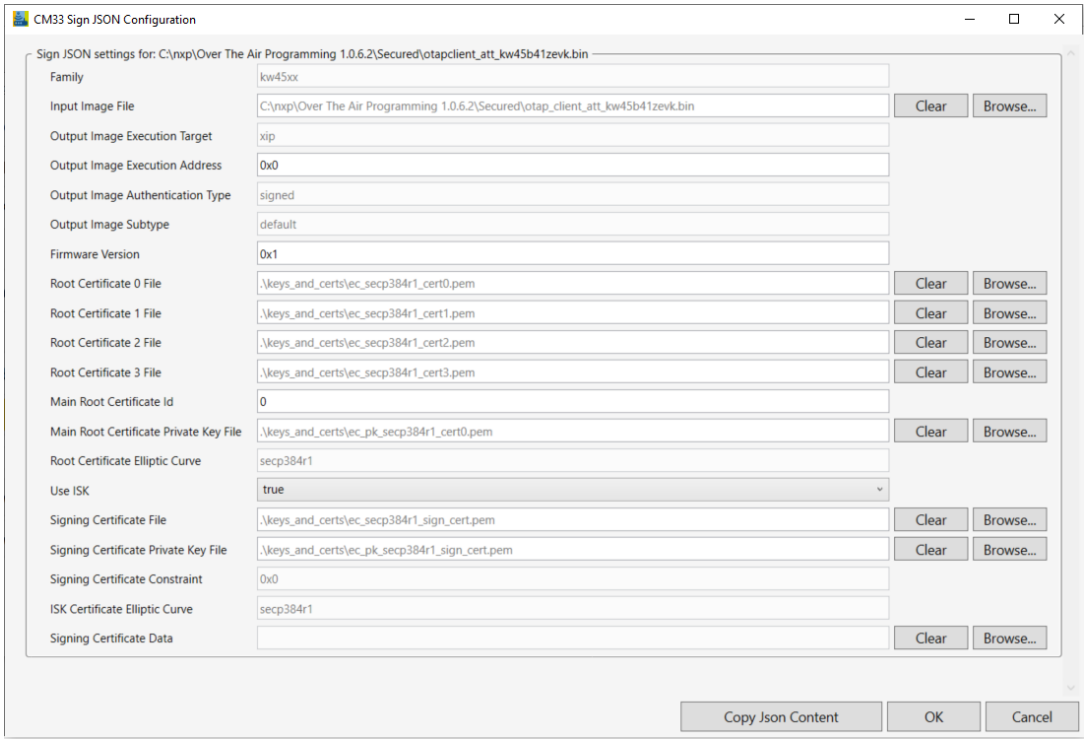
   - To update the KW45B/KW32W1 (radio) image, select it by pressing the "**Browse**" button in the M3 group. Then navigate to the .bin file as shown in the figure below.



- If the OTA client has configured external memory support, then "**Use External Flash**" checkbox must be checked as in the figure below. If the OTA client has configured internal memory support, the checkbox must be left unchecked.

  This checkbox (if checked) instructs the OTA client bootloader to erase all the internal storage. This must be done only if external memory support is used as shown in the figure below. .

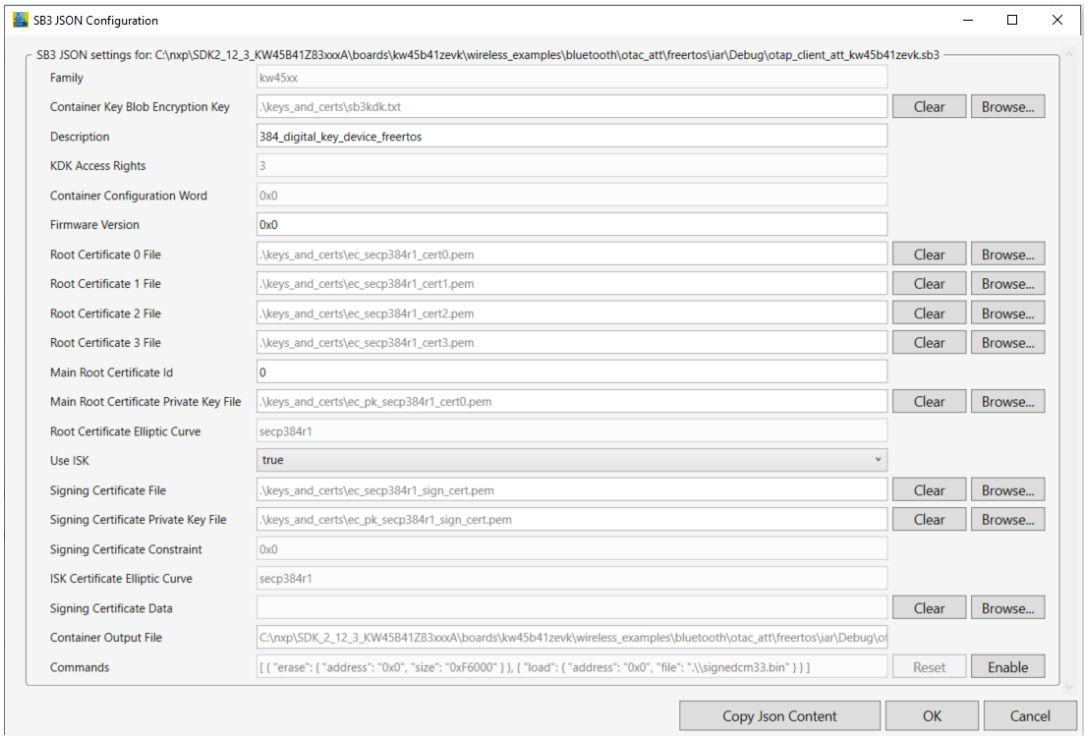
At this moment, click the **OK**button. A new window appears that prompts you to enter a location where the secured file should be stored. By default, the location of the original file is selected. See the figure below.



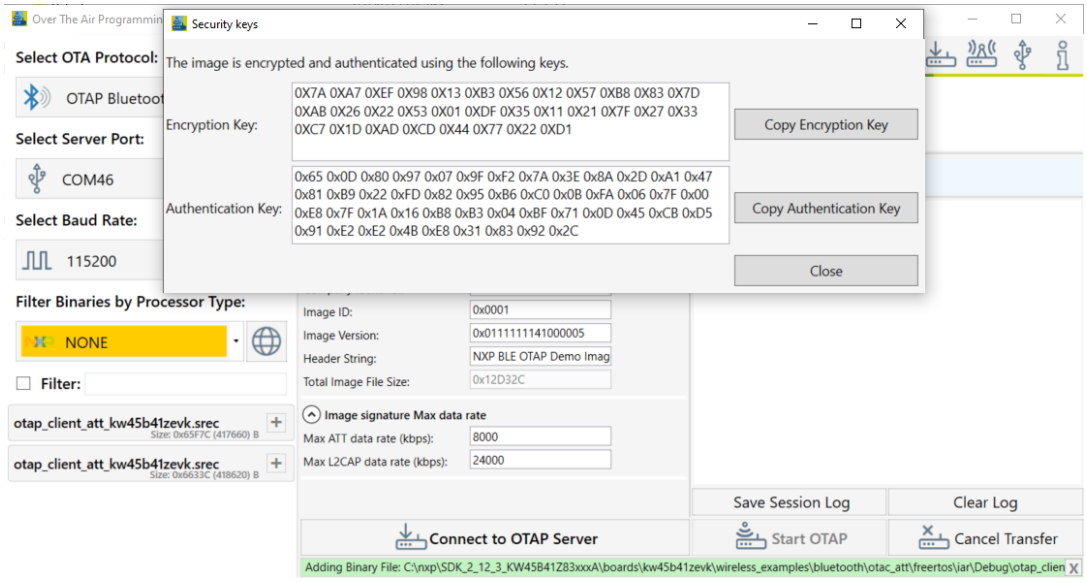
Note: The extension of the secured file is *.sb3. See the figure below.

- You can now configure two different JSON files, used to:
  - Sign the file that is uploaded to the MCU if an MCU file was selected.
  - Create the **.sb3*container that is sent OTA. The **.sb3* file can contain only the MCU file, only the radio file, or both.

If you select a file that is written on the MCU, a new window appears as shown in the figure below. This window helps in configuring the root certificates and signing the certificates, by either dragging and dropping, or browsing for new files. For details on each field of the JSON, see */Documentation/KW45JsonDescription.pdf* provided with Over the Air Programming tool.



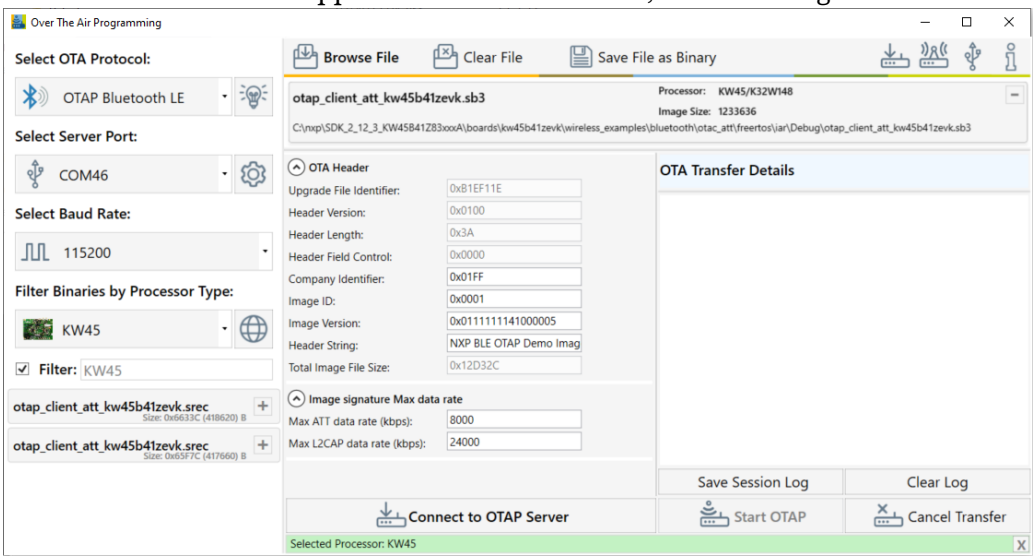
By default, the JSON is configured for the demo applications to run as shown in the figure below.



After configuring the JSON file used for signing the MCU file, a new similar window appears. As shown in the Figure, the window is designed for configuring the **.sb3* con-

tainer. This window helps you to configure the encryption key file, the root certificates, and the signing certificates by either drag and dropping or browsing for new files. For details on each field of the JSON file, see */Documentation/KW45JsonDescription.pdf* provided with Over the Air Programming tool.

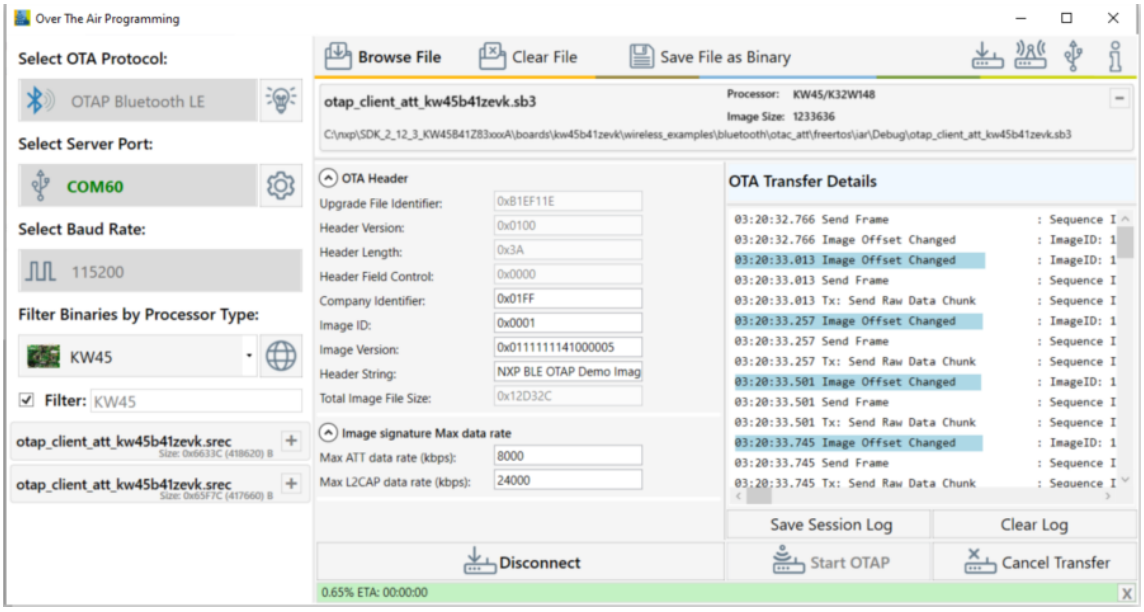
By default, the JSON is configured for the demo applications to run as shown in the figure below.



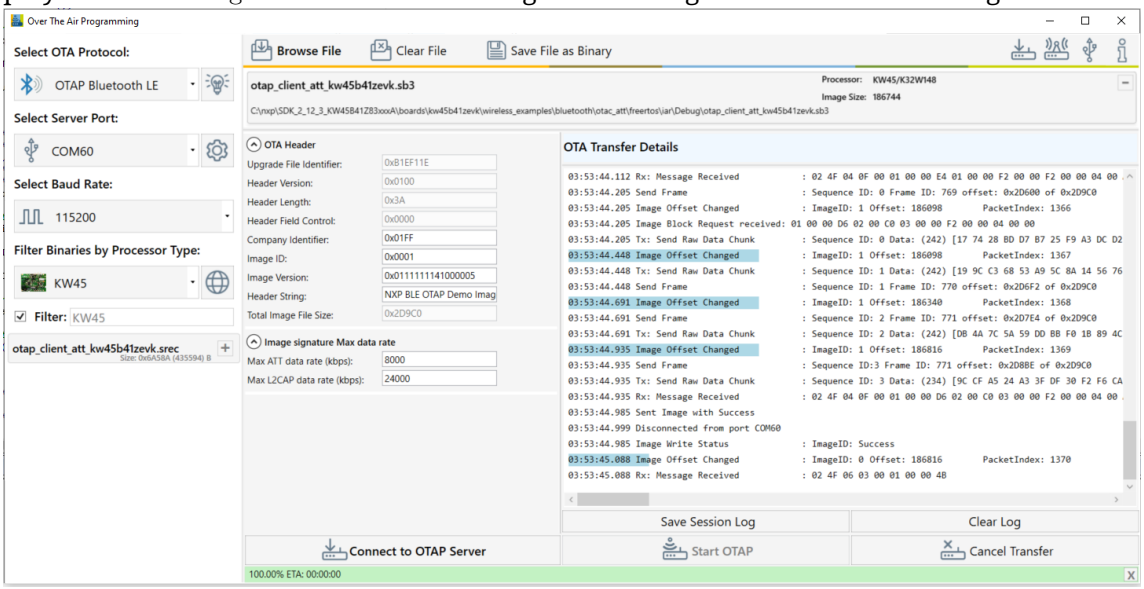
- After the .sb3 file is created, the "**Encryption Key**" and "**Authentication Key**" are presented. For the secured update to be successful, the destination board must have been provisioned with these keys through fuse burning, as described in the accompanying document. Depending on the board type, it can either be already provisioned by NXP (KW45\KW47\MCX-W71\MCX-W72 samples) or not provisioned (loose samples). See the figure below.

- The OTA Header configuration options from the "**OTA Header**" box are used by the application to build the **OTAP Image File**, which is sent over the air. The default values of

the OTA Header configuration work out of the box for the OTAP demo applications. For details about these configuration options, see the *Bluetooth LE Application Developer's Guide* document (*BLEADG*).



- After the image is loaded, go to the "**Select Server Port**" box, select the correct COM Port for the OTAP Server board. Also select the default baud rate of 115200 and press the "**Connect to OTAP Server**" button. A successful connection is displayed in the Message Log.
  - If the image is loaded before connecting to the OATP Server COM Port, then the OTAP Server of the application starts automatically.
  - If the connection to the COM Port is established before the image is loaded, then the "**Start OTAP**" button must be pressed to start the OTAP Server of the application. For details, see the figure below. .



- Before starting the image transfer process, the data rate must be configured for each transfer method (ATT or L2CAP CoC). The image chunks of a block are sent over the serial interface and over-the-air without waiting for confirmation. Data rate can significantly slow down if configuration is not done correctly and errors appear in the transfer process.

  The optimal data rate depends on multiple factors. Some of these factors are listed below:
  - Distance between boards
  - Type of antenna
  - Performance of the RF circuitry between the radio and antenna
  - Type and level of noise in the environment
  - Speed of the storage medium in which the image is saved on the OTAP Client
  - Serial driver delay between PC and the OTAP Server board If the data rate is too high, then the OTAP Client receives a new chunk before it can process the previous one. In such a case, it sends an "**Unexpected Chunk Sequence Number**" error and restarts the transfer of the current block from where it left off. If the channel is too noisy, the transmitter can be flooded and some chunks might not reach the client triggering a similar type of error. The default data rate values should work for most configurations.

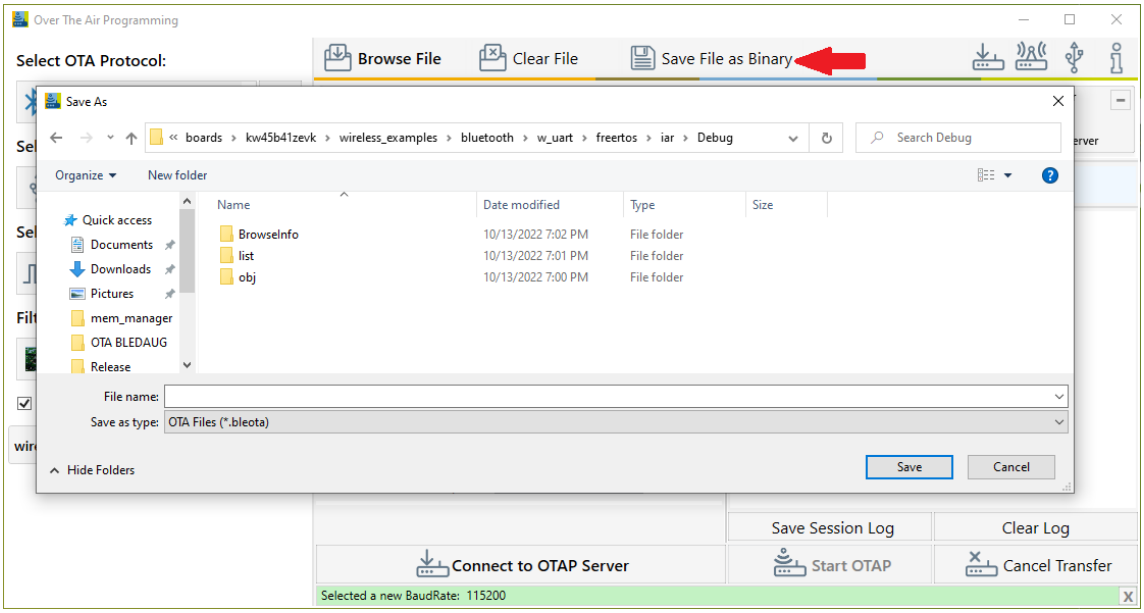
7. Start the embedded applications by pressing **ADVSW** first on the OTAP Client and then on the OTAP Server. The transfer progress and transfer-related messages and/or errors are shown in the application window. The duration of the transfer depends on the size of the image and the chosen data rate and transfer method. See the figure below.

8. After all the blocks are sent, the OTAP Client sends an Image Transfer Complete command to the OTAP Server. When the PC Application receives this command, it displays a Sent Image with Success message in the log window. See the figure below.

9. After the image transfer is complete, the OTAP Client triggers the bootloader and resets the MCU. The bootloader takes about 30 seconds to flash the image on the board. After this time frame, the MCU resets again and runs the new image.

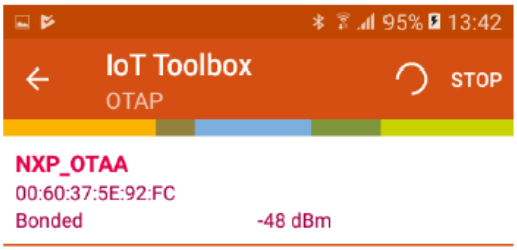
Parent topic: Over the Air Programming (OTAP)

Storage type selection OTAP Clients support both internal and external storage. By default, the applications come with internal storage enabled. To configure external storage, follow the steps bellow:

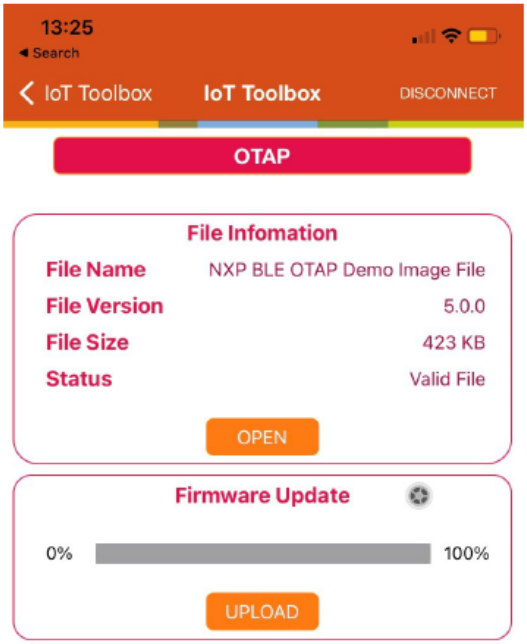


1. Set the gUseInternalStorageLink_d define to 0 in the project settings.
2. In app_preinclude.h, set the gAppOtaExternalStorage_c define to 1.

Usage with IoT Toolbox This is the list of requirements.

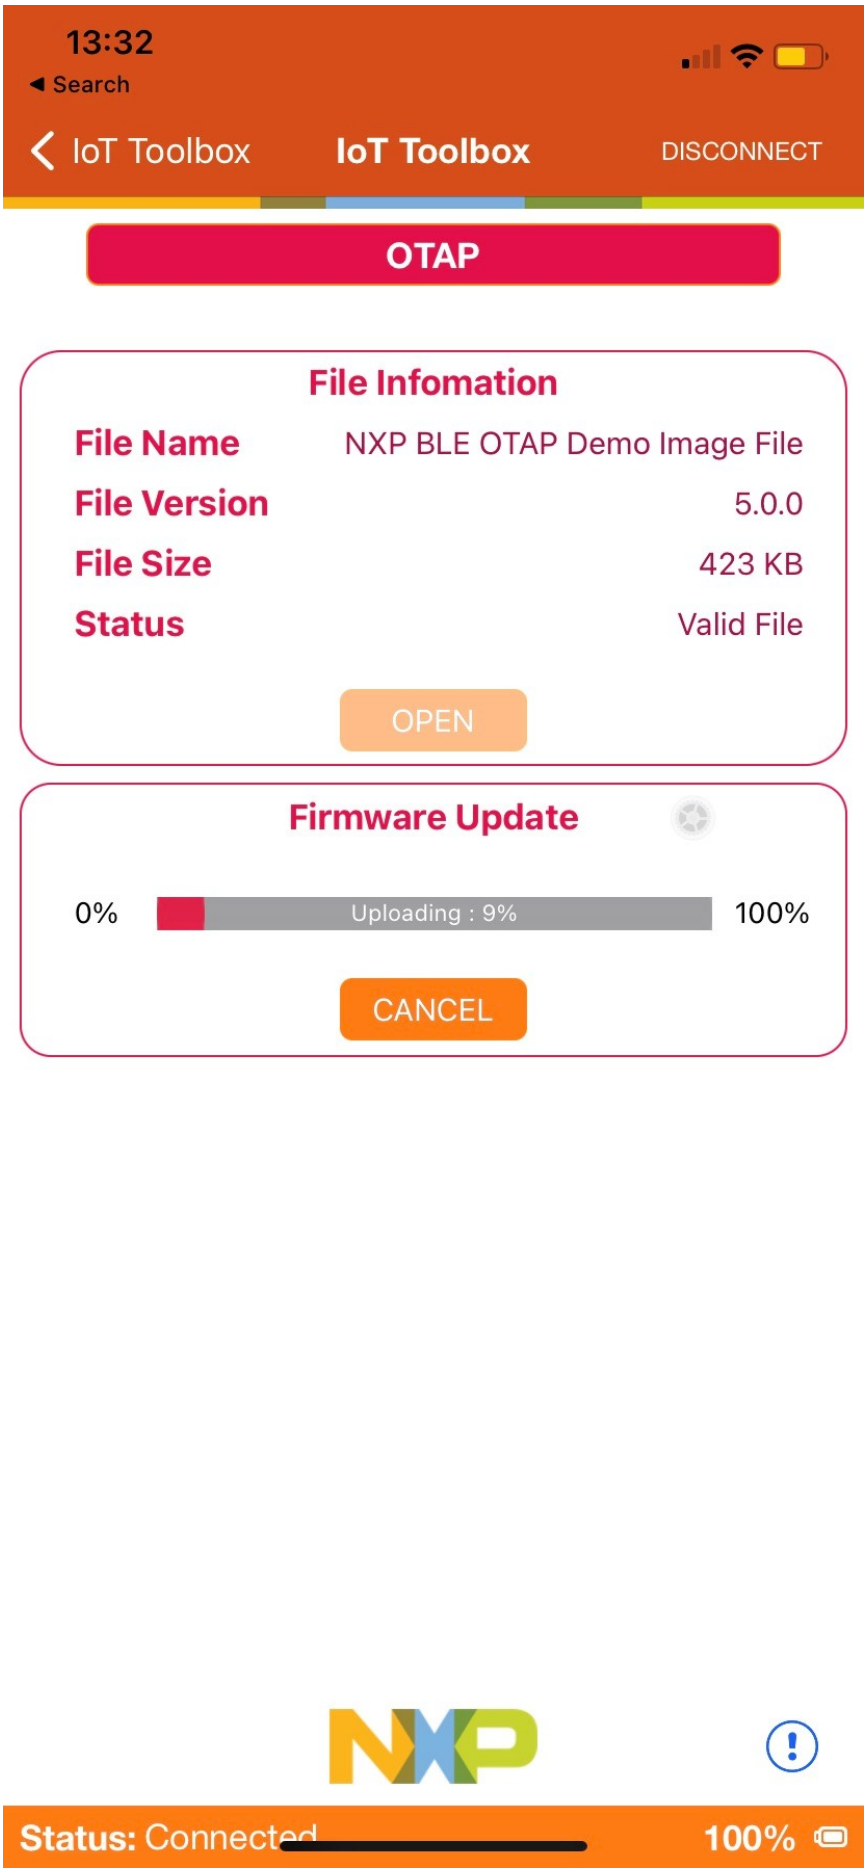


- **Mobile device** running **Android** platform or **iOS** with hardware and software supporting **Bluetooth 4.0 and later**.
- **Kinetis Bluetooth LE Toolbox** application – download from the specific application store for your device.



To run the application, perform the following steps:

1. Flash the OTAP Client ATT to either the KW45B41Z-EVK or the FRDM-MCXW71 platform. The Kinetis Bluetooth LE Toolbox only supports the ATT OTAP Client.
2. In order to send over the air in .bleota format, create the application. In order to load the image file into the Over the Air Programming application and create the .sb3 file, follow the instructions described in Usage with Over The Air Programming Tool. Once the .sb3 file is created, press the "**Save File as Binary**" button to create the .bleota file. See the figure below.



3. Start the **Kinetis Bluetooth LE Toolbox**application on your mobile device and start the **OTAP Tool**. The application starts scanning.
4. Press **ADVSW** on the board to start Advertising on the embedded OTAP Client application. The device should show up in the list of scanned devices. Touch the device in the scan list to connect to and the application performs service discovery and displays some information shown in the figure below.

5. Press the "**Open**" button and load the .bleota file to be sent over-the-air. Once the file is loaded, some information about it is displayed. Press the "**Upload**" button to start the image transfer process. A progress bar is shown while the image transfer is ongoing. The progress bar displays 100% update after a successful transfer, as shown in the figure below.

6. After the image transfer is complete, the OTAP Client triggers the bootloader and resets the MCU. The bootloader takes about 30 seconds to flash the image on the board. After this time passes, the MCU resets again and runs the new image.

Parent topic: Over the Air Programming (OTAP)

Parent topic:*Bluetooth LE stack and demo applications*

Wireless UART This section describes the implemented profiles and services, user interactions, and testing methods for the Wireless UART application.

Implemented profile and services The Wireless UART application implements both the GATT client and server for the custom Wireless UART profile and services.

- Wireless UART Service (UUID: 01ff0100-ba5e-f4ee-5ca1-eb1e5e4b1ce0)
- Battery Service v1.0
- Device Information Service v1.1

The Wireless UART service is a custom service that implements a custom writable ASCII Char characteristic (UUID: 01ff0101-ba5e-f4ee-5ca1-eb1e5e4b1ce0) that holds the character written by the peer device.

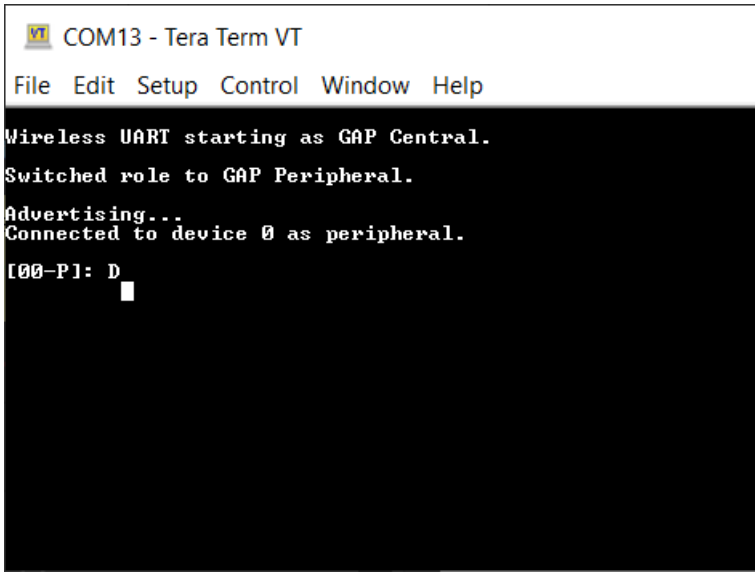
The application behaves at first as a GAP central node. It enters GAP Limited Discovery Procedure and searches for other Wireless UART devices to connect. To change the device role to GAP peripheral, use the ROLESW button. The device enters GAP General Discoverable Mode and waits for a GAP central node to connect.

Parent topic: Wireless UART

Supported platforms The following platforms support the Wireless UART application:

- KW45B41Z-EVK
- KW45B41Z-LOC
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- KW47-LOC
- FRDM-MCXW72
- MCX-W72-EVK
- MCXW72-LOC
- FRDM-MCXW23
- MCXW23-EVK

Parent topic: Wireless UART



User interface After flashing the board, the device is in idle mode (all LEDs flashing). To start scanning, press the **SCANSW** button. When in GAP Limited Discovery Procedure of GAP General Discoverable Mode, **CONNLED** is flashing. When the node connects to a peer device, **CONNLED** turns solid. To disconnect the node, hold the **SCANSW** button pressed for 2-3 seconds. The node then re-enters GAP Limited Discovery Procedure.

Parent topic: Wireless UART

Usage The application is built to work with another supported platform running the same example or with the Wireless UART from the IoT Toolbox application.

When testing with two boards, perform the following steps:

1. Open a serial port terminal and connect them to the two boards, in the same manner described in Testing devices. The start screen is blank after the board is reset.
2. The application starts as a GAP central. To switch the role to a GAP peripheral, press the role switch. Depending on the role, when pressing the **SCANSW**, the application starts either scanning or advertising.
3. As soon as the **CONNLED** turns solid on both devices, the user can start writing in one of the consoles. The text appears on the other terminal.
4. After creating a connection, the role (central or peripheral) is displayed on the console. The role switch can be pressed again before creating a new connection. See the figure below.

Tera Term – received text on Wireless UART

When testing with a single board and the IoT Toolbox, perform the following steps:

1. Open a serial port terminal and connect the board in the same manner described in Testing devices. The start screen is blank after the board is reset.
2. Press the role switch button to behave as a GAP peripheral and then press the **SCANSW** button to start advertising. The IoT Toolbox app can then connect. Select UART instead of Console and start typing, as shown in the Figure.

Parent topic: Wireless UART

Parent topic:*Bluetooth LE stack and demo applications*

Bluetooth LE Shell This section describes the functionality, user interactions, and testing methods for the Bluetooth LE Shell Application.

Implemented stack features The Bluetooth LE Shell Application implements a console application that allows the user to interact with a full feature Bluetooth Low Energy stack library. It implements All GAP roles and both GATT client and server. Enabling these roles can be done using shell commands.

Parent topic: Bluetooth LE Shell

Implemented profile and services The application implements a dynamic GATT database. The user can add services at runtime and also erase the database contents. The database is always populated with the GAP and GATT services. These services cannot be erased. The user can dynamically add the following services:

- Heart Rate Service (UUID: 0x180D)
- Battery Service (UUID: 0x180F)
- Device Information Service (UUID: 0x180A)
- Internet Support Profile Service (0x1820)

Parent topic: Bluetooth LE Shell

Supported platforms The following platforms support the Bluetooth LE Shell application:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK

Parent topic: Bluetooth LE Shell

User interface After flashing the board, the device is in idle mode. The interaction with the board is done entirely by using the shell commands via the serial communication terminal.

Parent topic: Bluetooth LE Shell

Usage The application is built to work with any other Bluetooth LE device. To showcase the functionality, two platforms are used in the following setup.

1. Open a serial port terminal and connect them to the two boards, in the same manner described in Testing devices. The start screen is displayed after the board is reset. All LEDs are flashing on both devices.
2. Configure one of the devices as a GAP peripheral and a Heart Rate server. Change name to HRS. Start advertising on this device.

```
BLE Shell>gap devicename HRS
--> GATTDB Event: Attribute Written
HRS>gap advdata 1 6
HRS>gap advdata 8 HRS
HRS>gap advstart
HRS>
--> GAP Event: Advertising parameters successfully set.
HRS>
--> GAP Event: Advertising data successfully set.
HRS>
--> GAP Event: Advertising state changed successfully!
HRS>gattdb addservice 0x180D
--> Heart Rate
- Heart Rate Measurement Value Handle: 14
```

3. Configure the other device as a GAP central. Change its name to ‘Collector’. Start scanning and connect to the HRS device by selecting the corresponding device index from the list of scanned devices. In the example below, the HRS device is device number 2. The number of

listed scanned devices can be controller through the mShellGapMaxScannedDevicesCount_c define in shell_gap.c.

```
BLE Shell>gap devicename Collector
--> GATTDB Event: Attribute Written
Collector>gap scanstart filter
--> GAP Event: Scan started.
Collector>
--> GAP Event: Found device 0 : 880F102F500E 0 dBm
--> GAP Event: Found device 1 : NXP_CSCS 00049F000006 0 dBm
--> GAP Event: Found device 2 : HRS 00049F0000FF 0 dBm
Collector>gap connect 2
--> GAP Event: Scan stopped.
Collector>
--> GAP Event: Connected to peer 0
```

4. Optionally, the devices can be paired (gAppUsePairing_d and gAppUseBonding_d must be set in app_preinclude.h). On the collector initiate the pairing.

```
Collector>gap pair 0
--> Pairing...
--> GAP Event: Link Encrypted
--> GAP Event: Device Paired
```

5. On the Collector, start service discovery. The device discovers the GAP, GATT, and Heart Rate services.

```
Collector>gatt discover 0 -all
--> Discovered primary services: 3
--> Generic Attribute Start Handle: 1 End Handle: 4
- Service Changed Value Handle: 3
- Client Characteristic Configuration Descriptor Handle: 4
--> Generic Access Start Handle: 5 End Handle: 11
- Device Name Value Handle: 7
- Appearance Value Handle: 9
- Peripheral Preferred Connection Parameters Value Handle: 11
--> Heart Rate Start Handle: 12 End Handle: 19
- Heart Rate Measurement Value Handle: 14
- Client Characteristic Configuration Descriptor Handle: 15
- Body Sensor Location Value Handle: 17
- Heart Rate Control Point Value Handle: 19
```

6. Configure the HRS to send notifications by writing the CCCD from the Collector. Send a GATT write command with value 1 to the CCCD handle discovered, 15.

```
Collector>gatt write 0 15 0x0001
--> GATT Event: Characteristic Value Written!
```

7. Send heart rate measurement notifications from the HRS device by using the value handle obtained after adding the service in the previous step.

```
HRS>gatt notify 0 14
```

8. A notification appears on the Collector console.

```
Collector>
--> GATT Event: Received Notification
Handle: 14
Value: B400
```

Extended advertising Use the Bluetooth LE Shell application to exercise the advertising extension features:

On the GAP Peripheral device:

1. Configure the extended advertising parameters. In the below example, the advertising type is set to connectable and includes TX power and the primary PHY is set to Coded PHY.
2. Configure the extended advertising data. The Bluetooth LE Shell applications has the feature to send for test, a large data payload. Use the extended advertisement default configuration (not call "gap extadvcfg"), pass the command "gap extadvdata" with no parameters and the default data is added. The length is configurable at compile time through SHELL_EXT_ADV_DATA_SIZE and the data pattern is SHELL_EXT_ADV_DATA_PATTERN. Start the default test with call for "gap extadvstart".

   The advertising data type is set to shortened local name (8) and the advertising data content is set to test_ext_adv_data.

   Note: Users must note that extended connectable advertising does not allow for chained advertising data. The data length must be limited to what can fit in a single AUX_ADV_IND PDU (251 bytes at maximum). This means that passing the gap extadvdata with no parameters and the default value of SHELL_EXT_ADV_DATA_SIZE (500 bytes) after having set the advertising type to connectable will result in an error when trying to start advertising.
3. Start extended advertising.

```
BLE Shell>gap extadvcfg -type 65 -phy1 3
BLE Shell>gap extadvdata 8 test_ext_adv_data
BLE Shell>gap extadvstart
--> GAP Event: Extended
Advertising parameters successfully set.
--> GAP Event:
Extended Advertising data successfully set.
--> GAP Event: Advertising state changed successfully!
```

4. **On the GAP Central device**

   Set the scanning parameters. The scanning PHY is set to match the advertising PHY, in this case Coded PHY.
5. Start scanning and filter duplicates.

```
BLE Shell>gap scancfg -phy 4
BLE Shell>gap scanstart filter
BLE Shell>
-> GAP Event: Scan started.
BLE Shell>
--> GAP Event: Found device 0 : 0060375BCEC6 -23 dBm
Advertising Extended Data:
test_ext_adv_data
```

6. Set the connection initiating PHYs corresponding to the primary PHY on which the advertising is performed.
7. Connect to the desired device in the scanned devices list.

```
BLE Shell>gap connectcfg -phy 4
--> Connection Parameters:
--> Connection Interval: 200 ms
--> Connection Latency: 0
--> Supervision Timeout: 32000 ms
--> Connecting PHYs: Coded
BLE Shell>gap connect 0
BLE Shell>
-> GAP Event: Scan stopped.
BLE Shell>
--> GAP Event: Connected to peer 0
```

Parent topic: Usage

RSSI Monitor RSSI Monitor is an application that allows monitoring the RSSI of a remote peer on advertising or connection channel. The GAP peripheral device can modify the output TX power on both advertising and connection channels.

1. **On GAP peripheral device**

   Set the primary advertising PHY to Coded PHY. Start advertising and read the address. Set the TX power in dBm to a value less than 20 dBm.

```
BLE Shell>gap address
BLE Shell>
--> GAP Event: Public Address Read:C4603770BCC5
BLE Shell>gap extadvcfg -phy1 3
BLE Shell>gap extadvstart
BLE Shell>
--> GAP Event: Extended Advertising parameters successfully set.
BLE Shell>
--> GAP Event: Extended Advertising data successfully set.
BLE Shell>
--> GAP Event: Advertising state changed successfully!
BLE Shell>gap txpower adv 0
BLE Shell>
--> GAP Event: Success!
```

2. **On GAP Central device**

   Set the scanning PHY to Coded PHY. Start monitoring the RSSI on advertising Channel using the address of the Peripheral device. Scanning starts automatically, if it is not previously enabled.

```
BLE Shell>gap scancfg -phy 4
BLE Shell>gap rssimonitor C4603770BCC5--> Reading RSSI on advertising channel:
BLE Shell>
-> GAP Event: Scan started.
BLE Shell>
 RSSI: -27 dBm
 RSSI: -27 dBm
 RSSI: -27 dBm
 RSSI: -27 dBm
 RSSI: -27 dBm
 RSSI: -29 dBm
```

   In the below example, the RSSI in monitored on a connection channel. On GAP Peripheral, start advertising in connectable mode on Coded PHY and adjust the TX power level.

```
BLE Shell>gap extadvcfg -type 65 -phy1 3
BLE Shell>gap extadvdata 8 rssimonitortest
BLE Shell>gap extadvstart
BLE Shell>
--> GAP Event: Extended Advertising parameters successfully set.
BLE Shell>
--> GAP Event: Extended Advertising data successfully set.
BLE Shell>
--> GAP Event: Advertising state changed successfully!
BLE Shell>
--> GAP Event: Connected to peer 0
BLE Shell>
--> GAP Event: Advertising stopped!
BLE Shell>gap txpower conn 10
```

(continues on next page)

(continued from previous page)

```
BLE Shell>
--> GAP Event: Success!
```

On the GAP Central device, start scanning on the Coded PHY. Update the connection PHY also to Coded PHY, then connect to the remote device and monitor continuously the RSSI on the connection channel.

```
BLE Shell>gap scancfg -phy 4
BLE Shell>gap connectcfg -phy 4
-->  Connection Parameters:
    -->  Connection Interval: 200 ms
    -->  Connection Latency: 0
    -->  Supervision Timeout: 32000 ms
    -->  Connecting PHYs: Coded
BLE Shell>gap scanstart filter
BLE Shell>
->  GAP Event: Scan started.
BLE Shell>
-->  GAP Event: Found device 0 : C4603770BCC5 -21 dBm
 Advertising Extended Data:
rssimonitortest
gap connect 0
BLE Shell>
->  GAP Event: Scan stopped.
BLE Shell>
-->  GAP Event: Connected to peer 0
BLE Shell>gap rssimonitor 0 -c
-->  Reading RSSI from connected device:
BLE Shell>
 RSSI: -22 dBm
 RSSI: -23 dBm
 RSSI: -21 dBm
 RSSI: -22 dBm
 RSSI: -22 dBm
BLE Shell>gap rssistop
```

3. Update the PHY preference and continue monitoring the RSSI. For coded PHY, the coding scheme can be configured between S2 and S8 (500 kbit/s and 125 kbit/s).

```
BLE Shell>gap phy 0 -tx 4 -rx 4 -o 1
BLE Shell>
--> GAP Event: Phy update complete with peer 0
--> TxPhy: Coded
--> RxPhy: Coded

BLE Shell>gap phy 0 -tx 2 -rx 2
BLE Shell>
--> GAP Event: Phy update complete with peer 0
--> TxPhy: 2M
--> RxPhy: 2M

BLE Shell>gap rssimonitor 0 -c
--> Reading RSSI from connected device:
BLE Shell>
RSSI: -23 dBm
RSSI: -23 dBm
RSSI: -21 dBm
RSSI: -21 dBm
--> GAP Event: Phy update complete with peer 0
--> TxPhy: Coded
--> RxPhy: Coded
```

(continues on next page)

(continued from previous page)

```
BLE Shell>
RSSI: -22 dBm
RSSI: -21 dBm
RSSI: -22 dBm
RSSI: -23 dBm
RSSI: -23 dBm
--> GAP Event: Phy update complete with peer 0
--> TxPhy: 2M
--> RxPhy: 2M
BLE Shell>
RSSI: -22 dBm
RSSI: -21 dBm
RSSI: -21 dBm
RSSI: -20 dBm
```

Parent topic: Usage

Parent topic: Bluetooth LE Shell

Throughput feature The Bluetooth LE Shell application also has a throughput test feature that can be used to test different combinations of the parameters (connection interval, payload size, and packet count) to determine the best data-rate.

This feature requires two devices:

- GAP Peripheral: transmits the test packets
- GAP Central: receives the packets and displays a report

All throughput-related commands are grouped under the **thrput** keyword:

- thrput setparam: configures connection interval, packet count and payload size.
- thrput start tx: configures the device as a GAP Peripheral and starts advertising. Once the receiving device is connected, the packet transmission begins. The packet size and count can also be specified (-s<size_value>-c<count_value>).
- thrput start rx: configures the device as a GAP Central and starts scanning. Once a transmitter device is found, it connects to it and waits for the test to begin. The connection interval can also be configured (-ci<value>).
- thrput stop: stops the test and disconnects the devices.

Once a connection is established between the devices and initial throughput test is complete, one can start a new throughput transmission test with a new set of parameters (packet size / count).

The receiving device generates the report if no packets are received for more than three consecutive connection events.

The default configuration of the throughput test is the following:

- Packet count: 1000
- Payload size: 20 bytes

Connection interval (min, max): 160, 160 (200 ms)

The example of a test report is shown below:

```
BLE Shell>thrput start tx
BLE Shell>
-->  GAP Event: Advertising parameters successfully set.
BLE Shell>
```

(continues on next page)

(continued from previous page)

Parent topic: Bluetooth LE Shell

Decision-Based Advertising Filtering (DBAF) feature The Bluetooth LE Shell application also supports the Decision-Based Advertising Filtering (DBAF) feature, which can be enabled by performing the following steps:

- Flash the NBU: for KW45B41Z-EVK/FRDM-MCXW71 flash the experimental NBU found in middleware/wireless/ble_controller/bin/experimental; for KW47-EVK/MCX-W72-EVK/FRDM-MCXW72 flash the all-purpose NBU found in middleware/wireless/ble_controller/bin.
- Update the application project so that it uses the experimental Bluetooth LE Host library: middleware/wireless/bluetooth/host/lib_exp/lib_ble_OPT_host_cm33_iar.a
- In app_preinclude.h file, set BLE_SHELL_DBAF_SUPPORT to 1.

This feature requires two devices:

- GAP Peripheral: transmits decision PDUs (ADV_DECISION_IND).
- GAP Central: scans for decision PDUs and handles filtering policies.

To showcase the functionality, two platforms are used in the following setup.

Steps to perform on the GAP Peripheral device:

1. Configure the extended advertising parameters to use decision PDUs. In the below example, the advertising type is set to connectable and includes TX power, uses decision PDUs and includes AdvA in the decision PDU. The primary PHY is set to Coded PHY.

2. Configure the extended advertising data using the gap extadvdecdata command. The resolvable tag and/or arbitrary data can be set using the parameters available.
3. Start extended advertising.

```
BLE Shell>gap extadvcfg -phy1 3 -type 449
BLE Shell>gap extadvdecdata -key 112233445566778899AABBCCDDEEFF00 -prand 5AC317 -decdata␣
↪6362 -datalen 2 -restag 0
BLE Shell>gap extadvstart
BLE Shell>
--> GAP Event: Extended Advertising parameters successfully set.
BLE Shell>
--> GAP Event: Extended Advertising data successfully set.
BLE Shell>
--> GAP Event: Extended Advertising Decision Data Setup Complete.
BLE Shell>
--> GAP Event: Advertising state changed successfully!
BLE Shell>
```

Steps to perform on the GAP Central device:

1. Set the scanning parameters to scan only decision PDUs. The scanning PHY is set to match the advertising PHY, in this case Coded PHY.
2. Set the connection parameters to use only decision PDUs and the connection initiating PHYs corresponding to the primary PHY on which the advertising is performed.

```
BLE Shell>gap scancfg -phy 4 -filter 12
BLE Shell>gap connectcfg -phy 4 -filter 2
--> Connection Parameters:
 --> Connection Interval: 200 ms
 --> Connection Latency: 0
 --> Supervision Timeout: 32000 ms
 --> Connecting PHYs: Coded
 --> Connection Filter Policy: 2
BLE Shell>
```

3. Add decision instructions using the gap adddecinstr command. A maximum of gMaxNumDecisionInstructions_c instructions can be added. If the set of instructions must be changed, the gap deldecinstr command deletes all current instructions.

```
BLE Shell>gap adddecinstr -group 1 -field 0 -criteria 1 -restagkey␣
↪112233445566778899AABBCCDDEEFF00
BLE Shell>gap adddecinstr -group 1 -field 6 -criteria 1 -advmode 6
BLE Shell>gap adddecinstr -group 0 -field 24 -criteria 1 -arbmask 00000000ffffff
BLE Shell>gap adddecinstr -group 0 -field 9 -criteria 1 -advacheck 2 -add1type 0 -add1 a6fb0d376000 -
↪add2type 0 -add2 a5fb0d376000
BLE Shell>gap adddecinstr -group 0 -field 7 -criteria 1 -rssimin -80 -rssimax 0
BLE Shell>gap adddecinstr -group 0 -field 8 -criteria 5 -lossmin 0 -lossmax 50
BLE Shell>
```

4. Set the decision instructions using the gap setdecinstr command. The instructions are used when listening for advertisements containing decision PDUs.
5. Start scanning and filter duplicates.
6. Connect to the desired device in the scanned devices list.

```
BLE Shell>gap setdecinstr
BLE Shell>
--> GAP Event: Decision Instructions Setup Complete.
BLE Shell>gap scanstart filter
BLE Shell>
-> GAP Event: Scan started.
```

(continues on next page)

(continued from previous page)

```
BLE Shell>
--> GAP Event: Found device 0 : C4603770BCC5 -23 dBm
 Advertising Extended Data:
gap connect 0
BLE Shell>
-> GAP Event: Scan stopped.
BLE Shell>
--> GAP Event: Connected to peer 0
BLE Shell>
```

Parent topic: Bluetooth LE Shell

Periodic Advertising with Responses (PAwR) feature The Bluetooth LE Shell application also supports the Periodic Advertising with Responses feature, which can be enabled by performing the following steps:

- Flash the NBU: for KW45B41Z-EVK/FRDM-MCXW71 flash the experimental NBU found in middleware/wireless/ble_controller/bin/experimental; for KW47-EVK/MCX-W72-EVK/FRDM-MCXW72 flash the all-purpose NBU found in middleware/wireless/ble_controller/bin.
- Update the application project so that it uses the experimental Bluetooth LE Host library, middleware/wireless/bluetooth/host/lib_exp/lib_ble_OPT_host_cm33_iar.a.
- In app_preinclude.h file, set BLE_SHELL_PAWR_SUPPORT to 1.

This feature requires two (or more) devices:

- GAP Broadcaster: transmits advertising PDUs at a fixed interval. (AUX_SYNC_SUBEVENT_IND)
- GAP Observer (one or more): scans for advertising PDUs and synchronizes with the advertising train. Sends responses PDUs in the synced subevents. (AUX_SYNC_SUBEVENT_RSP)

To showcase the functionality, two platforms are used in the following setup.

Steps to perform on the GAP Broadcaster device:

1. Configure the periodic advertising parameters. In the below example, a set of implicit values are used. There are 2 subevents per interval, each interval repeating at 1 second. There are 4 response slots configured per subevent, with the first response slot starting at 125ms from the advertising packet.

```
BLE Shell>gap periodiccfg

--> Periodic Advertising Parameters:
    --> Periodic Advertising Handle: 1
    --> Periodic Advertising Interval: 2000 ms
    --> Number of subevents: 2
    --> Interval between subevents: 156.25 ms
    --> Time between the advertising packet in a subevent and the first response slot: 125.0 ms
    --> Time between response slots: 1.250 ms
    --> Number of response slots: 4
BLE Shell>
--> GAP Event: Periodic Advertising parameters successfully set.
```

   Alternatively, the command does accept all the mentioned parameters to be changed. The below command can be used to configure the exact same values.

```
BLE Shell>gap periodiccfg -numsubevents 2 -subint 125 -rspslotdelay 100 -rspslotspace 10 -numrspslot 4
BLE Shell>
--> GAP Event: Periodic Advertising parameters successfully set.
```

2. Configure the subevent data on the advertiser for each subevent. Each instance of the gap periodicsubeventdata command sets each subevent data for the configured number of subevents. In this used example, the first command sets the data for the first subevent, the second command sets the data for the second subevent. The upper limit is the lowest of the following: SHELL_PER_ADV_MAX_NUM_SUBEVENTS from app_preinclude.h or the number of subevents set using gap periodiccfg.

```
BLE Shell>gap periodicsubeventdata 255 696E666F31
BLE Shell>gap periodicsubeventdata 255 696E666F32
```

When the last subevent data is set, any succeeding command will erase the previously set data for all subevents, and the data in the ongoing command will be set in the first subevent.

Alternatively, the command accepts more advertising data structures for one subevent, up to SHELL_EXT_ADV_DATA_MAX_AD_STRUCTURES.

```
BLE Shell>gap periodicsubeventdata 27 01CAFECAFECAFE 255 696E666F31
```

To manually clear the data set for all the currently set subevents, you may issue the following command:

```
BLE Shell>gap periodicsubeventdata -erase
```

3. Start extended advertising.

```
BLE Shell>gap extadvstart
BLE Shell>
-->  GAP Event: Extended Advertising parameters successfully set.

BLE Shell>
-->  GAP Event: Extended Advertising data successfully set.

BLE Shell>
-->  GAP Event: Advertising state changed successfully!
```

4. Start periodic advertising.

```
BLE Shell>gap periodicstart
BLE Shell>Periodic Advertising state changed successfully!
```

Steps to perform on the GAP Observer device:

1. Start scanning using the gap scanstart command. Optionally you can modify the scan parameters using the gap scancfg command.

```
BLE Shell>gap scanstart
BLE Shell>
->  GAP Event: Scan started.
```

2. Issue a periodic sync command with the target address of the Broadcaster device that is periodic advertising. You can use the gap address command on the Broadcaster to obtain the address.

```
BLE Shell>gap periodicsync -peer 006037A55E86
```

When the sync is established, events will be printed at the console.

```
-->  GAP Event: Periodic Advertising Sync Established
-->  GAP Event: Periodic V2 Device Scanned
       Event Counter: 8
       Subevent Synced: 0
       RSSI: -38 dBm
       Advertising Data: info1
```

3. Synchronize the Observer device with the subevents needed. For this example, we will synchronize the Observer with both subevents using the following command. Implicitly, the Observer synchronizes to subevent 0.

```
BLE Shell>gap periodicsyncsubevent -peradvproperties 0 -numsubevents 2 -subevents 0x00,0x01
...
BLE Shell>Set Sync Subevent command successfully completed.
```

After this, GAP Events of type Periodic V2 Device Scanned should be displayed in the console for each of the subevents synchronized.

```
--> GAP Event: Periodic V2 Device Scanned
      Event Counter: 169
      Subevent Synced: 0
      RSSI: -34 dBm
      Advertising Data: info1
--> GAP Event: Periodic V2 Device Scanned
      Event Counter: 169
      Subevent Synced: 1
      RSSI: -38 dBm
      Advertising Data: info2
```

4. The last step to have a complete exchange of data is to set the response(s) on the Observer device. The next 2 commands will set the data for the 2 subevents synced at the previous step.

```
BLE Shell>gap periodicresponsedata -responsesubevent 0 -responseslot 0 -data 255␣
↪6465766936531696E666F31
BLE Shell>gap periodicresponsedata -responsesubevent 1 -responseslot 0 -data 255␣
↪6465766936531696E666F32
```

The -responsesubevent parameter indicates the subevent the data is set for. The -responseslot parameter indicates the response slot the data is sent at this value should be within the range 0 to the number of response slots set at periodiccfg.

To scale the demo to use more Observer devices, repeat steps 1-3 for each of the added device. Also use example at step 4, with the adaptation of the -responseslot according to the device index. The demo is designed to have a new device for each of the response slots available. Also, change the data to reflect the response of the extra device.

Note: *The* -data *parameter must be the last of the* periodicresponsedata *command as it can contain a volatile number of advertising data structures.*

Alternatively, the command may contain additional advertising data structures.

```
BLE Shell>gap periodicresponsedata -responsesubevent 0 -responseslot 0 -data 27␣
↪01CAFECAFECAFE 255 6465766936531696E666F31
BLE Shell>gap periodicresponsedata -responsesubevent 1 -responseslot 0 -data 27␣
↪01CAFECAFECAFE 255 6465766936531696E666F32
```

To manually clear the data set for all the currently set subevents, you may issue the following command:

```
BLE Shell>gap periodicresponsedata -erase
```

Initiate a connection from PAwR

PAwR feature allows for connection initiation from the Broadcaster device. To do this, the devices have to be synchronized. The minimum steps required for this are steps 1, 3, 4 on the GAP Broadcaster device and steps 1, 2, GAP Observer device.

After performing the mentioned steps, the Broadcaster device must issue the following command:

```
BLE Shell>gap connectpawr -subevent 0 -peer 00603728063E -peeraddrtype 0
```

Upon successful connection the following message will be displayed.

```
--> GAP Event: Connected to peer 0
```

Parent topic: Bluetooth LE Shell

Parent topic:*Bluetooth LE stack and demo applications*

Hybrid (Dual-mode) Bluetooth Low Energy and Generic FSK The Hybrid (Dual-mode) Bluetooth Low Energy and Generic FSK application demonstrates Generic FSK transmission/reception and Bluetooth advertising/scanning/multiple connections coexistence.

The Bluetooth LE part of this demo implements a modified version of the Wireless UART demo application, capable of multiple Bluetooth LE connections.

Based on the Hardware link-layer implementation, the Bluetooth Low Energy has a higher priority than the Generic FSK protocol and as the effect, the Generic FSK communication is executed during the Idle states (inactive periods) of the Bluetooth LE. The coexistence of the two protocols is handled internally at the Controller level.

The Bluetooth LE part of the application behaves at first as a GAP central node. It enters GAP Limited Discovery Procedure and searches for other Wireless UART devices to connect. To change the device role to GAP peripheral, use the **ROLESW** button. The device enters GAP General Discoverable Mode and waits for a GAP central node to connect.

The Generic FSK part of the application can either enter in the receive state by double clicking the **SCANSW** button or it can start the periodic transmit by long pressing the **ROLESW** button. It cannot enter in both states at the same time.

The Generic FSK has lower priority than the Bluetooth LE. Therefore, any ongoing Generic FSK receive is paused by the Controller when Bluetooth LE activity is ongoing. The reception is automatically resumed by the Controller when there is no Bluetooth LE activity.

When using Generic FSK, packet loss should be expected. The Generic FSK communication does not offer an acknowledgement mechanism to guarantee success for packet transmission, therefore this communication method does not offer reliability. If the user wants to improve reliability, packet repetition may be used, or the user may implement a custom protocol at application level.

The first Generic FSK transmit command is buffered if there is continuous Bluetooth LE activity (for example, for continuous Bluetooth LE scanning). Any succeeding Generic FSK transmit command indicates failure in the command line interface, if the initial buffered transmit command was not sent yet.

This section describes the implemented profiles and services, user interactions, and testing methods for the Hybrid (Dual-Mode) Bluetooth Low Energy and Generic FSK application.

Implemented profile and services The Hybrid (Dual-Mode) Bluetooth Low Energy and Generic FSK application implements the GATT client and server for the custom Wireless UART profile and services. It also acts as a Generic FSK transmitter/receiver, repeating a custom packet, at a fixed periodic interval. It uses a predefined identifier, isolated to the address used in the Bluetooth LE protocol of the demo.

- Wireless UART Service (UUID: 01ff0100-ba5e-f4ee-5ca1-eb1e5e4b1ce0)
- Battery Service v1.0
- Device Information Service v1.1

The Wireless UART service is a custom service that implements a custom writable ASCII Char characteristic (UUID: 01ff0101-ba5e-f4ee-5ca1-eb1e5e4b1ce0) that holds the character written by the peer device.

The application is ready to start either Bluetooth LE scanning for Wireless UART Service, Bluetooth LE advertising Wireless UART Service, Generic FSK periodic transmit of a custom packet or Generic FSK receive, in the available slots not used by the Bluetooth LE protocol.

Parent topic: Hybrid (Dual-mode) Bluetooth Low Energy and Generic FSK

Supported platforms The following platforms support the Hybrid (dual-mode) Bluetooth Low Energy and Generic FSK application:

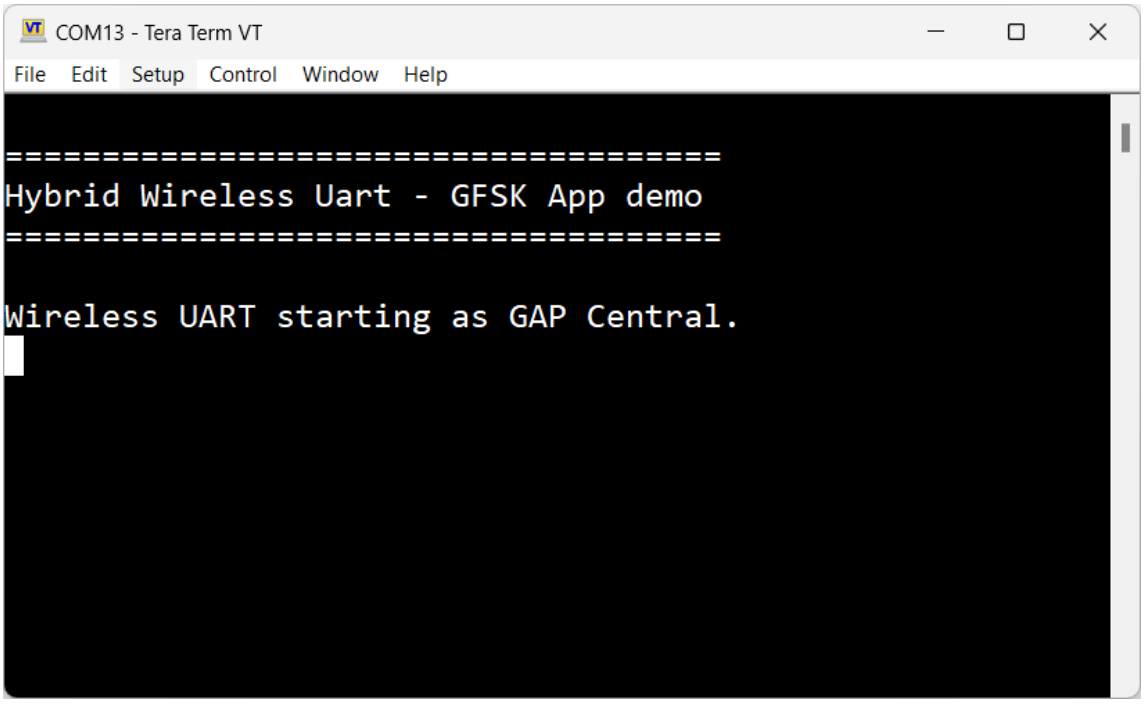
- KW45B41Z-EVK
- KW45B41Z-LOC
- KW47-EVK
- KW47-LOC

Parent topic: Hybrid (Dual-mode) Bluetooth Low Energy and Generic FSK

User interface After flashing the board, the device is in idle mode (all LEDs flashing). To start Bluetooth LE scanning, press the **SCANSW** button. When in GAP Limited Discovery Procedure of GAP General Discoverable Mode, **CONNLED** is flashing. When the node connects to a peer device, **CONNLED** turns solid. To disconnect the node, hold the **SCANSW** button pressed for 2-3 seconds. The node then re-enters GAP Limited Discovery Procedure.

To start Generic FSK receiving, double click the **SCANSW** button and the device starts receiving packets on the same channel as the Bluetooth LE channel 37, with the network address defined in gGenFSK_NetworkAddress_c. The receiver only prints the packets that have the predefined identifier at gGenFSK_Identifier_c. To stop Generic FSK reception, double click the **ROLESW** button.

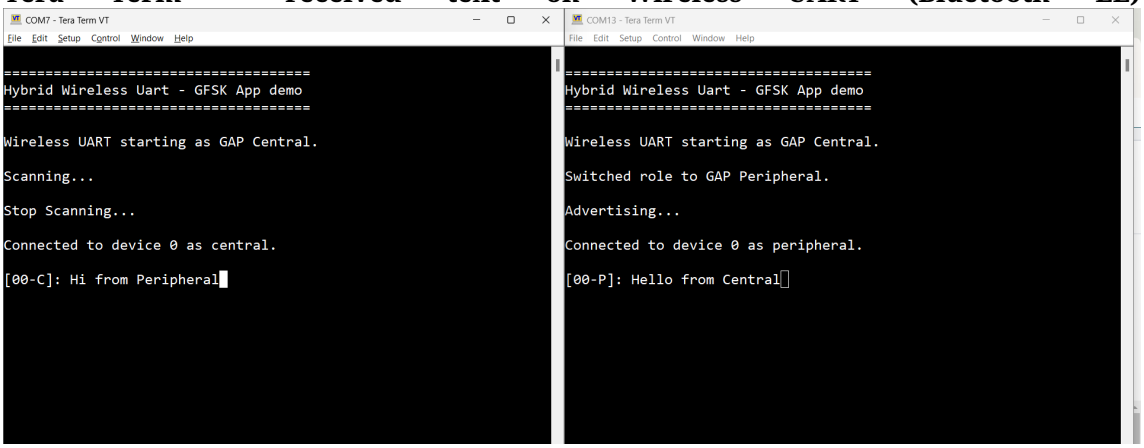
On a different device, start Generic FSK transmit by long pressing the **ROLESW** button. To stop the periodic Generic FSK transmit, long press again the **ROLESW** button, if the transmit procedure is ongoing. The long press **ROLESW** acts as a toggle for the transmit.



Parent topic: Hybrid (Dual-mode) Bluetooth Low Energy and Generic FSK

Usage The application is built to work with another supported platform running the same example. When testing with two boards, perform the following steps:

Case 1 (Bluetooth LE)

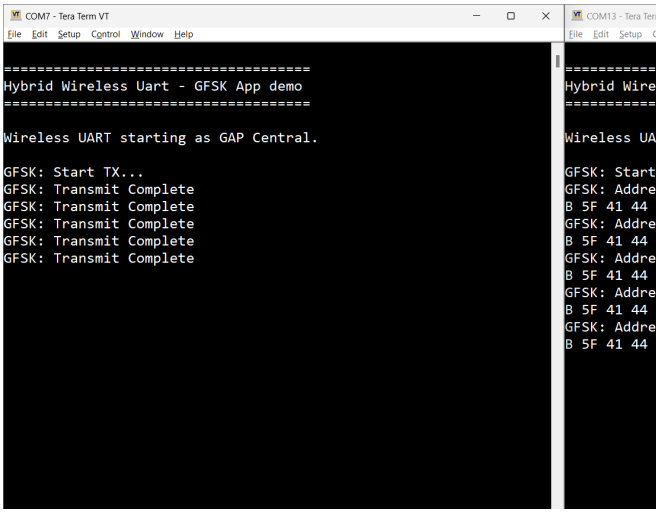


1. Open a serial port terminal and connect to the two boards, in the same manner described in Testing devices. The figure below displays the start screen after the board is reset.

   Tera Term – Hybrid Wireless UART (Bluetooth LE) - Generic FSK start screen

2. The application starts as a GAP central. To switch the role to a GAP peripheral, press the **ROLESW** button. Depending on the role, when pressing the **SCANSW** button, the application starts either scanning or advertising.
3. As soon as the **CONNLED** turns solid on both devices, the user can start writing in one of the consoles. The text appears on the other terminal.
4. After creating a connection, the role (central or peripheral) is displayed on the console. The role switch can be pressed again before creating a new connection. An output example can be observed in the figure below.

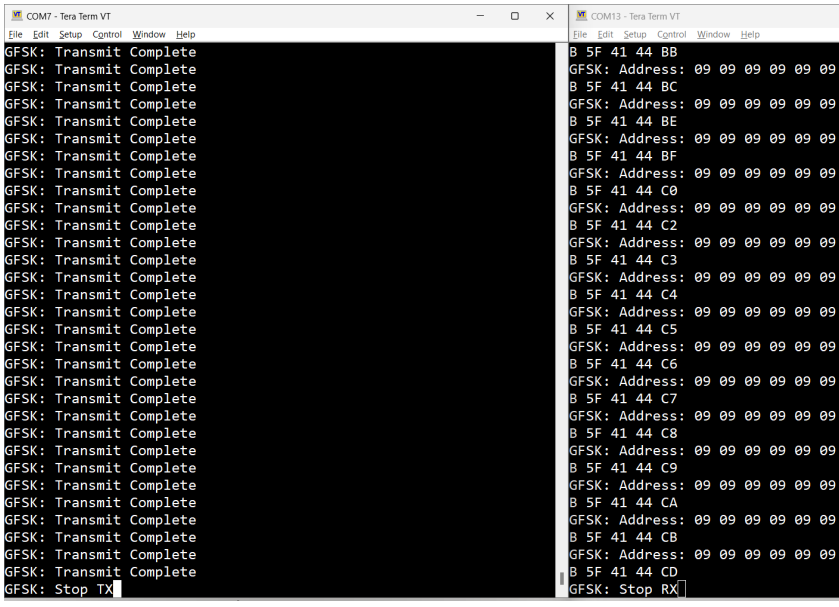
Tera Term – received text on Wireless UART (Bluetooth LE)



Parent topic: Usage

Case 2 (Generic FSK) When operating the Generic FSK mode, the following steps should be followed.

1. Open a serial port terminal and connect to the two boards, in the same manner described in Testing devices. The start screen after the board is reset is the same as in Figure.
2. The Generic FSK communication direction is not preset. To start receiving, double click the **SCANSW** button on one board. Then, the device starts receiving packets on the same channel as the Bluetooth LE channel 37.



3. To start transmitting, long press the **ROLESW** button on the other board. The transmitting device uses an identifier known by the receiver and its packets are displayed in the CLI as shown in Figure:

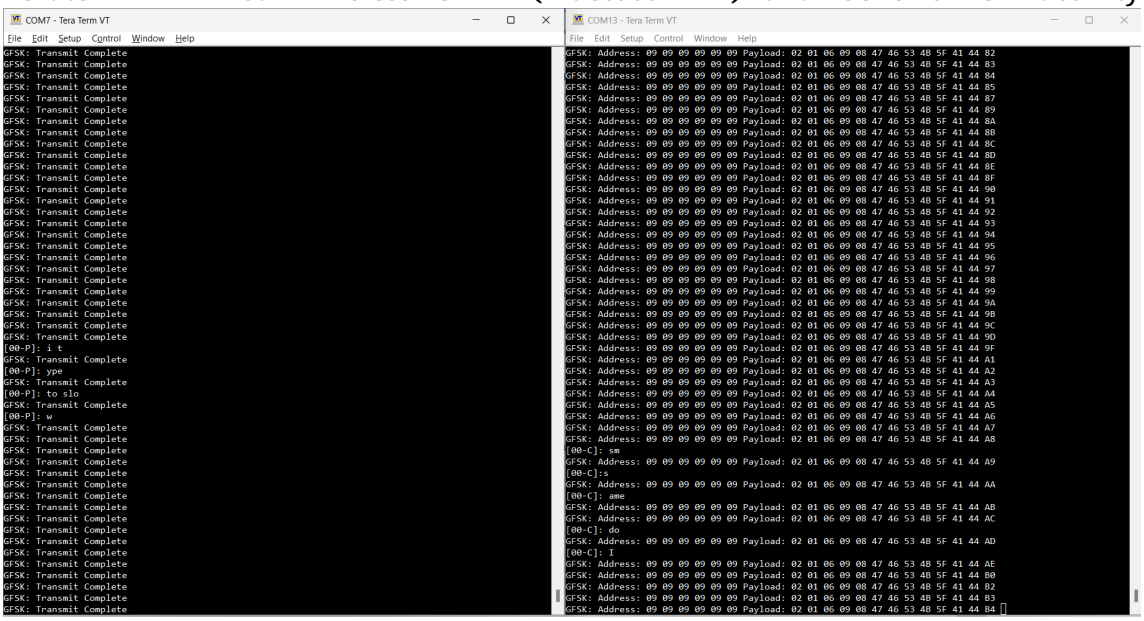
Teraterm – packet transmit/receive on Generic FSK

4. To stop Generic FSK reception, double click the **ROLESW** button.
5. To stop the periodic Generic FSK transmit operation, long press the **ROLESW** button again, if the transmit procedure is ongoing. The long press of the **ROLESW** button acts as a toggle for the transmit. At this point, both devices can reverse the direction of communication by following the exact same steps.

   See Figure.

Tera Term – stop Generic FSK activity

Parent topic: Usage



Case 3 (Dual-mode) The application is ready to combine both scenarios. It can either:

- Establish a Bluetooth LE connection and perform Generic FSK activity.
- During Generic FSK activity, the Bluetooth LE connection can be established and the Controller pauses receiving or announcing the discarded Generic FSK transmissions. This activity is resumed after the Bluetooth LE activity is finished.

To run the Dual-mode scenario, follow the steps below:

1. Establish a Bluetooth LE connection as described in Case 1 (Bluetooth LE).
2. Start Generic FSK activity as described in Case 2 (Generic FSK), independent of the Bluetooth LE roles chosen in Case 1.
3. Start typing in either of the terminals. As seen in Figure, the Bluetooth LE activity is prioritized. In this step, characters are printed in the peer's terminal and Generic FSK continues in the available slots, not used by the Bluetooth LE link.

Teraterm – Mixed Wireless UART (Bluetooth LE) and Generic FSK activity

Parent topic: Usage

Parent topic: Hybrid (Dual-mode) Bluetooth Low Energy and Generic FSK

Customization Use the steps below to change the default settings of this demo.

For Bluetooth LE, the default advertising config (gAdvParams) parameter is found in the app_config.c file. Also, the scanning parameters (gScanParams) can be found in this file.

The maximum number of connections supported by the Bluetooth LE, for this application, is defined in the app_preinclude.h file, with the macro name gAppMaxConnections_c.

Note: The Generic FSK protocol is active during the inactive periods of the Bluetooth LE protocol. The demo is currently configured to have the scan window equal to the scan interval to make the user aware of this, but this can be changed.

For Generic FSK, the following defines of interest can be found in genfsk_app.h, described below:

Name	Description
gGen-FSK_Netwc	This is the network address used for the Generic FSK, in the transmitter payload. It is implicitly set to the 0x8E89BED6, but this can be reconfigured. Ensure that it is also changed on the receiver in the hybrid_gfsk.c controller file.
gGen-FSK_H0Val	H0 value is used in the header.
gGen-FSK_Identi	This is the identifier used by the transmitter to be filtered at the receiver. The current implementation filters the Generic FSK packets received, based on this define.
gGenF-skApp_TxIı	This is the interval the transmitter will repeat the transmission of a packet. It is set in milliseconds.

Files of interest

The demo can be found in the w_uart_genfsk from the available examples.

The demo is based on the basic Wireless UART with the addition of some Generic FSK files required for working in dual-mode, described below.

File name	Description
genfsk_app.c	Application common module. Handles the HCI commands and events for the Generic FSK. Sends the events to the application.
genfsk_app.h	Application common module. Exposes public functions.
hybrid_gfsk.c	Controller common module. Handles initialization of Generic FSK.
hybrid_gfsk.h	Controller common module. Exposes public functions.

Parent topic: Hybrid (Dual-mode) Bluetooth Low Energy and Generic FSK

Parent topic:*Bluetooth LE stack and demo applications*

Wireless UART Host This section describes the implemented profiles and services, user interactions, and testing methods for the Wireless UART Host application.

The Wireless UART Host application is a demonstration of the Extended NBU architectural concept, where the Bluetooth LE Host Stack and the Link Layer both run on the NBU core, while the user-facing application runs on the Application core. The communication between the application and the Host is done via the FSCI protocol running on the inter-core RPMSG transport.

The Wireless UART Host application must be flashed together with the NCP FSCI Blackbox application.

Implemented profile and services The Wireless UART Host application implements both the GATT client and server for the custom Wireless UART profile and services.

- Wireless UART Service (UUID: 01ff0100-ba5e-f4ee-5ca1-eb1e5e4b1ce0)
- Battery Service v1.0
- Device Information Service v1.1

The Wireless UART service is a custom service that implements a custom writable ASCII Char characteristic (UUID: 01ff0101-ba5e-f4ee-5ca1-eb1e5e4b1ce0) that holds the character written by the peer device.

The application behaves at first as a GAP central node. It enters GAP Limited Discovery Procedure and searches for other Wireless UART devices to connect. To change the device role to GAP peripheral, use the **ROLESW** button. The device enters GAP General Discoverable Mode and waits for a GAP central node to connect.

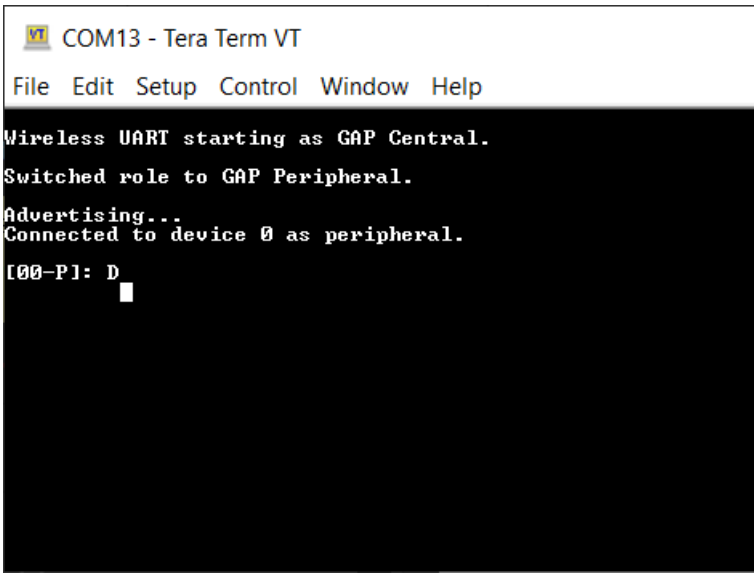
Parent topic: Wireless UART Host

Supported platforms The following platforms support the Wireless UART Host application:

- MCX-W72-EVK
- FRDM-MCXW72

Parent topic: Wireless UART Host

User interface Ensure that both NCP FSCI Blackbox (for the NBU core) and Wireless UART Host (for the Application core) have been flashed to the board.



After flashing the board, the device is in idle mode (all LEDs flashing). To start scanning, press the **SCANSW** button. When in GAP Limited Discovery Procedure of GAP General Discoverable Mode, **CONNLED** is flashing. When the node connects to a peer device, **CONNLED** turns solid. To disconnect the node, hold the **SCANSW** button pressed for 2-3 seconds. The node then re-enters GAP Limited Discovery Procedure.

Parent topic: Wireless UART Host

Usage The application is built to work with another supported platform running either Wireless UART or Wireless UART Host, or with the Wireless UART from the IoT Toolbox application.

When testing with two boards, perform the following steps:

1. Open a serial port terminal and connect to the two boards, in the same manner described in Testing devices. The start screen is blank after the board is reset.
2. The application starts as a GAP central. To switch the role to a GAP peripheral, press the role switch. Depending on the role, when pressing the **SCANSW**, the application starts either scanning or advertising.
3. As soon as the **CONNLED** turns solid on both devices, the user can start writing in one of the consoles. The text appears on the other terminal.
4. After creating a connection, the role (central or peripheral) is displayed on the console. The role switch can be pressed again before creating a new connection. See the figure below.

Tera Term – received text on Wireless UART

When testing with a single board and the IoT Toolbox, perform the following steps:

1. Open a serial port terminal and connect the board in the same manner described in Testing devices. The start screen is blank after the board is reset.
2. Press the role switch button to behave as a GAP peripheral and then press the **SCANSW** button to start advertising. The IoT Toolbox app can then connect. Select UART instead of Console and start typing, as shown in the Figure.

Parent topic: Wireless UART Host

Parent topic:*Bluetooth LE stack and demo applications*

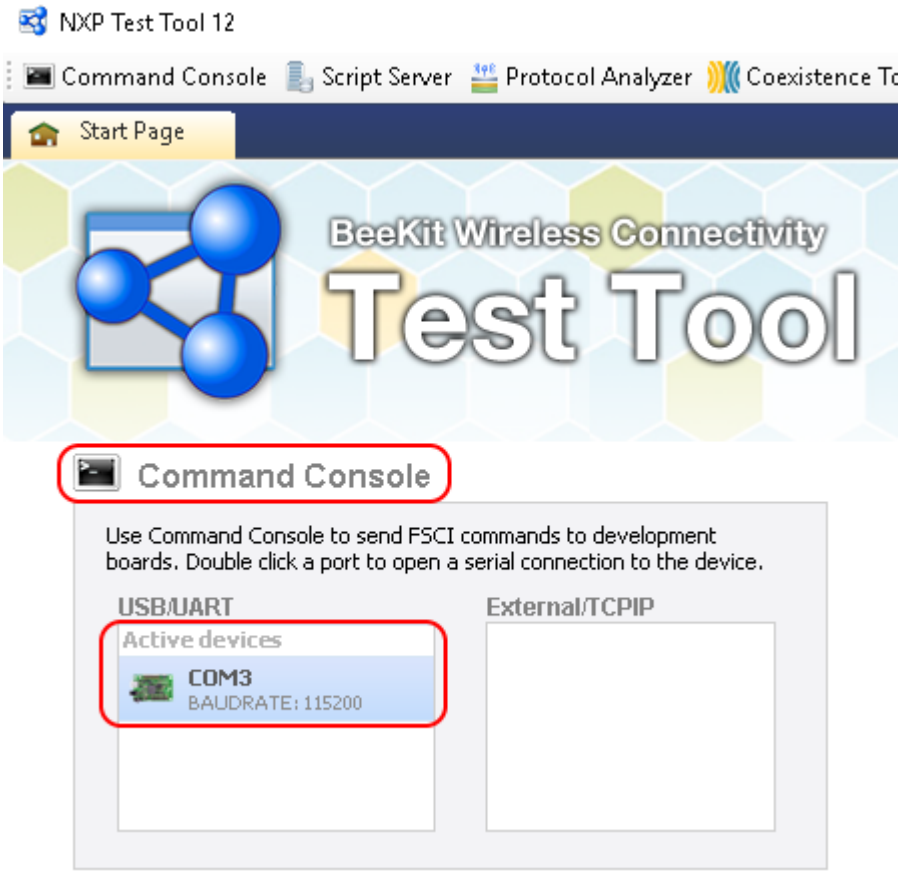
FSCI Bridge This section describes the functionality, user interactions, and testing methods for the FSCI Bridge demo application.

Description The FSCI Bridge demo application is a demonstration of the Extended NBU architectural concept, where the Bluetooth LE Host Stack and the Link Layer both run on the NBU core, while the user-facing application runs on the Application core. The communication between the application and the Host is done via the FSCI protocol running on the inter-core RPMSG transport

The FSCI Bridge runs on the Application core and it is a simple application whose purpose is to pass FSCI commands received over the serial interface to the NCP FSCI Black Box running on the NBU core. Effectively, the functionality is identical to the regular Bluetooth FSCI Black Box application.

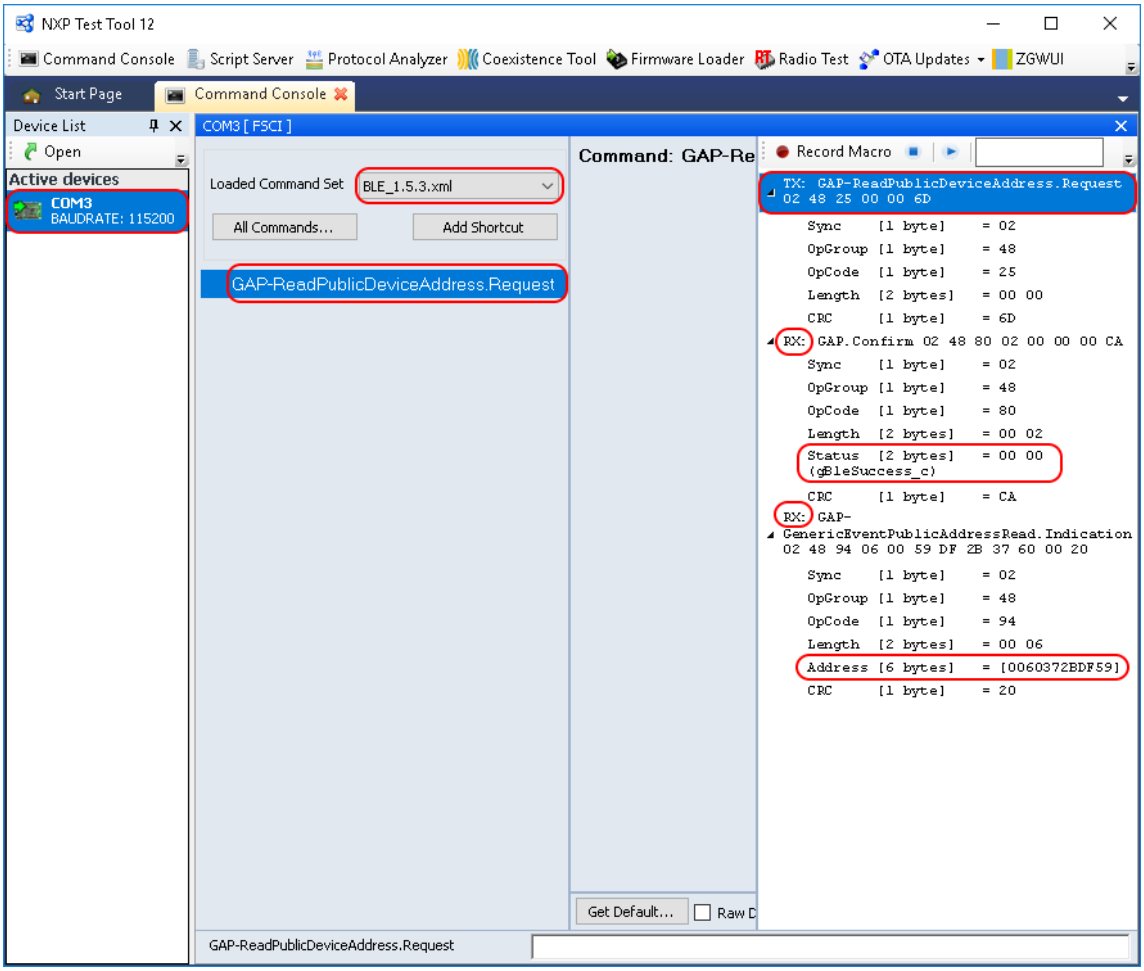
The demo can be used with the Test Tool for Connectivity Products - Command Console application which can be downloaded from the NXP website or using a custom application that supports the FSCI protocol and commands.

Parent topic:FSCI Bridge



Supported platforms The following platforms support the FSCI Bridge application:

- MCX-W72-EVK
- FRDM-MCXW72



Parent topic:FSCI Bridge

Usage with Test Tool for connectivity products The FSCI Bridge demo application is designed to be used via serial interface. This can be done using the TEST Tool for Connectivity Products – Command Console application as described below.

1. Download the FSCI Bridge application onto a supported board's Application core, together with the NCP FSCI Black Box application on the NBU core.
2. Connect the board to a USB port of the PC. The USB COM port drivers must be installed properly and a COM port corresponding to the board should be available.
3. Open the Test Tool application and connect to the serial port corresponding to the board on which the FSCI Bridge application runs. See Figure. The serial communication parameters are: baud rate 115200, 8N1, and no flow control.

4. Select the appropriate Test Tool XML file from the drop-down list for the release being used and send commands to the application. An example is shown in Figure.

Parent topic:FSCI Bridge

Parent topic:*Bluetooth LE stack and demo applications*

NCP FSCI Black Box This section describes the functionality of the NCP FSCI Black Box demo application.

Description The NCP FSCI Black Box application is a demonstration of the Extended NBU architectural concept, where the Bluetooth LE Host Stack and the Link Layer both run on the NBU core, while the user-facing application runs on the Application core. The communication between the application and the Host is done via the FSCI protocol running on the inter-core RPMSG transport.

The NCP FSCI Black Box application runs on the NBU core and provides access to the Bluetooth LE Host Stack through FSCI to the application running on the Application core. It can be paired with the FSCI Bridge application to obtain a functionality that is identical to the regular Bluetooth FSCI Black Box application, or with the Wireless UART Host application to obtain a functionality that is identical to the regular Wireless UART application.

Parent topic:NCP FSCI Black Box

Supported platforms The following platforms support the NCP FSCI Black Box application:

- MCX-W72-EVK
- FRDM-MCXW72

Bluetooth Low Energy CCC Digital Key R3 Application Note

Introduction NXP provides hardware platforms to implement Bluetooth Low Energy applications implementing the Car Connectivity Consortium (CCC) Digital Key R3 functionality. This document provides an overview of the deployment and operation of such applications. This document is also a user guide for the sample applications included in the SDK release package.

Audience This document is for firmware and system developers who create CCC Digital Key-enabled products. The document also provides a high-level description of CCC Digital Key application scenarios that can be deployed on NXP development boards.

Parent topic:*Introduction*

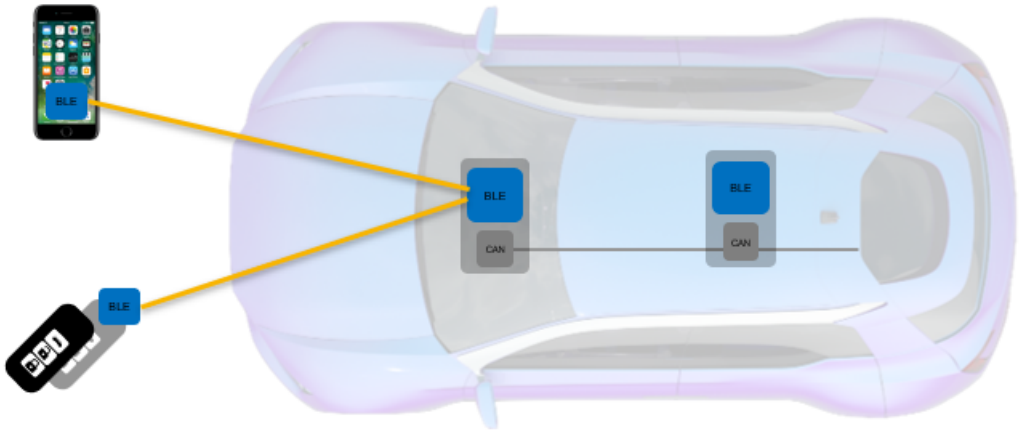
CCC Digital Key technology overview The Car Connectivity Consortium (CCC) is a cross-industry organization advancing global technologies for smartphone-to-car connectivity solutions. CCC has developed Digital Key, a new open standard to allow smart devices such as smartphones to act as a vehicle key. Digital Key lets drivers lock and unlock their cars and even allows them to start the engine and share access to friends or valets, using their phones.

The Digital Key Release 3.0 specification enhances Digital Key Release 2.0 by adding passive, location-aware keyless access. Rather than having to pull their mobile devices out to access a car, consumers are able to leave their mobile device in their bag or pocket when accessing and/or starting their vehicle. Passive access is not only vastly more convenient and a better overall user experience, it also allows vehicles to offer new location-aware features.

To support these new features, the CCC has developed a specification based on Bluetooth Low Energy in combination with Ultra-Wideband (UWB) to enable passive keyless access and to allow secure and accurate positioning.

CCC Digital Key applications overview **Note:** The applications described below implement only the Bluetooth Low Energy functionality described by CCC Digital Key R3. They do not include any UWB or Secure Element functionality. The establishment of secure communications between the demos is simulated using dummy messages.

Digital Key Car Anchor The Digital Key Car Anchor demo application implements one of the multiple Bluetooth Low Energy anchors that can reside inside the car. The anchor performs a dual role. Inside the CCC Digital Key scope, it is a Bluetooth Low Energy peripheral which, depending on the scenario, can perform both Legacy (1M PHY) and Extended Long Range (500 kbps Coded PHY) advertising, searching for a CCC Digital Key-enabled device such as a smartphone.



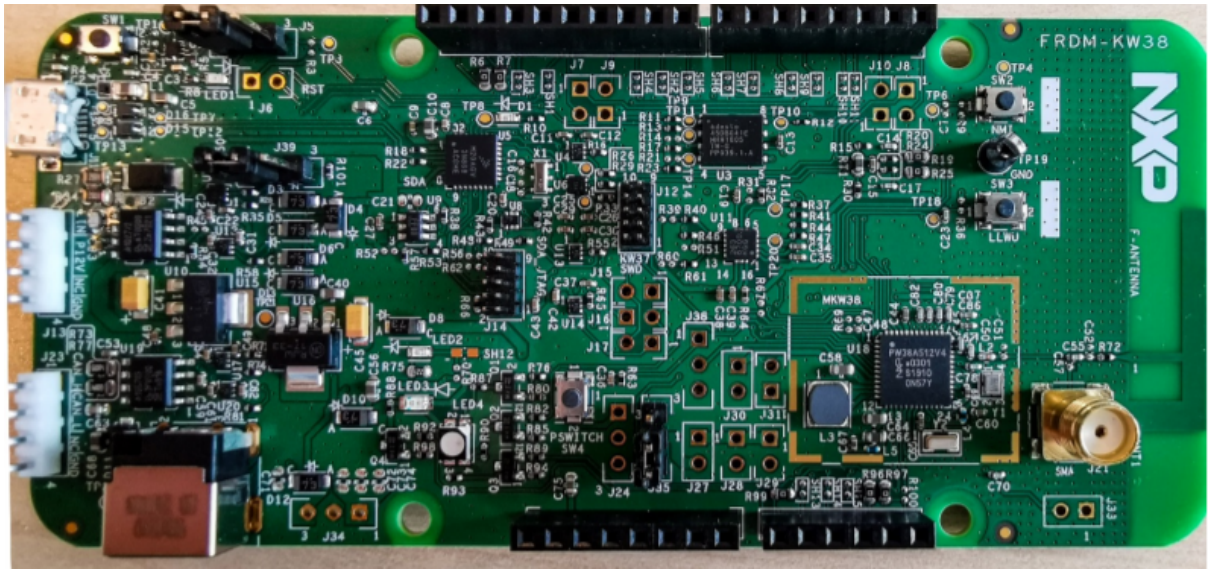
Simultaneously it can also act as a Bluetooth Low Energy central, scanning for non-CCC key fobs. There can be multiple anchors inside a car. The anchors must act as a single device and share information between them (addresses, bonding data, application specific keys, and such data) such that a smartphone can connect to any one of them depending on positioning and not detect any difference.

Parent topic:*CCC Digital Key applications overview*

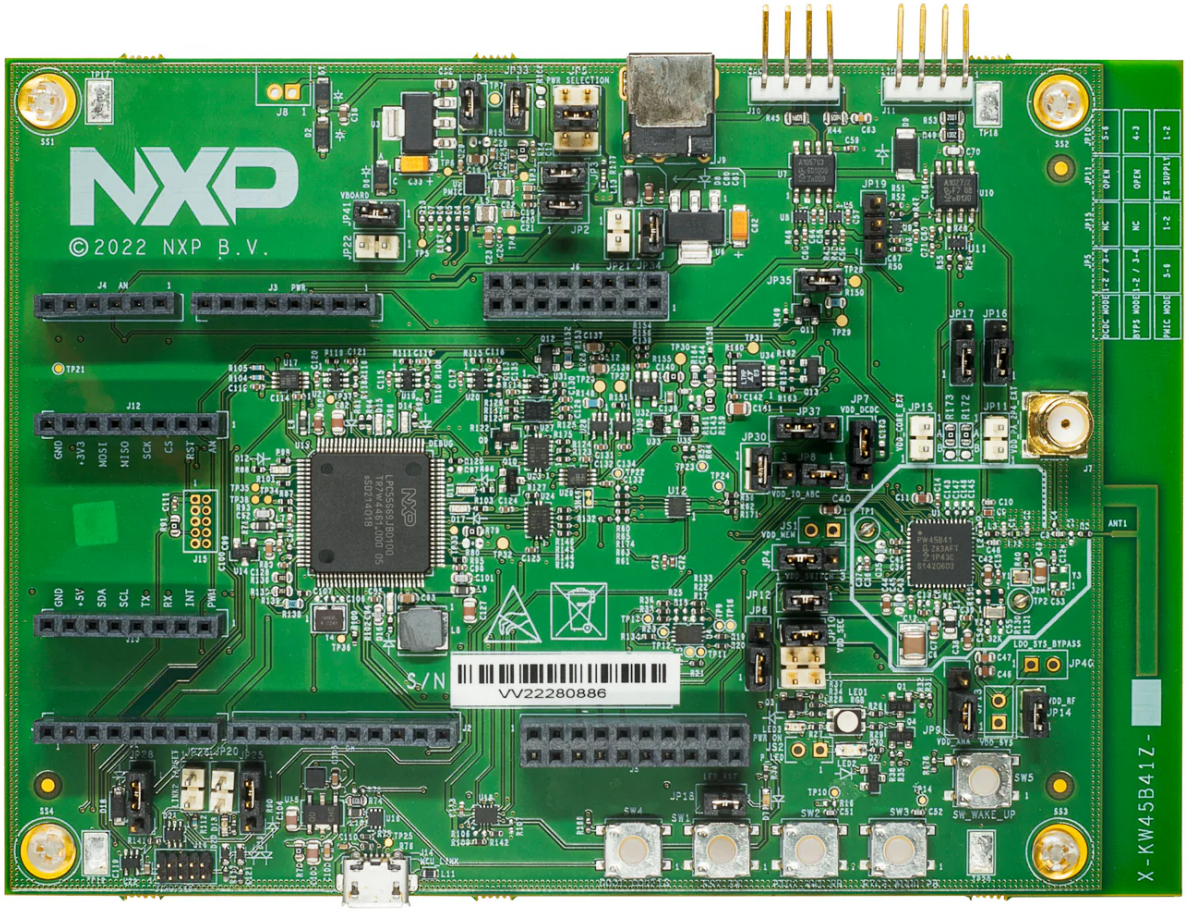
Digital Key Device The Digital Key Device demo application emulates a CCC Digital Key-enabled smartphone. It acts as a Bluetooth Low Energy central device, scanning for advertising coming from a Digital Key Car Anchor.

The Figure 1 shows an example deployment of CCC Digital Key R3. Inside the car, there are two Bluetooth Low Energy anchors connected to each other. The Controller Area Network (CAN) bus connects these anchors and is used to exchange security data and other information. Any anchor can perform both advertising and scanning and it is able to connect to a CCC Digital Key R3-enabled smartphone as well as to a non-CCC key fob.

Anchor communicating with a smartphone (CCC) and a key fob (non-CCC)

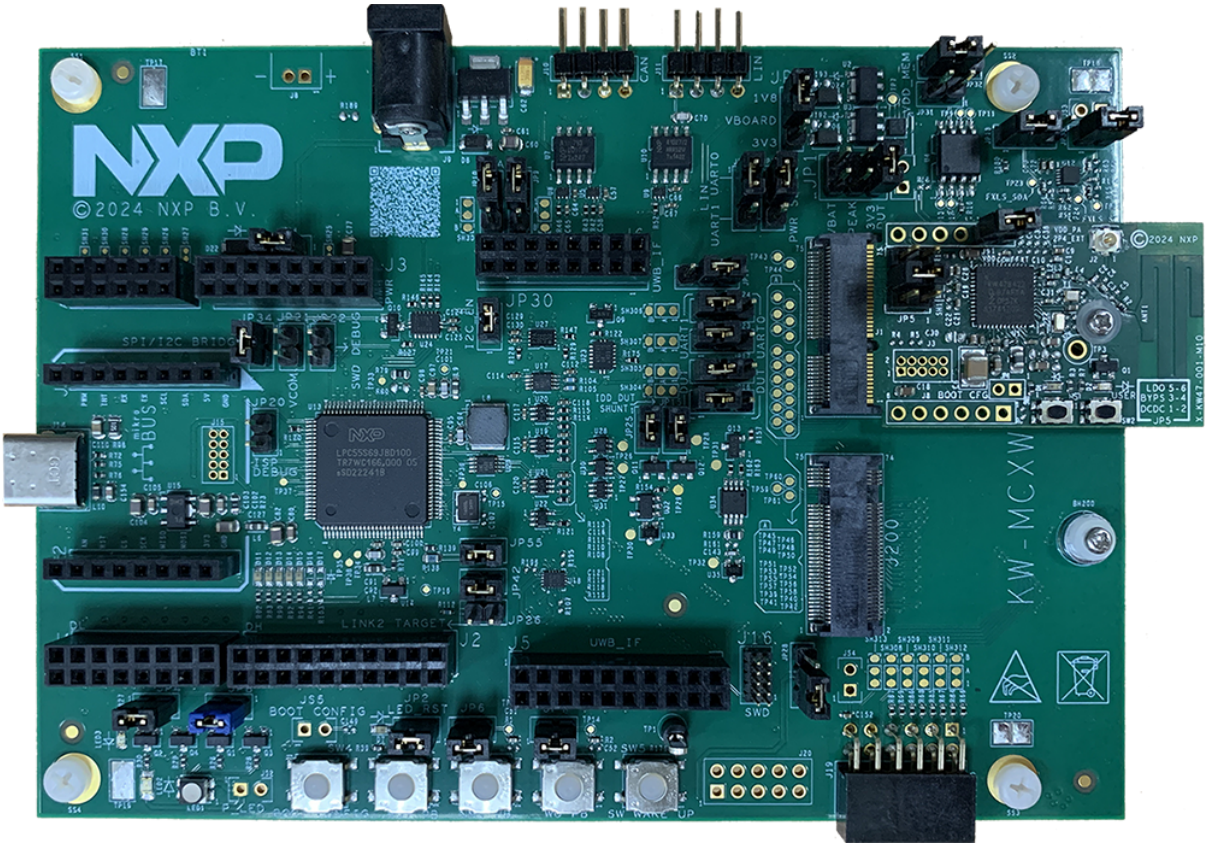


Parent topic:*CCC Digital Key applications overview*

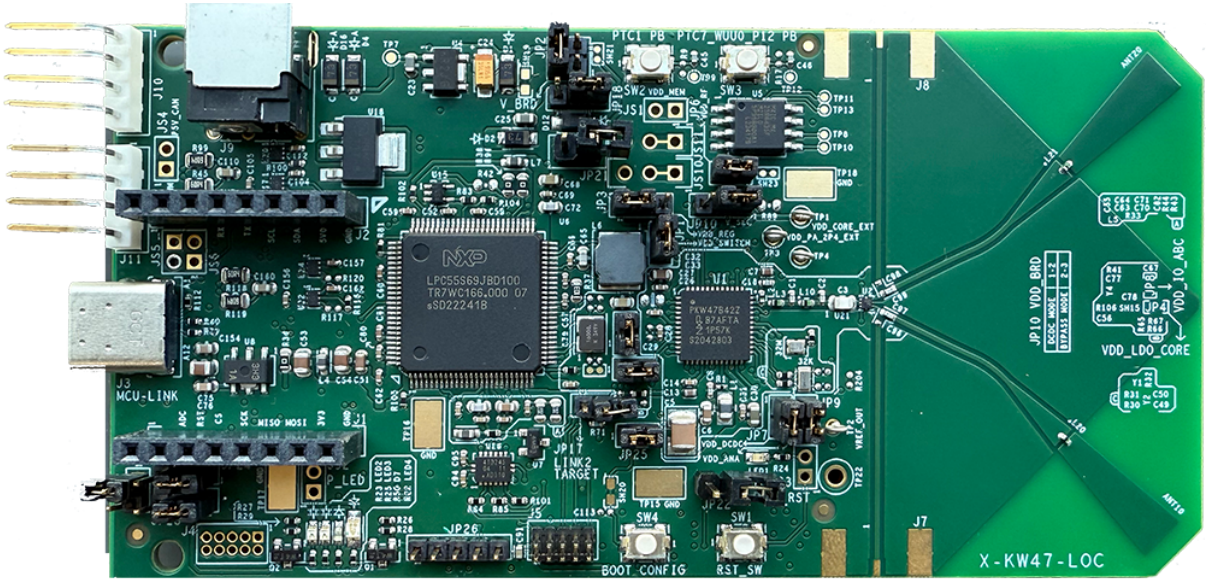


CCC Digital Key hardware platforms The CCC Digital Key R3 demo applications support the following platforms that have Bluetooth Low Energy transceiver capabilities:

- FRDM-KW38 (see Figure 1)
- KW45B41Z-EVK (see Figure 2)
- KW47-EVK (see Figure 3)
- KW47-LOC (see Figure 4)



FRDM-KW38 board



KW45B41Z-EVK board

KW47-EVK board

KW47-LOC board

Deploying CCC Digital Key applications software The software package includes the components necessary for CCC Digital Key R3 application development on the selected NXP platform. These components include:

- Bluetooth Low Energy Host and Controller software libraries (KW38)
- NBU image binaries
- Examples of demo application projects corresponding to CCC Digital Key roles (Device and Car Anchor)

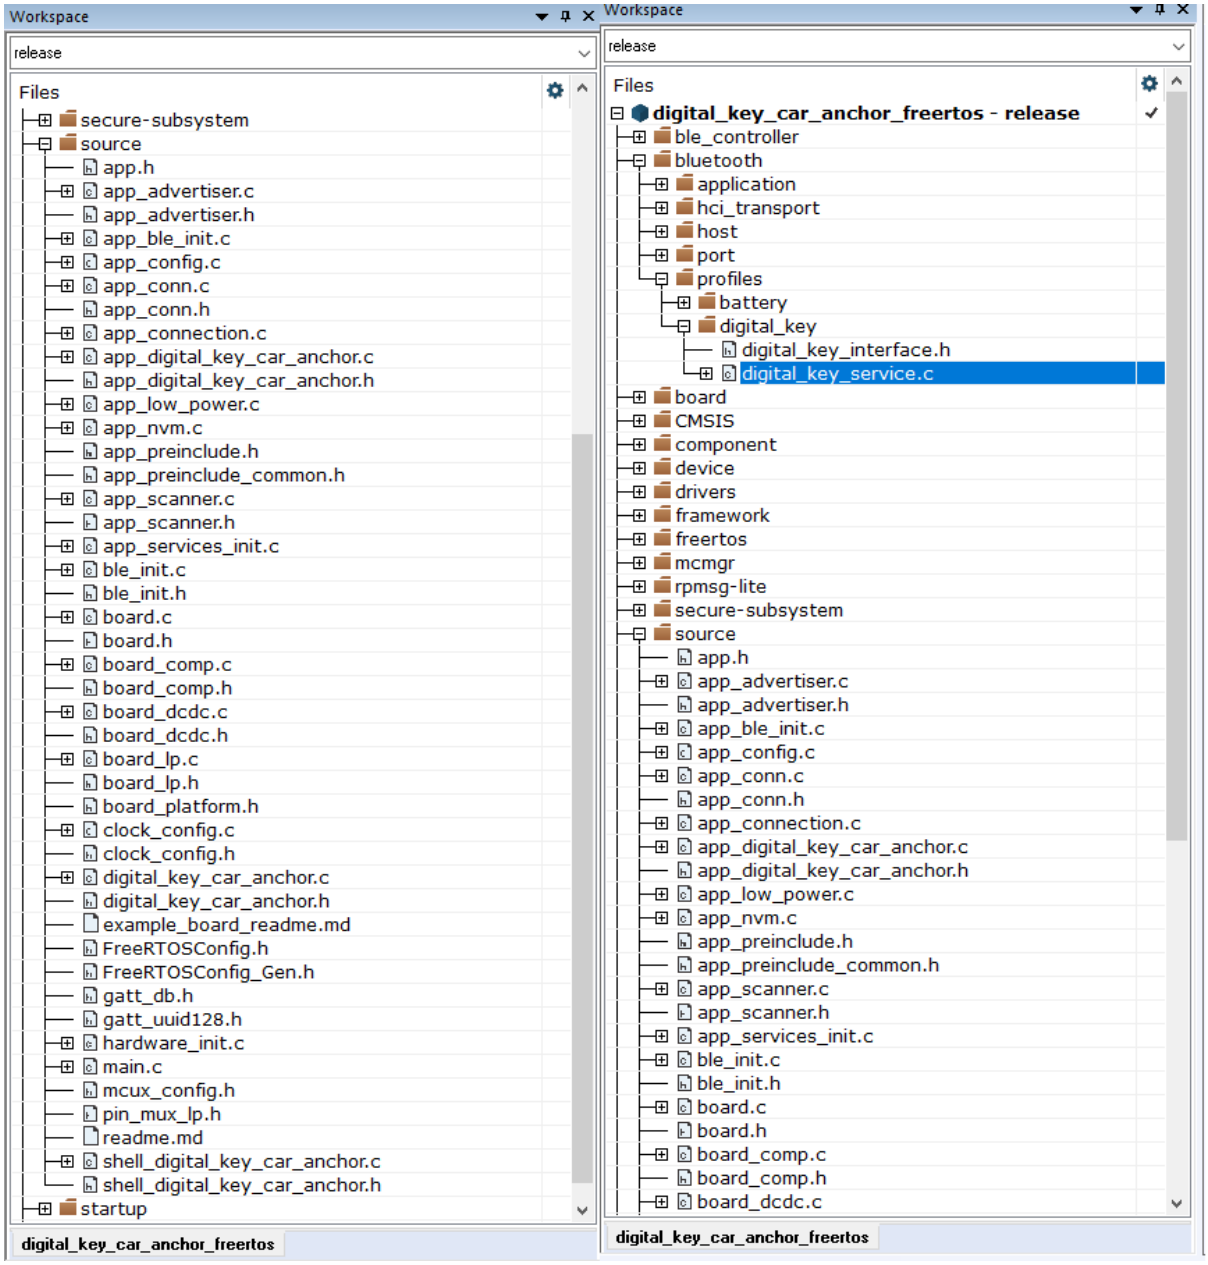
- Platform peripheral drivers, platform startup code, other generic platform software

Note:

Prior to loading any wireless SDK example, update your NBU image with the provided binaries in the following folder of the SDK:

../middleware/wireless/ble_controller/bin.

The demo applications were compiled and tested with **IAR Embedded Workbench** for Arm and **MCUXpresso IDE**. It is recommended to use one of these tools.



To open, build, and run any example application, see the *Bluetooth Low Energy Quick Start Guide* document of the corresponding board. The CCC Digital Key R3 examples are built and run in the same fashion as Bluetooth Low Energy examples.

The Figure 1 shows the application folder structure for the *digital_key_car_anchor* project.

The relevant files for CCC Digital Key R3 are the following:

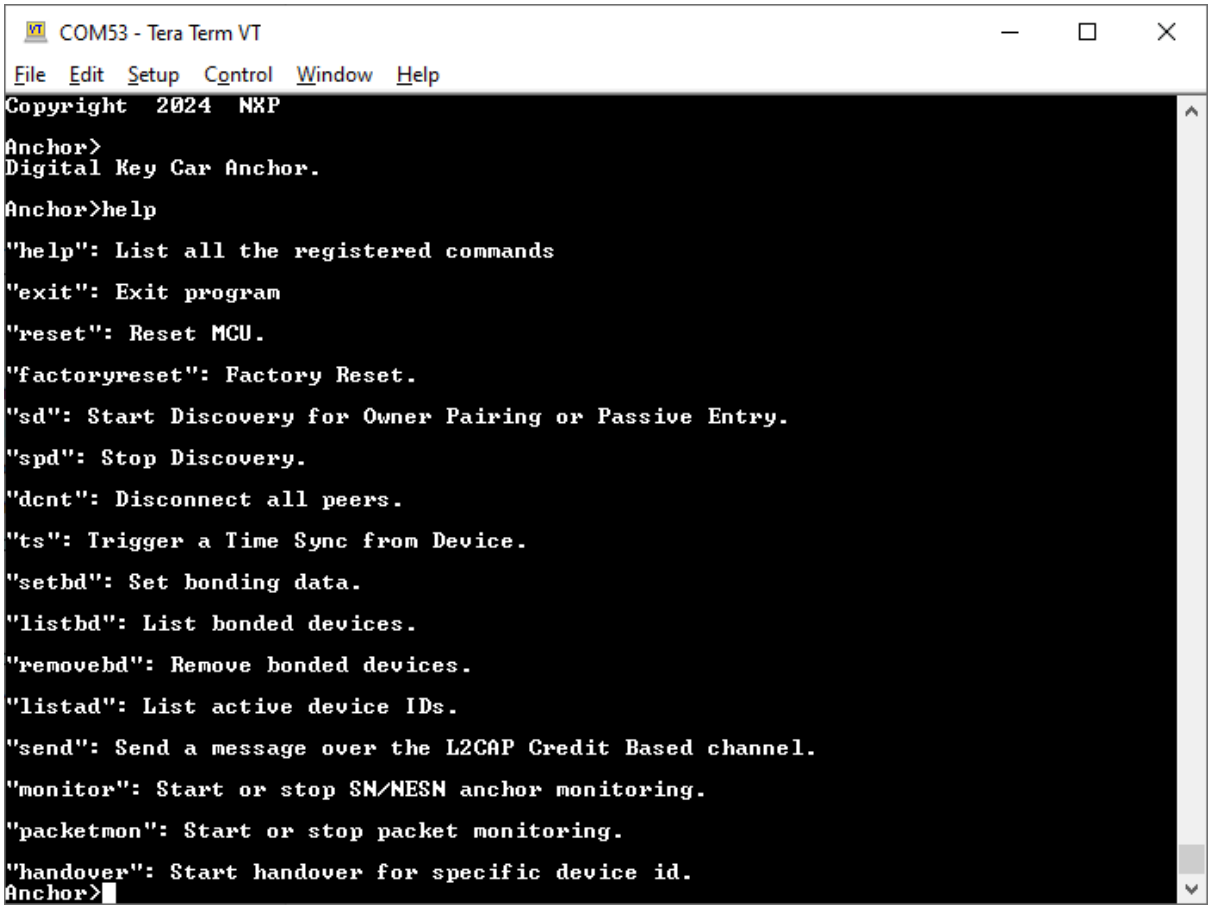
- The main application source files source/digital_key_car_anchor.c and source/app_digital_key_car_anchor.c, and
- The files in bluetooth/profiles/digital_key, which implement the Digital Key Service defined by the CCC Digital Key R3 specification.

Application folder structure in workspace

Demo functionality overview The two demo applications provided showcase the following Digital Key R3 features:

- Owner Pairing between a Device and a Car Anchor
- Passive Entry
- Synchronizing bonding data between Car Anchors
- Connection between a Car Anchor and a non-CCC key fob

The demo applications also showcase the NXP proprietary Connection Handover and Anchor Monitoring features, as well as the A2B feature (secured synchronization of bonding data).

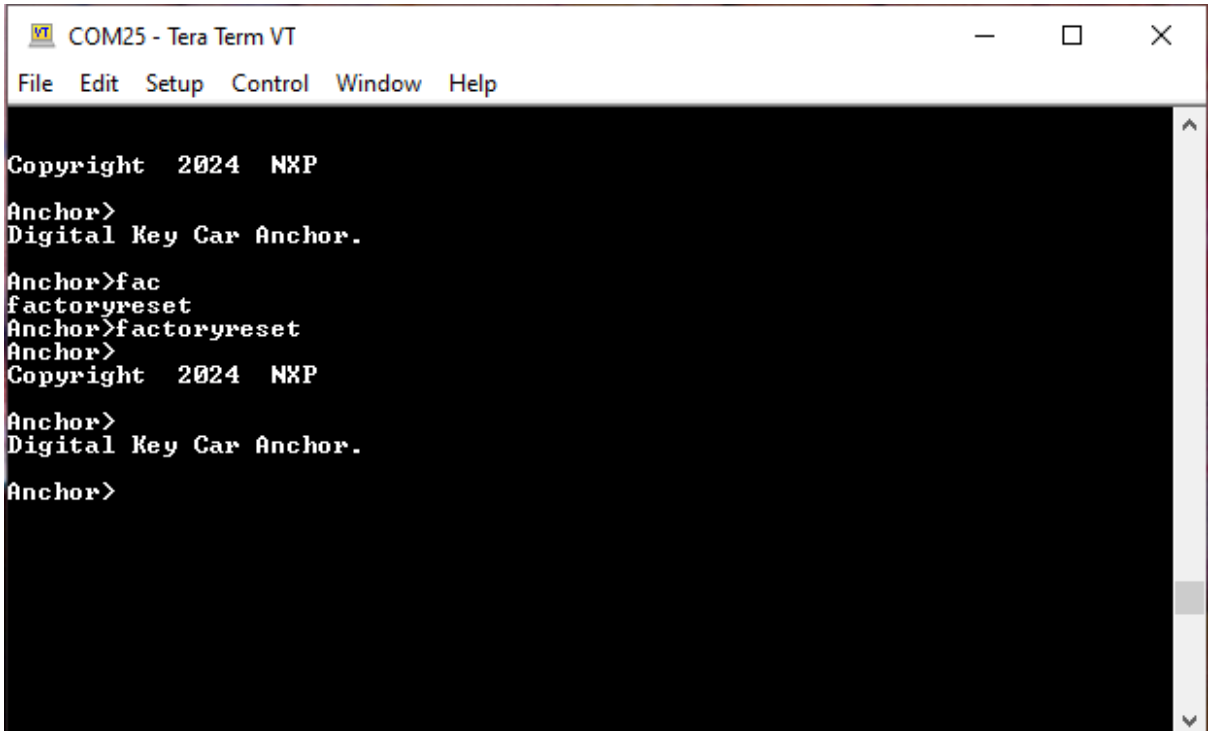


Running CCC Digital Key scenarios using the Shell Interface The following CCC Digital Key R3 examples are provisioned by default with a shell command line interface accessible via a Terminal application such as Tera Term:

- Digital Key Car Anchor

- Digital Key Device

After connecting through the Terminal application and pressing the RST switch on the board, a welcome message appears. Entering the command "help" displays the list of available commands and their descriptions. See Figure 1.



List of commands

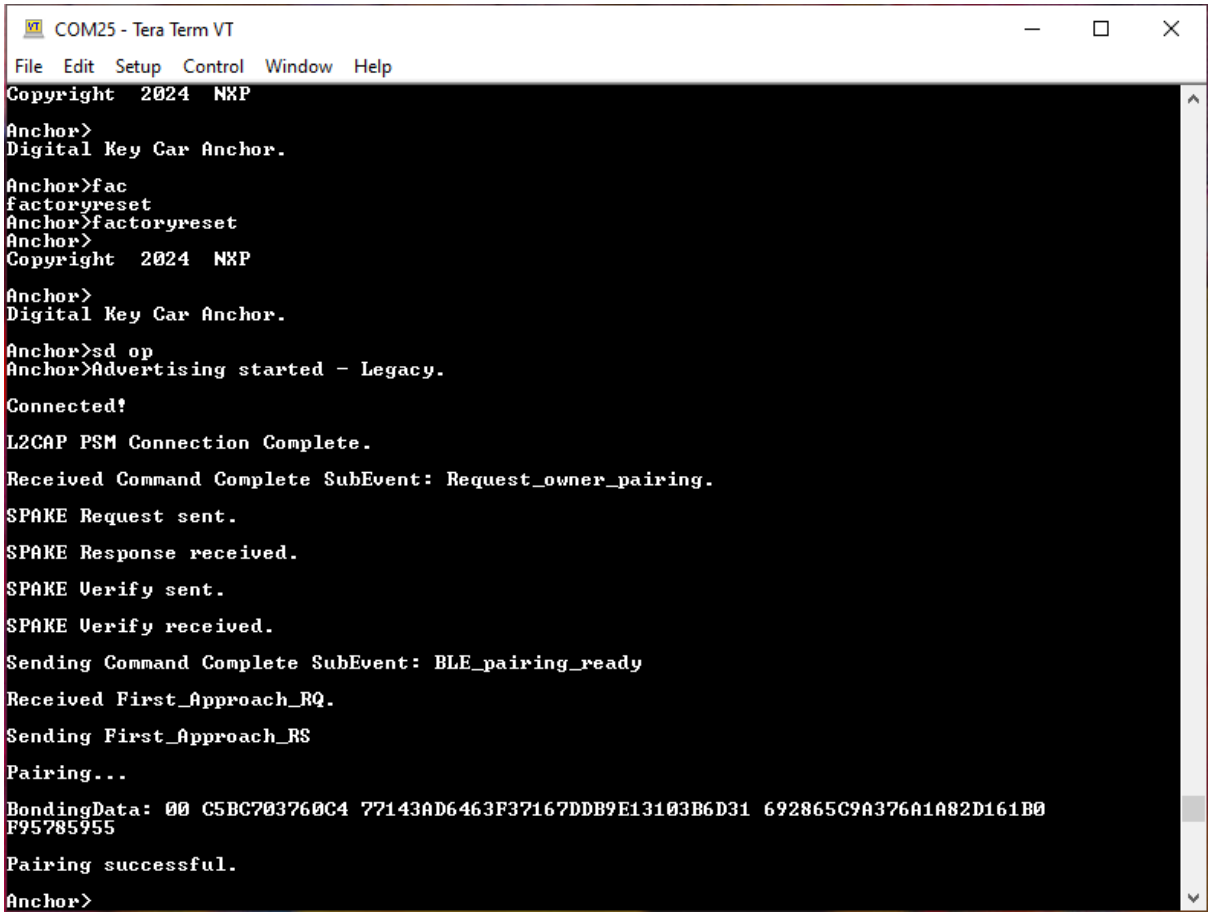
Owner Pairing Scenario Owner Pairing establishes a bond between the Digital Key Car Anchor and the Digital Key Device as per the CCC Digital Key R3 specification. The Car Anchor starts advertising using Legacy mode on the 1M PHY. The Device scans and connects. After establishing the connection, the Device performs service discovery. This step enables it to discover the DK Service and learn the PSM value it would use in order to open an L2CAP channel to the Car Anchor. This channel is used to exchange data and security information as part of the Bluetooth Low Energy Out-of-Band (OOB) pairing process. All security information exchanged consists of dummy messages. The applications do not currently implement any of the UWB and Secure Element functionality described by CCC Digital Key R3.

The first step is to run the "factoryreset" command on both boards in order to ensure no previous bonding data is present in non-volatile memory. See Figure 1.

Factory reset on Car Anchor

The next step is to run the "sd" command (Start Discovery) on the Device and the "sd op" command on the Car Anchor (Owner Pairing advertising differs from Passive Entry, using a single Legacy advertising set on the 1M PHY). The Car Anchor starts advertising while the Device scans. Since both boards have been factory reset, they follow the Owner Pairing flow. The output of the commands is shown in Figure 2.

Owner Pairing on Car Anchor



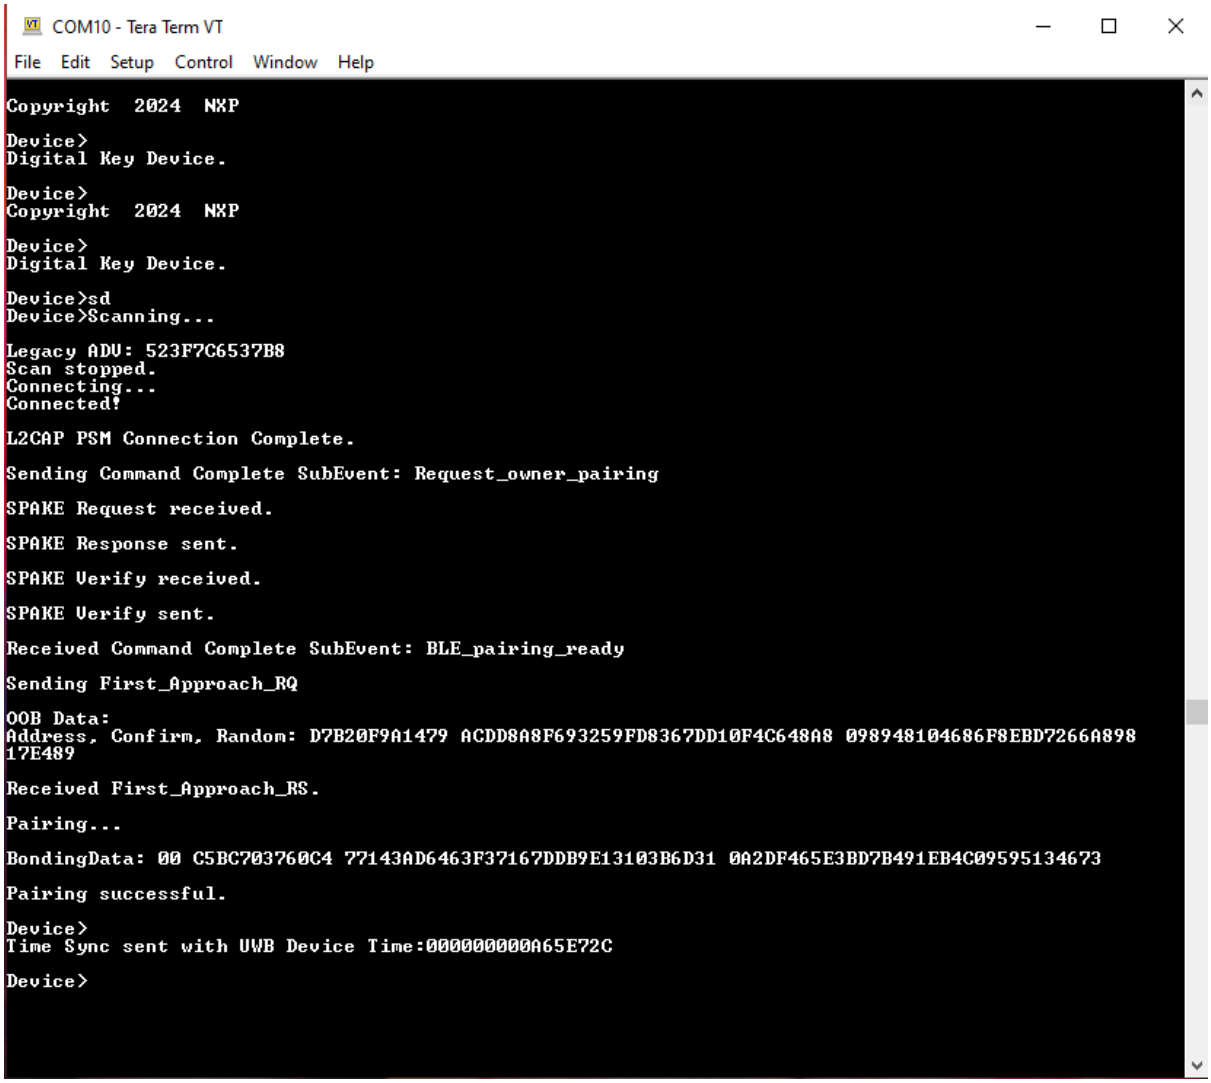


Figure 3 shows the owner pairing on the Device.

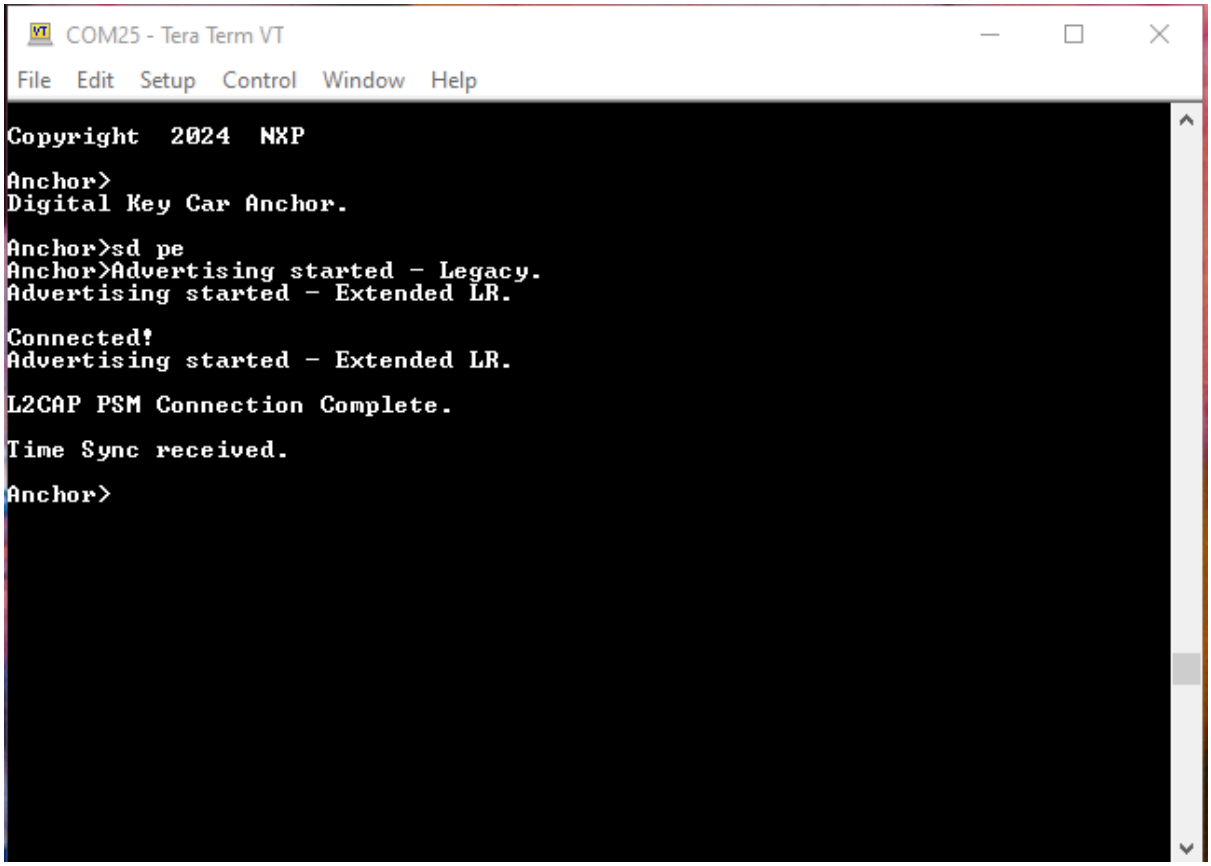
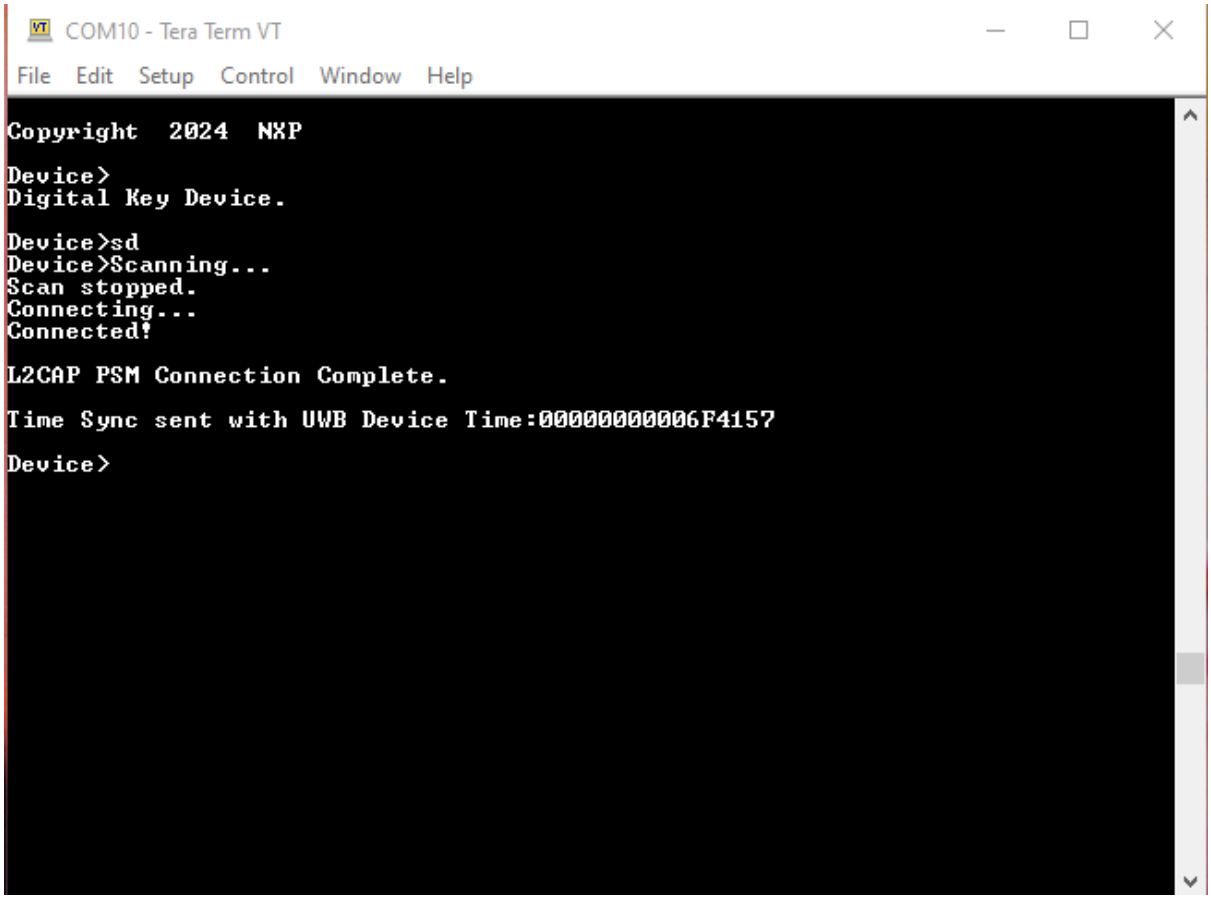
Owner Pairing on Device

Parent topic:*Running CCC Digital Key scenarios using the Shell Interface*



Passive Entry Scenario The Passive Entry scenario runs after Owner Pairing between a Car Anchor and a Device completes successfully.

To run the Passive Entry demo, first, reset the recently paired boards using either the **RST** switch or the "reset" command in the shell. Do NOT perform a factory reset, as this removes the bonding information from non-volatile memory.



After reset, run the "sd pe" command on the Car Anchor and "sd" command on the Device as shown in Figure 1 and Figure 2. For the Passive Entry scenario, the Car Anchor advertises using two sets, one Legacy on the 1M PHY and one Extended on the Coded PHY. If bonding data is present, it follows the Passive Entry flow and stops after the successful creation of the L2CAP channel. At this point the application is functional. The output of the command is shown in Figure 1 and Figure 2. Similar to the Owner Pairing scenario, the applications implement only the Bluetooth Low Energy functionality.

Note: The CCC specification requires using coding scheme S=2 for Coded PHY advertising, equivalent to a data rate of 500 Kbits per sec. To experiment with other coding schemes, change the advertising parameters in the app_config.c file for the digital_key_car_anchor project.

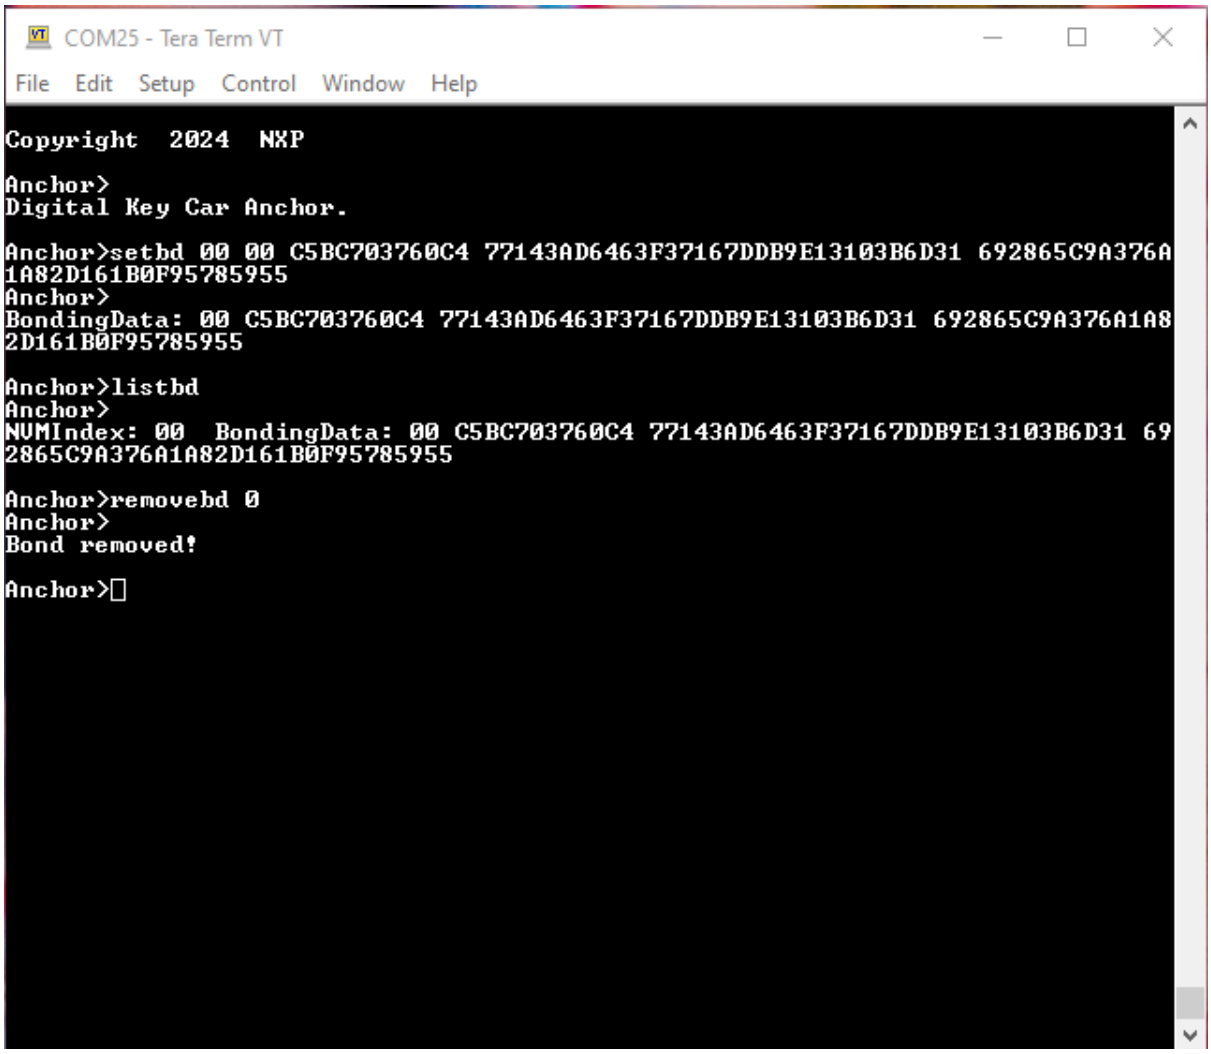
Passive Entry on Car Anchor

Passive Entry on Device

Parent topic:*Running CCC Digital Key scenarios using the Shell Interface*

Synchronizing bonding data between Car Anchors **Note:** On the KW45B41Z-EVK and KW47-EVK platforms, this feature is only valid when Advanced Secure Mode is disabled (gAppSecureMode_d is set to 0 in the app_preinclude.h file). To synchronize bonding data when Advanced Secure Mode is enabled, refer to *Running the A2B scenario*.

Multiple Car Anchors can reside on a car, acting as a single Bluetooth Low Energy device as far as the Device is concerned. When the Device pairs and bonds with a Car Anchor, that bonding data must be shared with all other anchors. To showcase this functionality, the Car Anchor shell demo offers the "setbd" command.



During owner pairing, the bonding data is displayed in the shell as seen in the Owner Pairing section. By passing this data to the "setbd" command on another Car Anchor, that anchor is able to connect with the original Device and perform the Passive Entry flow.

Note: Currently only the Bluetooth Low Energy bonding data is transferred between anchors. No CCC Digital Key R3-specific keys are exchanged.

Saved bonding data can also be viewed using the "listbd" command and a specific bond can be removed using the "removebd" command. See Figure 1 for details.

A bond can only be removed if a connection to that specific device is not currently active. The commands presented in this subsection are also supported on the Device for test purposes.

Adding bonding data to a Car Anchor, listing bonds and removing a bond

Note:

- To simulate anchors residing on the same car, Random Static Address required by the Digital Key protocol and the Identity Resolving Key are set at compile time for the digital_key_car_anchor project. To simulate anchors residing on different cars, change the values of the APP_BD_ADDR and APP_SMP_IRK macros in the project's app_preinclude.h.

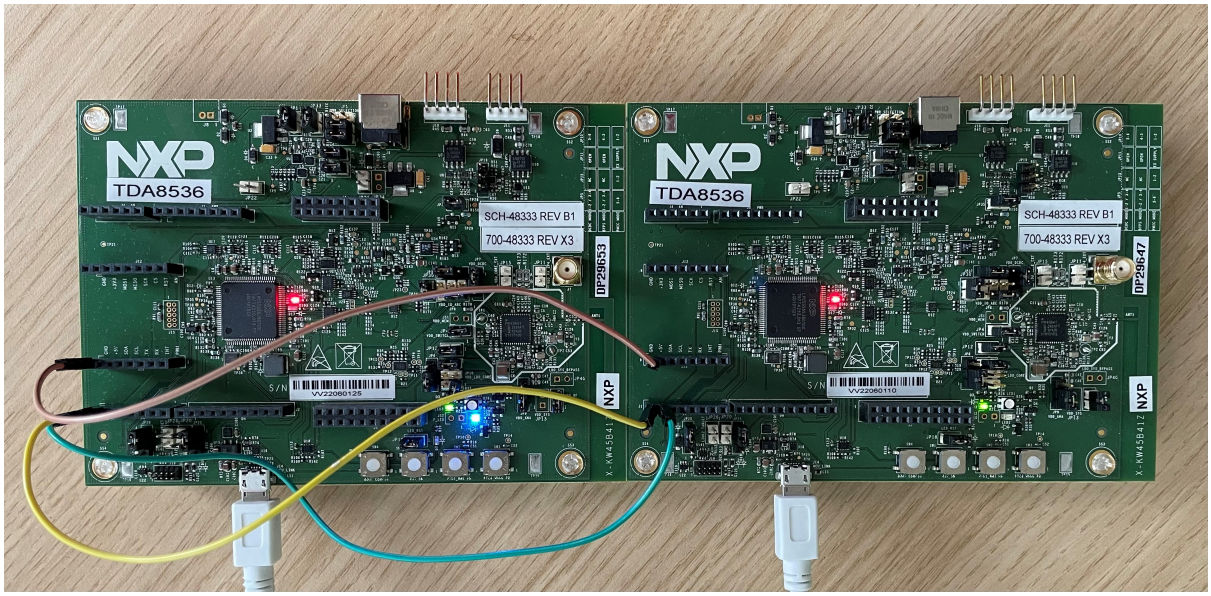
Parent topic:*Running CCC Digital Key scenarios using the Shell Interface*

Connection with a non-CCC Key Fob Scenario The Car Anchor also supports connecting as a Bluetooth Low Energy central device (scanner) to a non-CCC key fob (advertiser). To enable scanning on the digital_key_car_anchor project set the gAppScanNonCCC_d macro to 1 in the project's app_preinclude.h before building.

After flashing the board and running "factoryreset", run the "sd op" or "sd pe" command exactly as in the Owner Pairing or Passive Entry scenarios. The Car Anchor will simultaneously advertise for a CCC Device and scan for a non-CCC key fob.

Connection with the non-CCC key fob and the subsequent application functionality is currently out of this application note's scope.

Parent topic:*Running CCC Digital Key scenarios using the Shell Interface*



Running the Connection Handover scenario Connection Handover is an NXP proprietary feature that enables a Bluetooth Low Energy connection to be seamlessly transferred from one peripheral to another while the central device remains unaware. It is best exemplified by (but not limited to) the CCC Digital Key use case. As a person carrying a phone moves around the vehicle, the Bluetooth Low Energy connection is transferred between Car Anchors in order to ensure the best user experience. From the Device's point of view, it stays in the same initial connection.

The CCC Digital Key demos showcase the Connection Handover feature. The handover is performed on demand via a button press. In a real scenario, the handover is performed based on criteria such as RSSI. The feature is currently supported on the KW45B41Z-EVK and KW47-EVK platforms.

Prerequisites:

- Three boards (two boards act as Car Anchors, one as a Device). The demo is currently limited to a maximum of two Car Anchors.
- The two Car Anchors must have a serial connection via the secondary UART as shown in the image below. The UART connection stands in for a real deployment solution such as a CAN bus.
- The *gHandoverDemo_d* macro must be set to 1 in app_preinclude.h for the ***digital_key_car_anchor*** project. Figure 1 shows KW45B41Z-EVK car anchors connected via secondary UART. *(J1-1 is connected to J1-2 and J1-2 is connected to J1-1. GND connection is J13-1 to J13-1.)*
- If KW47-EVK boards are used, make the UART connection between J1-1 to J1-3 and J1-3 to J1-1.

Two Car Anchors connected via the secondary UART

Demo steps:

- Connect a Car Anchor and a Device using either the Owner Pairing or Passive Entry scenario as detailed in the previous sections. If doing Owner Pairing, the bonding data synchronization between the two Car Anchors will happen automatically over the UART connection.
- Optional: Use the "send" shell command on the Car Anchor to send a test message over the L2CAP Credit-Based channel. The message is displayed in the console on the Device.
- Press the **SW3** switch or use the handover command with the peer device ID on the Car Anchor which is connected to the Device. To see a list of connected devices with their corresponding peer device IDs the listad command may be used.
- The connection is handed over to the second Car Anchor as seen in console messages. LED2 also turns solid blue on the Car Anchor, which has taken over the connection.
- **Optional**: Use the "send" shell command on the Car Anchor that has taken over the connection. The message is displayed in the console on the Device.
- The connection can continue to be handed over back and forth between the two Car Anchors by pressing the **SW3** switch on the Car Anchor which currently has the connection. Figure 2 shows first Car Anchor connects and pairs with the Device, sends the L2CAP test message and successfully performs handover when **SW3** is pressed.

Paring and connection of First Car Anchor with Device and handover

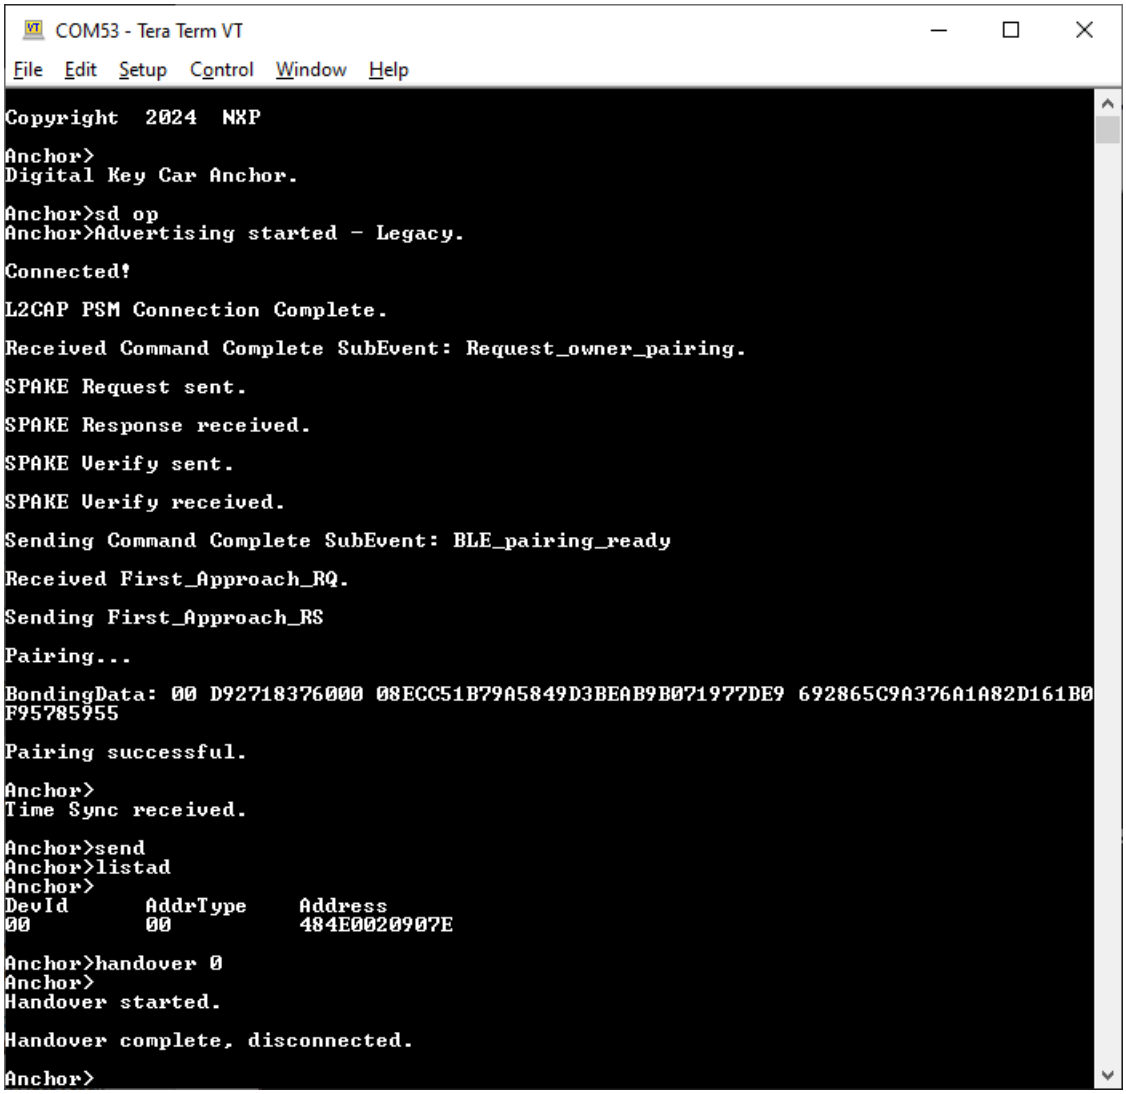


Figure 3 shows that the second Car Anchor receives the bonding data automatically via UART when the first Car Anchor pairs with the Device. After the handover is successfully completed, it sends the L2CAP test message to the Device.

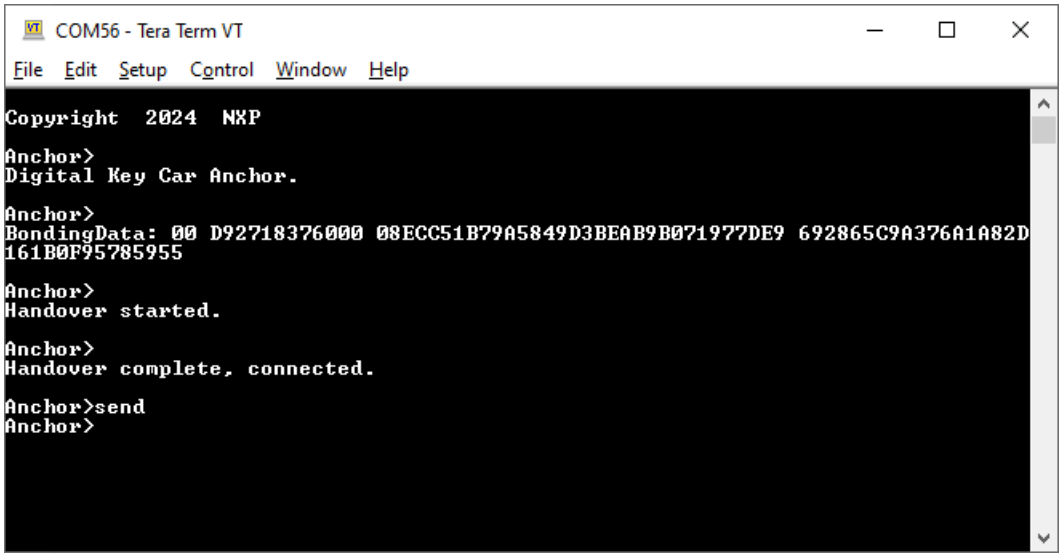
Second Car Anchor receiving the bonding data automatically via UART when the first Car Anchor pairs with the Device



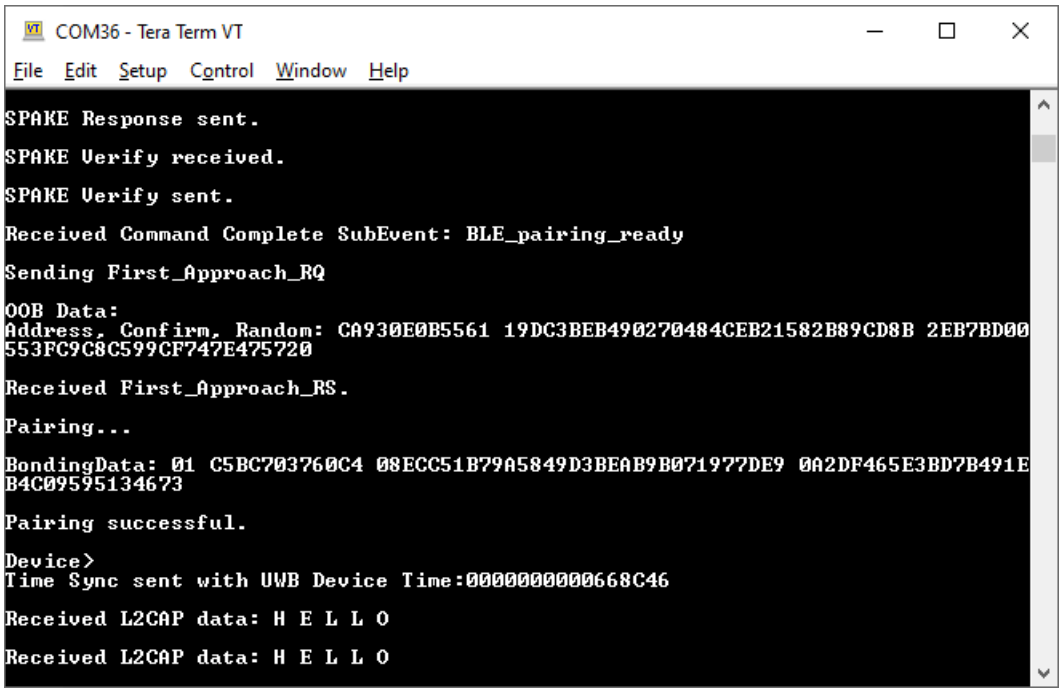


Figure 4 shows the Device receiving both L2CAP test messages. From the device's point of view, it is in a single uninterrupted connection.

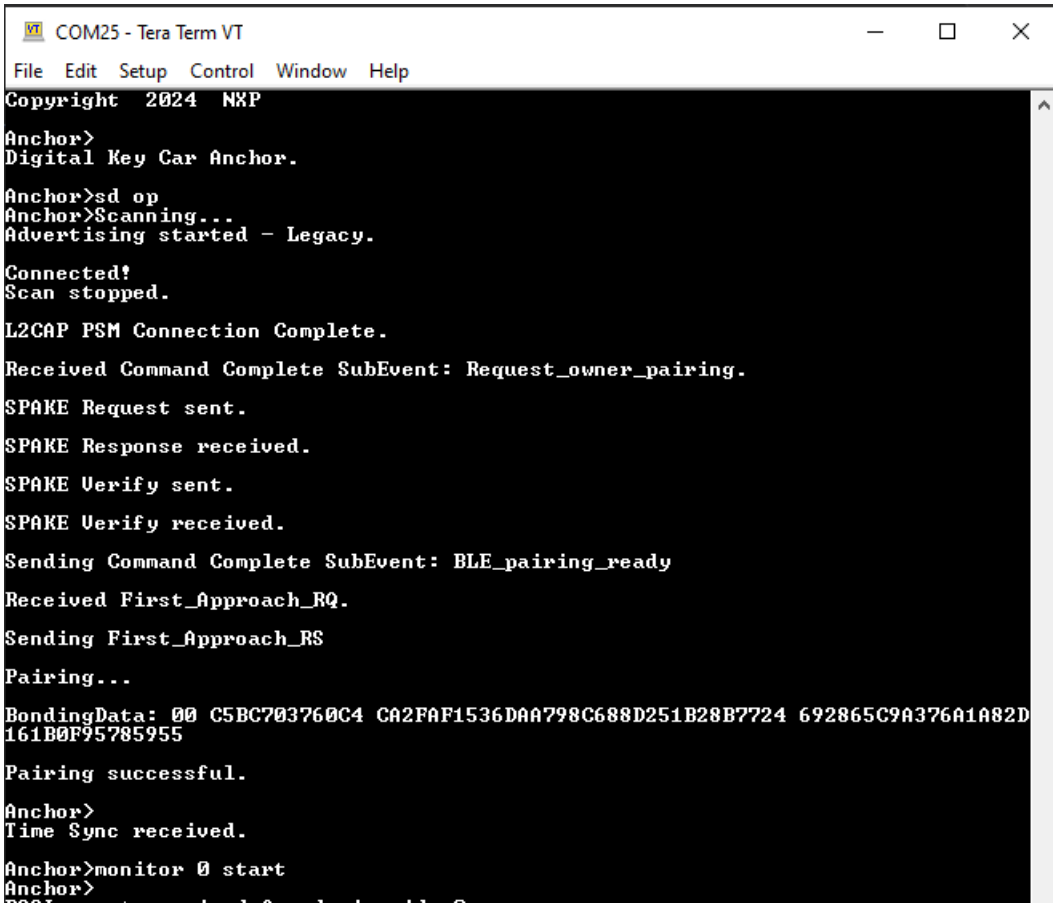
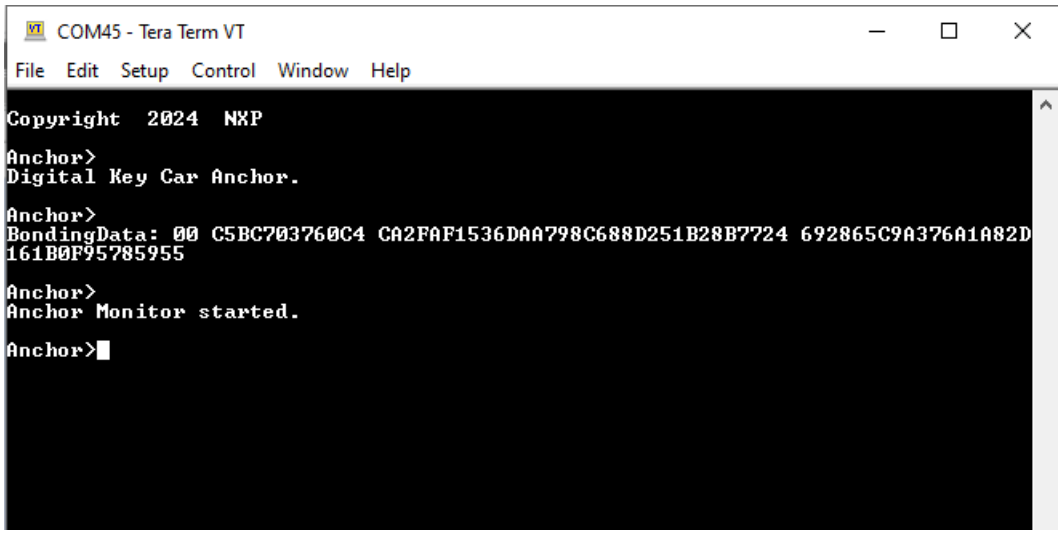
The Device receives both L2CAP test messages



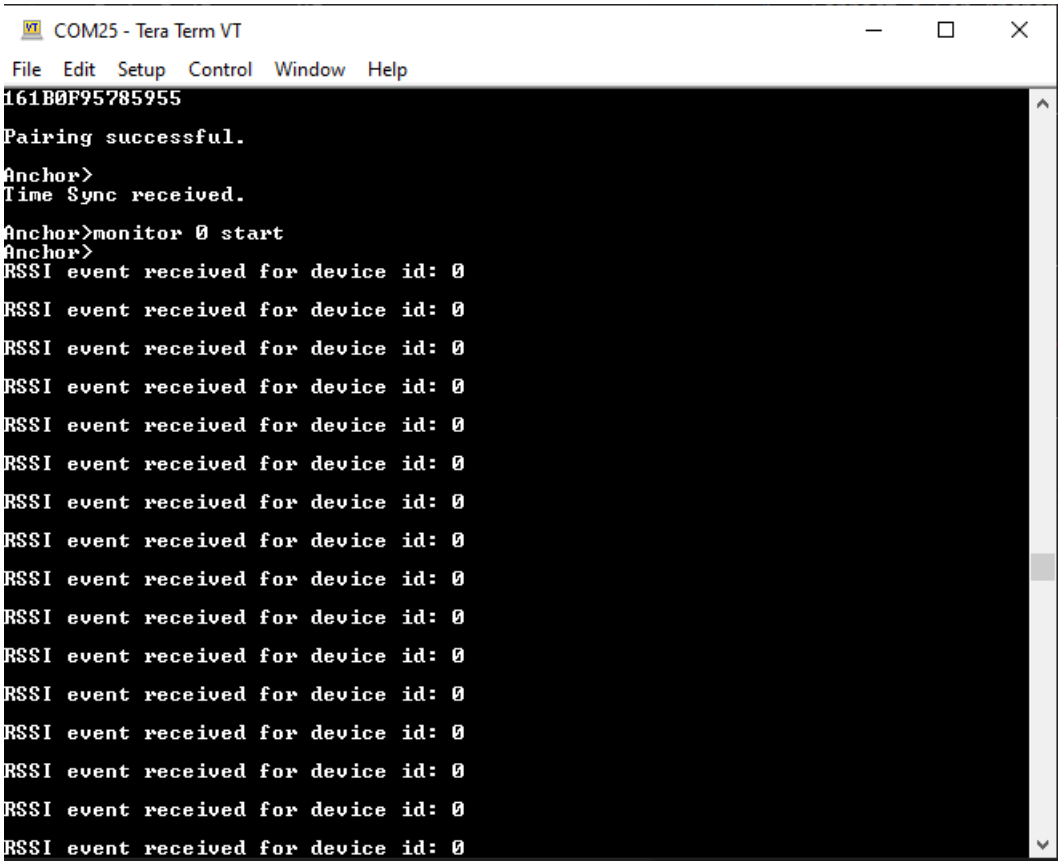
Running the Anchor Monitoring scenario Anchor Monitoring is an NXP proprietary feature that allows a second Anchor to monitor the connection between the first Anchor and the Device. The prerequisites are the same hardware setup as used for the Connection Handover scenario. Note, however, that the Connection Handover scenario cannot be performed while Anchor Monitoring is in progress.

Demo steps:



1. Connect a Car Anchor and a Device using either the Owner Pairing or Passive Entry scenario as described in Owner Pairing Scenario and Passive Entry Scenario.

Anchor has performed Owner Pairing and the "monitor start" command is run



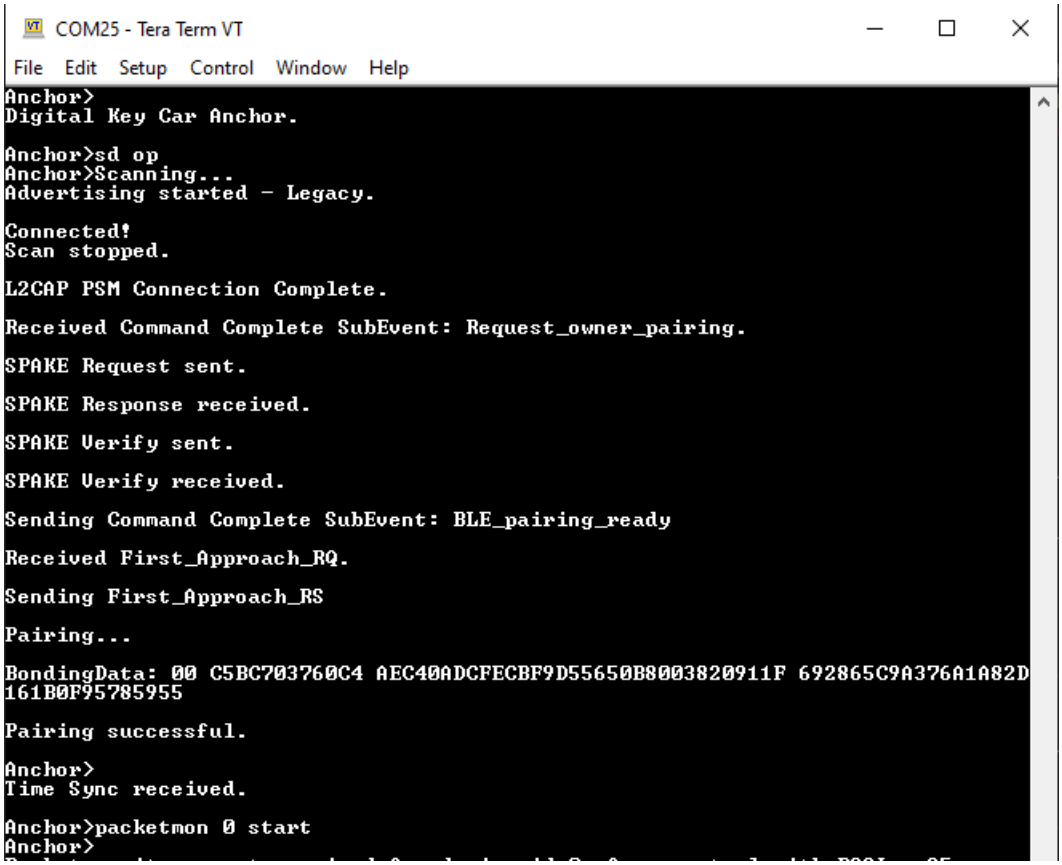
2. Run the "monitor 0 start" shell command on the Car Anchor, as seen in Figure 1.

The second Anchor has received the command over the serial interface and has started Anchor Monitoring

3. The second Car Anchor begins monitoring the connection and receives RSSI info events, which it forwards to the first Car Anchor (see Figure 2).

The first Anchor displays RSSI events received from the second Anchor.

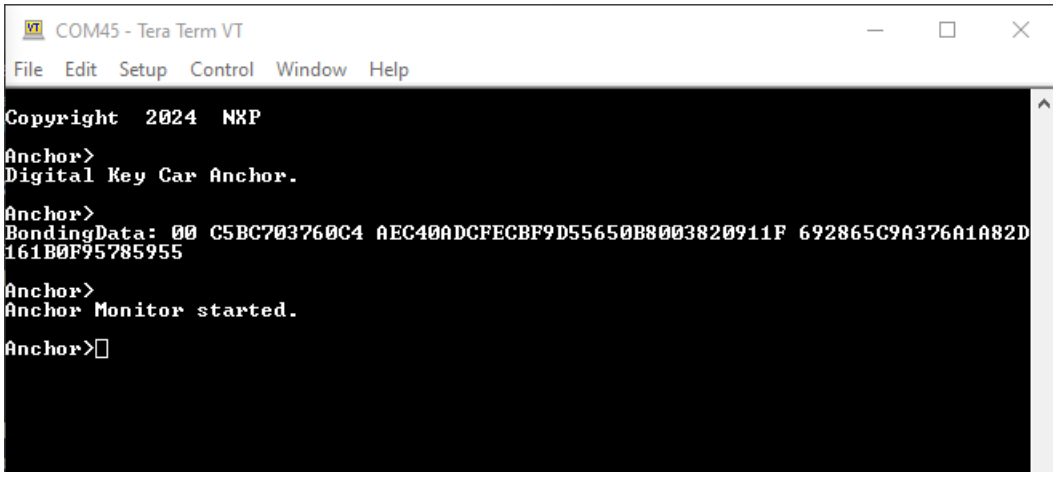
4. The received RSSI messages are displayed in the console (see Figure 3).
5. To stop monitoring, run the "monitor 0 stop" shell command on either Car Anchor (the second one is recommended, as its console is not flooded by RSSI event messages).



Parent topic:*Running the Connection Handover scenario*

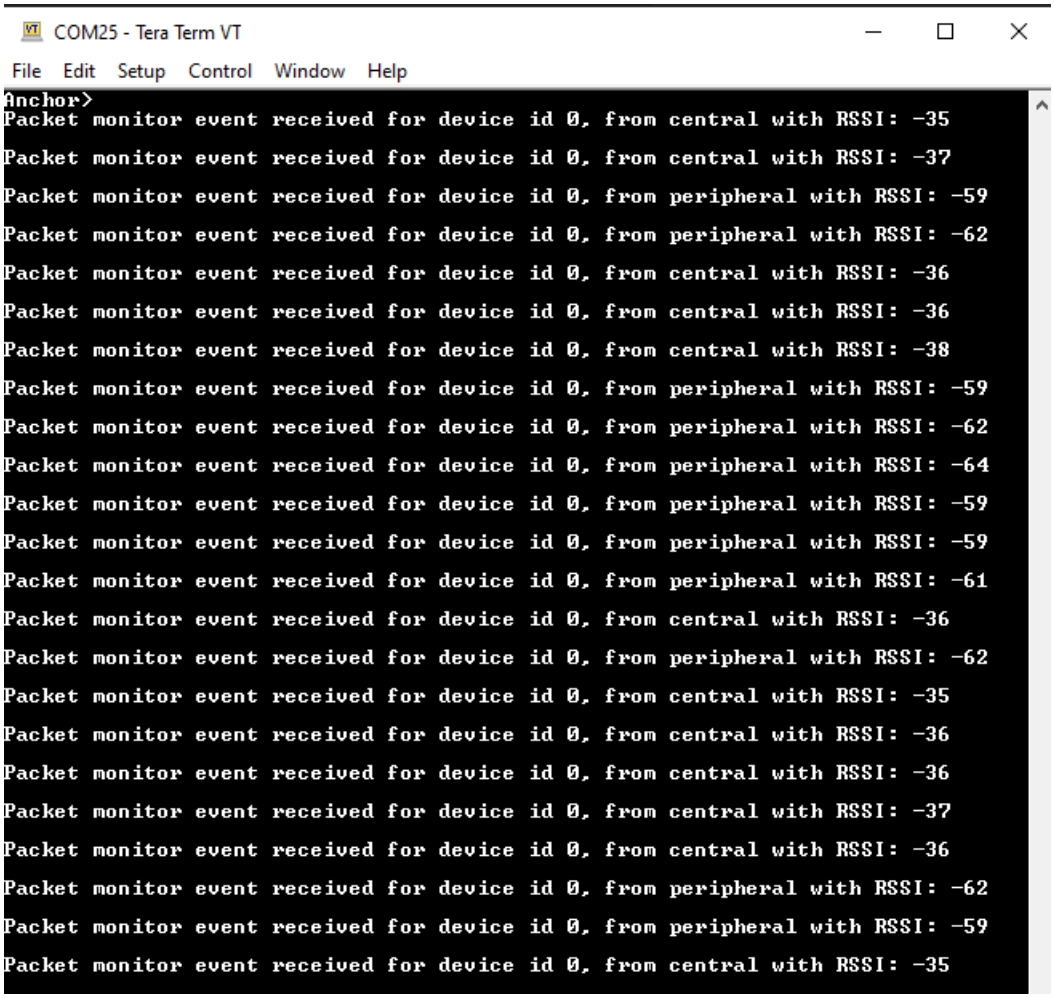
Running the Packet Monitoring scenario Packet Monitoring is an NXP proprietary feature that allows a second Anchor to receive the packets from the connection between the first Anchor and the Device. The prerequisites are the same hardware setup as used for the *Running the Connection Handover scenario*. Note, however, that the Connection Handover scenario cannot be performed while Packet Monitoring is in progress. Packets received by the second Anchor are sent over the serial interface to the first Anchor for processing. The first Anchor determines the source of the packet based on the SN and NESN bits and displays the RSSI.

Demo steps:



1. Connect the first Anchor and a Device using either the Owner Pairing or Passive Entry scenario as described in Owner Pairing Scenario and Passive Entry Scenario.

Anchor has performed Owner Pairing and the "packetmon start" command is run



2. Run “packetmon 0 start” on the first Anchor, as shown in Figure 1.

The second Anchor has received the command over the serial interface and has started Packet Monitoring

3. The second Anchor begins monitoring the connection and receives packet information, which it forwards to the first Anchor. See Figure 2.

The first Anchor displays the RSSI and source device of the received packets from the second Anchor

4. The first Anchor receives the packet information from the second Anchor and determines the source of the packet based on the SN and NESN bits. The source and the RSSI are displayed in the console. See Figure 3.
5. To stop monitoring, run "packetmon 0 stop" shell command on either Anchor (the second one is recommended, as its console is not flooded by packet information messages).

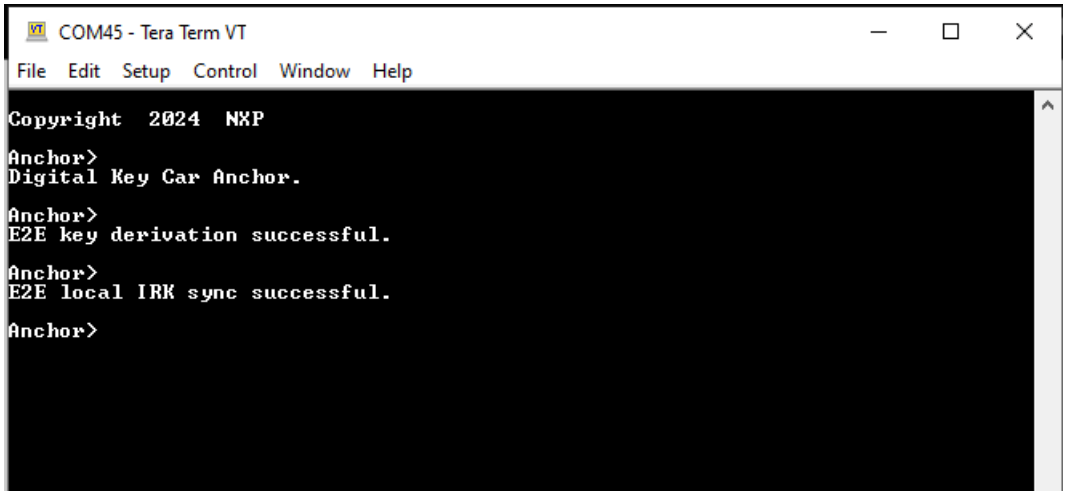
Parent topic:*Running the Connection Handover scenario*

Running the A2B scenario The A2B feature allows for the secure transfer of Bluetooth Low Energy security keys information between the Car Anchor devices. The feature is currently supported on the following platforms:

- KW45B41Z-EVK with a lifecycle state of OEM-Open or higher, this feature is provided by the EdgeLock Secure Enclave.
- KW47-EVK with a lifecycle state of OEM-Open or higher, this feature is provided by th EdgeLock Secure Enclave.

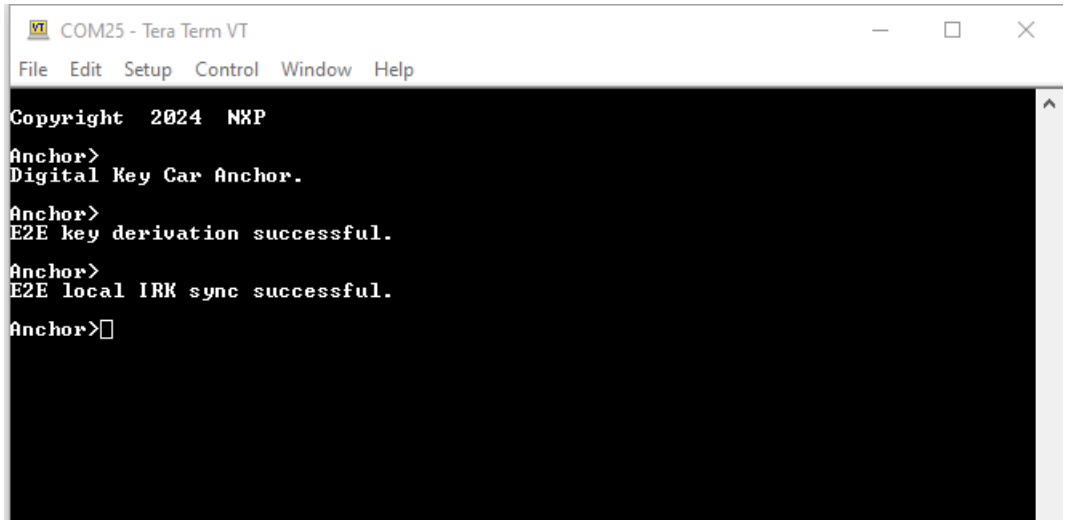
The Car Anchor demo application makes use of the A2B feature to securely synchronize the local IRK and the Bonding Data (LTK and peer IRK) with another Car Anchor.

Prerequisites:



- Three boards (two act as Car Anchors, one as a Device). The demo is currently limited to a maximum of two Car Anchors.
- The two Car Anchors must be connected via a serial interface as described in the section above.

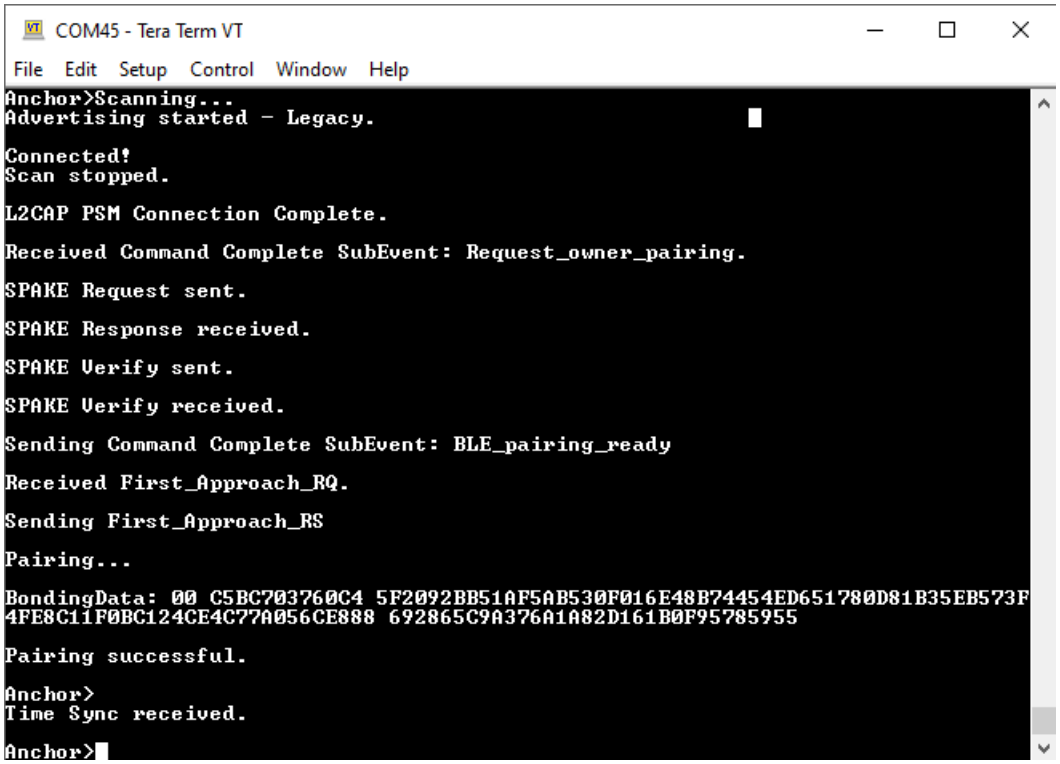
- Advanced Secure Mode must be enabled. The following macros must be defined and set to 1 in app_preinclude.h for the ***digital_key_car_anchor*** project:
  - gAppSecureMode_d
  - gA2BEnabled_d
- One of the Car Anchors must be configured with the gA2BInitiator_d macro set to 1, this is called Car Anchor A, and the other must be configured with the gA2BInitiator_d macro set to 0, called Car Anchor B. Car Anchor A triggers the EdgeLock-to-EdgeLock (E2E) key derivation and local IRK synchronization. Therefore, it should be started up after Car Anchor B.



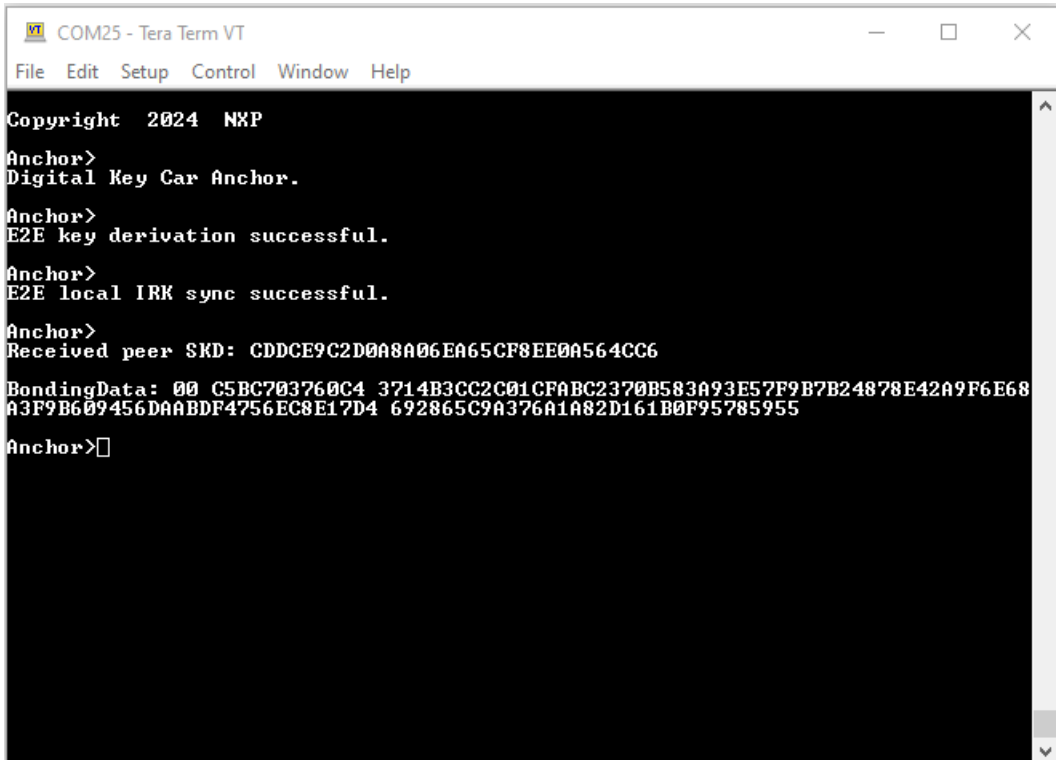
Demo steps:

- Start Car Anchor B, then Car Anchor A. At initialization the E2E key is derived and the local IRK of Car Anchor A is sent as a secure blob to Car Anchor B in order for both Car Anchors to have the same local IRK as shown in the Figure 1 and Figure 2.

Car Anchor A starts up, derives the E2E key and syncs with Car Anchor B

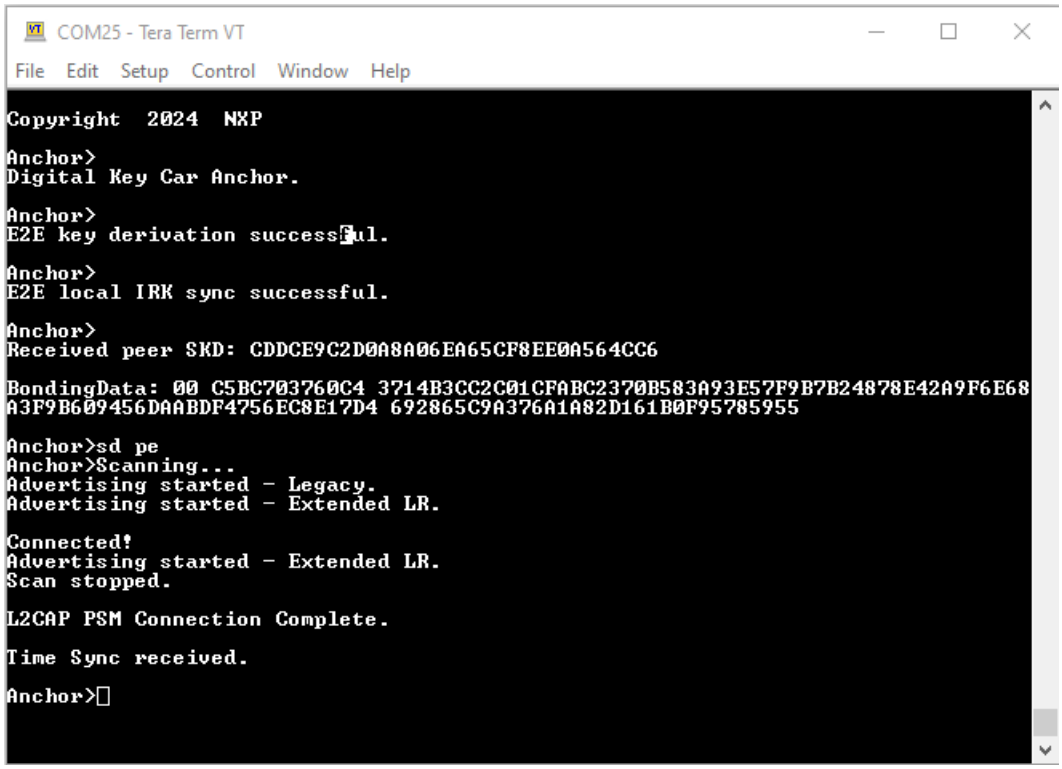


Car Anchor B starts up and syncs with Car Anchor B



- Trigger the Owner Pairing scenario by sending the "sd" command on the Device and "sd op" on Car Anchor A. Once the bond is created, the Bonding Data containing secured blobs for the LTK and peer IRK is sent to Car Anchor B. The Car Anchors display the Bonding Data in shell with the LTK in blob form (the LTK is never available in plain text) and the peer IRK in plain text. Now both Car Anchors have the same Bonding Data. Refer Figure 3 and Figure 4.

Car Anchor A pairs with Device



Car Anchor B has received the Bonding Data via the serial interface

- Disconnect Car Anchor A by sending the "dcnt" command.
- Once Car Anchor A is disconnected, send "sd" on the Device and "sd pe" on Car Anchor B. Car Anchor B is now able to perform a Passive Entry connection, without pairing as shown in Figure 5.

Car Anchor B performs Passive Entry

Running Passive Entry Scenario with Decision Based Advertising Filtering (DBAF) Decision Based Advertising Filtering can be used in the Passive Entry scenario. Using DBAF optimizes the scanning operation performed by the Digital Key Device of the advertisements sent by the Digital Key Car Anchor devices. This is accomplished by using 'ADV_DECISION_IND' PDUs, which contain the advertising address in the extended header. Using these PDUs allows the scanner to perform address resolution without the need to retrieve the AUX_ADV_IND PDU sent on the data channels.

The DBAF feature is supported on the following platforms:

- KW45B41Z-EVK
- KW47-EVK

Enabling DBAF To enable DBAF, modify the Digital Key applications as per the steps listed below:

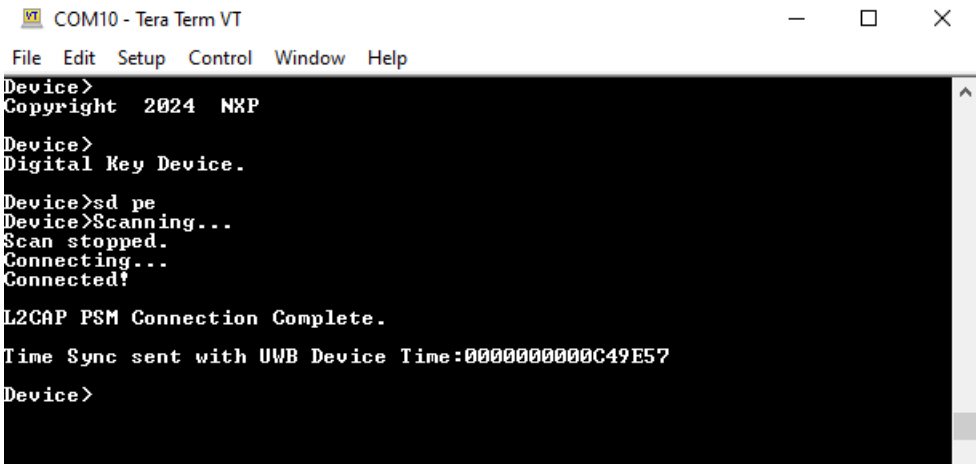
- (Required only for KW45B41Z-EVK): Flash the kw45b41_nbu_ble_xp_hosted NBU found in middleware/wireless/ble_controller/bin/experimental/.

For all platforms:

- Update the application project so that it uses the experimental Bluetooth LE Host library path: middleware/wireless/bluetooth/host/lib_exp/:
  - Use lib_ble_OPT_host_cm33_iar.a for the Digital Key Car Anchor application.
  - Use lib_ble_OPT_host_central_cm33_iar.a for the Digital Key Device application.
- In app_preinclude.h file, set gBLE60_DecisionBasedAdvertisingFilteringSupport_d to TRUE.
- Make the following updates in the digital_key_device.c (for the Digital Key Device application) and in app_digital_key_car_anchor.c (for the Digital Key Car Anchor application):

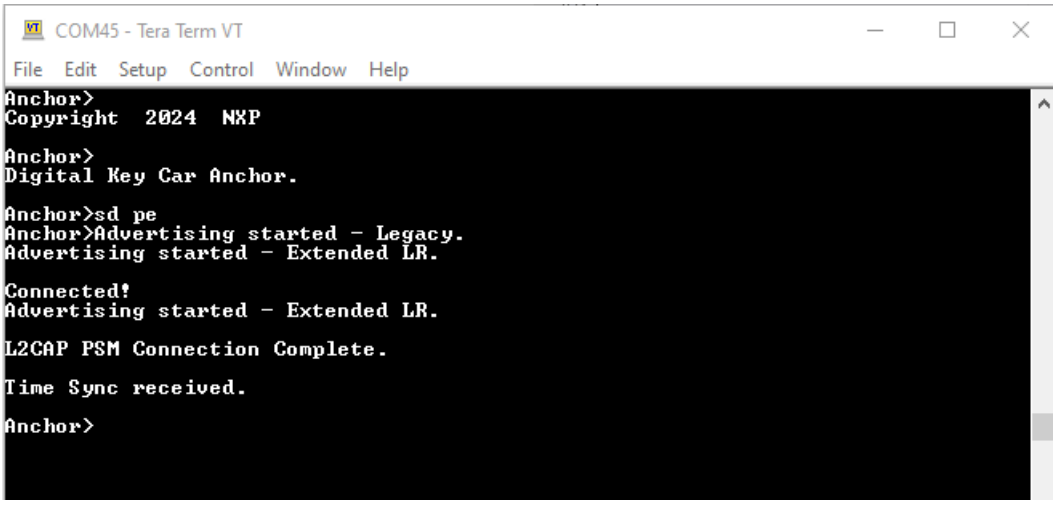
```
extern uint8_t gHostInitExpmFeatures;
#define gExpmDecisionBasedAdvertisingFilteringBit_d BIT1;
```

- In the function BluetoothLEHost_AppInit(), add the below line prior to the BluetoothLEHost_Init() function call:



```
gHostInitExpmFeatures |= gExpmDecisionBasedAdvertisingFilteringBit_d;
```

Parent topic:*Running Passive Entry Scenario with Decision Based Advertising Filtering (DBAF)*



Running the Passive Entry with DBAF scenario The Passive Entry with DBAF scenario runs after Owner Pairing between a Car Anchor and a Device successfully completes.

1. To run the Passive Entry with DBAF demo, reset the recently paired boards using either the **RST** switch or the "reset" command in the shell. Do NOT perform a factory reset, as this removes the bonding information from non-volatile memory.
2. After reset, run the "sd pe" command on the Car Anchor and "sd pe" command on the Device as shown in Figure 1 and Figure 2.

Passive Entry with DBAF on Device

Passive Entry with DBAF on Car Anchor

After following these steps, the Passive Entry scenario as described in Passive Entry Scenario runs.

Parent topic:*Running Passive Entry Scenario with Decision Based Advertising Filtering (DBAF)*

Intrusion Detection System The Intrusion Detection System (IDS) is a proprietary feature which allows the Car Anchor to monitor anomalous events related to the traffic and conditions

generated during the operation of the Bluetooth LE software stack. These events are detected at Host and Controller level. The application registers a callback where it receives and handles reports.

The IDS feature is supported on the following platforms:

- KW45B41Z-EVK
- KW47-EVK

To enable IDS, modify the Digital Key Car Anchor as per the steps listed below:

- Update the application project so that it uses the experimental Bluetooth LE Host library path: middleware/wireless/bluetooth/host/lib_exp/.
- In app_preinclude.h file, set gIntrusionDetectionSystem_d to TRUE.

Bluetooth Low Energy Host Stack FSCI Application Programming Kinetis FSCI Host Application Programming Interface

About This Document This document provides a detailed description for the Host Application Programming Interface (Host API) implementing the Framework Serial Connectivity Interface (FSCI) on a peripheral port such as UART, USB, and SPI. The Host API can be deployed from a PC tool or a host processor to perform control and monitoring of a wireless protocol stack running on the microcontroller. The software modules and libraries implementing the Host API is the Host Software Development Kit (SDK).

This version of the document describes the Bluetooth® Low Energy stack running on the Wireless Connectivity Microcontrollers (MCUs), which are interfaced from a high-level OS (Linux® OS, Windows® OS) by the Host API and the Host SDK.

Audience

This document is for software developers who create tools and multichip partitioned systems using a serial interface to a Bluetooth LE *black box* firmware running on a microcontroller.

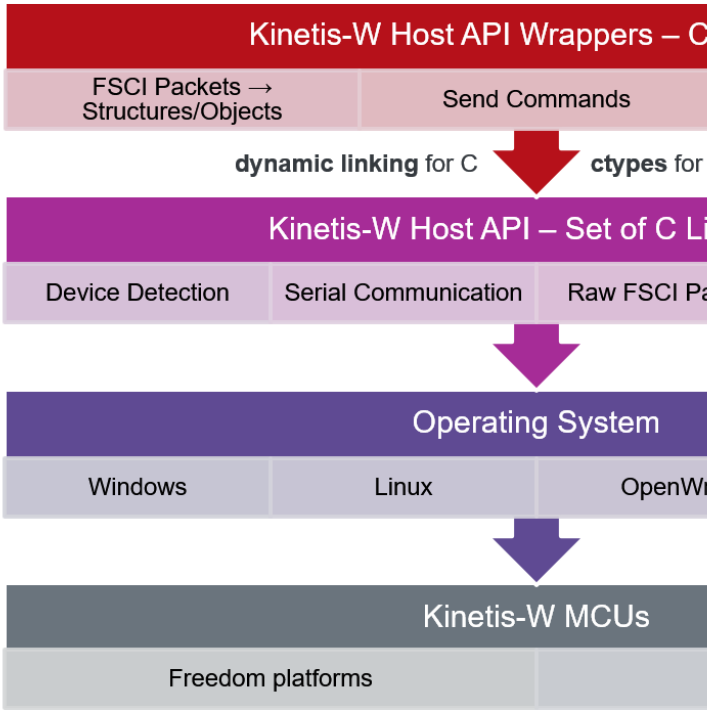
Parent topic: *Bluetooth Low Energy Host Stack FSCI Application Programming*

Deploying Host Controlled Firmware IAR Embedded Workbench for Arm® (EWARM) and MCUXpresso IDE are the development toolchains used to deploy the Bluetooth LE host stack software applications.

Detailed information about how to build, deploy and debug an IAR or MCUXpresso IDE-based project are presented in the *Bluetooth Low Energy Demo Applications User Guide*.

Bluetooth LE application configuration

To exercise the Host API, the Bluetooth LE *black box* firmware is required to be flashed on a compatible platform. The Bluetooth LE *black box* is represented by the ble_fscibb application firmware that can be interfaced and configured with FSCI commands over the serial interface.



The user can compile the *black box* image of the ble_fscibb software application using IAR Embedded Workbench for Arm (EWARM) or MCUXpresso IDE. For information on how to build the application see additional documentation provided in the package.

Parent topic: *Bluetooth Low Energy Host Stack FSCI Application Programming*

Host Software Overview The FSCI (Framework Serial Communication Interface) module allows interfacing the protocol stack with a host system or PC tool using a serial communication interface.

FSCI can be demonstrated using various host software, one being the set of Linux OS libraries exposing the Host API described in this document. The NXP Test Tool for Connectivity Products PC application is another interfacing tool, running on the Windows OS. Bluetooth LE stack makes use of XML files which contain detailed meta-descriptors for commands and events transported over the FSCI.

The FSCI module is explained in the Wireless Framework - Services - FSCI documentation.

```

Device detection The Wireless Host SDK can detect every USB attached peripheral device to a PC. On Linux OS, this is done via udev. Udev is the device manager for the Linux OS kernel and was introduced in Linux OS 2.5. Using the manager, the Wireless Host API can provide the Linux OS path for a device (for example, /dev/ttyACM0) and whether the device is a supported USB device, based on the vendor ID/product ID advertised. Upon device insertion, the USB cdc_acm kernel module is triggered by the kernel for interaction with TWR, USB and FRDM devices.

On Windows OS, attached peripherals are retrieved from the registry path HKEY_LOCAL_MACHINE\HARDWARE\DEVICEMAP\SERIALCOMM, resulting in names such as *COMxx* which must be used as input strings for the Python scripts which require a device name.

Serial port configuration The Host SDK configures a serial UART port with the following default values:

Host SDK – UART default values

Configuration	Value
Baudrate	115200
ByteSize	EIGHTBITS
StopBits	ONE_STOPBIT
PARITY	NO_PARITY
HandleDSRControl	0
HandleDTRControl	ENABLEDTR
HandleRTSControl	ENABLERTS
InX	0
OutCtsFlow	1
OutDSRFlow	1
OutX	0

The library only allows the possibility to change the baudrate, as this is the most common scenario.

> **NOTE**: For devices using a USB connection interfaced directly (where the USB stack runs on the device and the system is NOT using an OpenSDA UART to USB converter), the baudrate is not necessary and setting it has no effect.

The Host SDK configures a serial SPI port with the following default values:

Host SDK – SPI default values

Configuration	Value
Transfer Mode	Mode SPI_MODE_0
Maximum SPI transfer speed (Hz)	1 MHz
Bits per word	8

The library only allows the possibility to change the maximum SPI transfer speed.

Logger The Host SDK implements a logger functionality which is useful for debugging. Adding the compiler flag USE_LOGGER enables this functionality.

When running programs that make use of the Host SDK, a file named hsdk.log appears in the working directory. This is an excerpt from the log:

```
HSDK_INFO - [6684] [PhysicalDevice]InitPhysicalDevice:Allocated memory for PhysicalDevice
HSDK_INFO - [6684] [PhysicalDevice]InitPhysicalDevice:Initialized device's message queue
HSDK_INFO - [6684] [PhysicalDevice]InitPhysicalDevice:Created event manager for device
HSDK_INFO - [6684] [PhysicalDevice]InitPhysicalDevice:Created threadStart event

Linux OS Host Software Installation Guide

Libraries Prerequisites

Packages: build-essential, libudev, libudev-dev, libpcap, libpcap-dev. Use apt-get install on Debian-based distributions. The Linux OS kernel version must be greater than 3.2.

Installation

```
$ pwd
/home/user/hsdk
$ make
$ find build/ -name "\*.so"
build/libframer.so
build/libsys.so
build/libphysical.so
build/libuart.so
build/libfsci.so
build/libspi.so
$ sudo make install
```

By default, make generates sharedlibraries (having .so extension). The step make install (superuser privileges required) copies these libraries to /usr/local/lib, which is part of the default Linux OS library path. The installation prefix may be changed by passing the variable PREFIX, e.g. make install PREFIX=/usr/lib. The user is responsible for making sure that PREFIX is part of the system's LD_LIBRARY_PATH.

Static libraries can be generated instead, by modifying the LIB_OPTION variable in the Makefile from dynamic to static (.a extension).

make install also disables the ModemManager control for the connected devices. Otherwise, the daemon starts sending AT commands that affect the responsiveness of the afore-mentioned devices in the first 20 seconds after plug in.

Demos Installation

```
$ pwd
/home/user/hsdk/demo
$ make
$ ls bin/
GetKinetisDevices
```

These demos are provided in this package:

- GetKinetisDevices: this program detects the boards connected to the serial line and outputs the path to the console:

  ```
  $ ./GetKinetisDevices
  NXP Kinetis-W device on /dev/ttyACM0.
  NXP Kinetis-W device on /dev/ttyACM1.
  ```

Parent topic: *Bluetooth Low Energy Host Stack FSCI Application Programming*

Windows OS Host Software Installation Guide

Libraries Prerequisites

Microsoft Visual Studio® is required to build the host software. Open the solution file ConnectivityLibrary.sln and build it for either Win32 or x64, depending on your setup requirements. The output directory contains a file named HSDK.dll, which can be thought of as a bundle of all the shared libraries from Linux OS, except for SPI (libspi.so). Currently, SPI interface to the board is not supported by the Windows host software.

Prebuilt HSDK.dll files are available under directory hsdk-python\lib.

Installation

The host software for the Windows OS is designed to work in a Python environment by contrast to the Linux OS where standalone C demos also exist.

Download and install the Python 3.10.x/32b package from Python Downloads. When customizing the installation options, check Add python.exe to Path.

Using prebuilt library

1. Depending on your Python environment architure (not Windows architecture) copy the appropriate HSDK.dll from hsdk-python\lib\[x86|x64]to \<Python Directory\>\DLLs.
2. Download and install Visual C++ Redistributable Packages for Microsoft Visual Studio, depending on the Windows architecture of your system (vcredist_x86.exe or vcredist_x64.exe) from Microsoft Visual C++ Redistributable latest supported downloads.
3. Download and install the Microsoft Visual C++ Compiler for Python as described in the python Windows Complilers.

Using local built library

1. Depending on your Python environment architure (not Windows architecture), build the appropriate Microsoft Visual Studio solution configuration and then copy HSDK.dll to \<Python Directory\>\DLLs.
2. Download and install the Microsoft Visual C++ Compiler for Python as described in the python Windows Complilers.

Optionally, copy the hsdk\res\hsdk.conf to \<Python Directory\>\DLLs to control the behavior of the FSCI-ACK synchronization mechanism.

Demos See *Host API Python Bindings*.

Parent topic: *Bluetooth Low Energy Host Stack FSCI Application Programming*

Host API C Bindings The Host SDK includes a set of C bindings to interface with a *black-box*. Bindings are generated from the matching FSCI XML file that is available in the stack software package under tools\wireless\xml_fsci. The bindings are designed to be platform agnostic, with a minimal set of OS abstraction symbols required for building. Thus, the files can be easily integrated on a wide range of host platforms.

Directory Tree

```
hsdk-c/
  demo
    HeartRateSensor.c      Source file that implements the Bluetooth LE Heart Sensor Profile.
    Makefile
  inc
    ble_sig_defines.h      Standard Bluetooth SIG UUID values.
```

(continues on next page)

(continued from previous page)

```
    cmd_<name>.h          Generated from the matching FSCI <name>.xml file.
    os_abstraction.h      Provides OS dependent symbols for building the interface.
README.md
src
    cmd_<name>.c          Generated from the matching FSCI <name>.xml file.
    evt_<name>.c          Generated from the matching FSCI <name>.xml file.
    evt_printer_<name>.c  Generated from the matching FSCI <name>.xml file.
```

Tests and examples Tests and examples that make use of the C bindings are placed in the hsdk-c/demo directory. Example of usage:

```
$ cd hsdk-c/demo/
$ make
$ ./HeartRateSensor /dev/ttyACM0
[...]
--> Setup finished, please open IoT Toolbox -> Heart Rate -> HSDK_HRS
```

Development Header file cmd_<name>.h is generated from the corresponding <name>.xml FSCI XML file.

- Enumerations

```
/* Indicates whether the connection request is issued for a specific device or for all the devices in the␣
↪White List - default specific device */
typedef enum GAPConnectRequest_FilterPolicy_tag {
    GAPConnectRequest_FilterPolicy_gUseDeviceAddress_c = 0x00,
    GAPConnectRequest_FilterPolicy_gUseWhiteList_c     = 0x01
} GAPConnectRequest_FilterPolicy_t;
```

- Structures

```
typedef PACKED_STRUCT GAPConnectRequest_tag {
    uint16_t ScanInterval;          // Scanning interval - default 10ms
    uint16_t ScanWindow;            // Scanning window - default 10ms
    GAPConnectRequest_FilterPolicy_t FilterPolicy;          // Indicates whether the connection␣
↪request is issued for a specific device or for all the devices in the White List - default specific device
    GAPConnectRequest_OwnAddressType_t OwnAddressType;      // Indicates whether the address␣
↪used in connection requests will be the public address or the random address - default public address
    GAPConnectRequest_PeerAddressType_t PeerAddressType;    // When connecting to a specific␣
↪device, this indicates that device's address type - default public address
    uint8_t PeerAddress[6];       // When connecting to a specific device, this indicates that device's␣
↪address
    uint16_t ConnIntervalMin;       // The minimum desired connection interval - default 100ms
    uint16_t ConnIntervalMax;       // The maximum desired connection interval - default 200ms
    uint16_t ConnLatency;           // The desired connection latency (the maximum number of␣
↪consecutive connection events the Slave is allowed to ignore) - default 0
    uint16_t SupervisionTimeout;    // The maximum time interval between consecutive over-the-air␣
↪packets; if this timer expires, the connection is dropped - default 10s
    uint16_t ConnEventLengthMin;    // The minimum desired connection event length - default 0ms
    uint16_t ConnEventLengthMax;    // The maximum desired connection event length - default␣
↪maximum possible, ~41 s
    bool_t usePeerIdentityAddress;  // TRUE if the address defined in the peerAddressType and␣
↪peerAddress is an identity address
} GAPConnectRequest_t;
```

- Container for all possible event types

```
typedef struct bleEvtContainer_tag {
    uint16_t id;
    union {
        [...]
        GAPConnectionEventConnectedIndication_t GAPConnectionEventConnectedIndication;
        [...]
    } Data;
} bleEvtContainer_t;
```

- Prototypes for sending commands

```
memStatus_t GAPConnectRequest(GAPConnectRequest_t *req, void *arg, uint8_t fsciInterface);
```

Header file os_abstraction.h provides the required symbols for building the generated interface. When integrating in a project different that Host SDK, the user needs to provide the implementation for

```
void FSCI_transmitPayload (
    void *arg,              /* Optional argument passed to thefunction */
    uint8_t og,             /* FSCI operation group */
    uint8_t oc,             /* FSCI operation code */
    void *msg,              /* Pointer to payload */
    uint16_t msgLen,        /* Payload length */
    uint8_t fsciInterface   /* FSCI interface ID */
);
```

that creates and sends a FSCI packet (0x02 | og | oc | msgLen | msg | crc +- fsciInterface) on the serial interface. Source files cmd_<name>.c, evt_<name>.c and evt_printer_<name>.c are generated from the correspondent <NAME>.xml FSCI XML file.

- Functions that handle command serialization in cmd_<name>.c

```
memStatus_t GAPConnectRequest(GAPConnectRequest_t *req, void *arg, uint8_t fsciInterface) {
    /* Sanity check */
    if (!req)
    {
        return MEM_UNKNOWN_ERROR_c;
    }
    FSCI_transmitPayload(arg, 0x48, 0x1C, req, sizeof(GAPConnectRequest_t), fsciInterface);
    return MEM_SUCCESS_c;
}
```

- Event dispatcher in evt_<name>.c

```
void KHC_BLE_RX_MsgHandler(void *pData, void *param, uint8_t fsciInterface) {
    if (!pData || !param)
    {
        return;
    }

    fsciPacket_t *frame = (fsciPacket_t *)pData;
    bleEvtContainer_t *container = (bleEvtContainer_t *)param;
    uint8_t og = frame->opGroup;
    uint8_t oc = frame->opCode;
    uint8_t *pPayload = frame->data;
    uint16_t id = (og << 8) + oc, i;

    for (i = 0; i < sizeof(evtHandlerTbl) / sizeof(evtHandlerTbl[0]); i++)
    {
        if (evtHandlerTbl[i].id == id)
        {
            evtHandlerTbl[i].handlerFunc(container, pPayload);
```

(continues on next page)

(continued from previous page)

```
            break;
        }
    }
}
```

- Handler functions to perform event de-serialization in evt_<name>.c

```
static memStatus_t Load_GAPConnectionEventConnectedIndication(bleEvtContainer_t *container,␣
↪uint8_t *pPayload)
{
    GAPConnectionEventConnectedIndication_t *evt = &(container->Data.
↪GAPConnectionEventConnectedIndication);

    uint32_t idx = 0;

    /* Store (OG, OC) in ID */
    container->id = 0x489D;

    evt->DeviceId = pPayload[idx]; idx++;
    FLib_MemCpy(&(evt->ConnectionParameters.ConnInterval), pPayload + idx, sizeof(evt->
↪ConnectionParameters.ConnInterval)); idx += sizeof(evt->ConnectionParameters.ConnInterval);
    FLib_MemCpy(&(evt->ConnectionParameters.ConnLatency), pPayload + idx, sizeof(evt->
↪ConnectionParameters.ConnLatency)); idx += sizeof(evt->ConnectionParameters.ConnLatency);
    FLib_MemCpy(&(evt->ConnectionParameters.SupervisionTimeout), pPayload + idx, sizeof(evt->
↪ConnectionParameters.SupervisionTimeout)); idx += sizeof(evt->ConnectionParameters.
↪SupervisionTimeout);
    evt->ConnectionParameters.MasterClockAccuracy = (GAPConnectionEventConnectedIndication_
↪ConnectionParameters_MasterClockAccuracy_t)pPayload[idx]; idx++;
    evt->PeerAddressType = (GAPConnectionEventConnectedIndication_PeerAddressType_
↪t)pPayload[idx]; idx++;
    FLib_MemCpy(evt->PeerAddress, pPayload + idx, 6); idx += 6;
    evt->peerRpaResolved = (bool_t)pPayload[idx]; idx++;
    evt->localRpaUsed = (bool_t)pPayload[idx]; idx++;

    return MEM_SUCCESS_c;
}
```

- Event status console printer in evt_printer_<name>.c

```
void SHELL_BleEventNotify(void *param)
{
    bleEvtContainer_t *container = (bleEvtContainer_t *)param;

    switch (container->id) {
        [...]
        case 0x489D:
            shell_write("GAPConnectionEventConnectedIndication");
            shell_write(" -> ");
            switch (container->Data.GAPConnectionEventConnectedIndication.PeerAddressType)
            {
                case GAPConnectionEventConnectedIndication_PeerAddressType_gPublic_c:
                    shell_write(gPublic_c);
                    break;
                case GAPConnectionEventConnectedIndication_PeerAddressType_gRandom_c:
                    shell_write(gRandom_c);
                    break;
                default:
                    shell_printf("Unrecognized status 0x%02X", container->Data.
↪GAPConnectionEventConnectedIndication.PeerAddressType);
                    break;
            }
```

(continues on next page)

(continued from previous page)

```
            break;
        [...]
    }
}
```

Parent topic: *Bluetooth Low Energy Host Stack FSCI Application Programming*

Host API Python Bindings

Prerequisites Python 3.10.x/32b is necessary to run the Python bindings. The bindings use the Host API C libraries. On Linux and OS X operating systems, these are called from the installation location which is /usr/local/lib, while on Windows OS the library file is loaded in <Python Install Directory>\DLLs.

Platform setup To run scripts from the command line, the PYTHONPATH must be set accordingly, so that the interpreter can find the imported modules.

Linux OS

Adding the source folder to the PYTHONPATH can be done by editing ~/.bashrc and adding the following line:

```
export PYTHONPATH=\$PYTHONPATH:/home/.../hsdk-python/src
```

Most of the Python scripts operate on boards connected on a serial bus and superuser privileges must be employed to access the ports. After running a command prefixed with sudo, the environment paths become those of root, so the locally set PYTHONPATH is not visible anymore. That is why /etc/sudoers is modified to keep the environment variable when changing user.

Edit /etc/sudoers with your favorite text editor. Modify:

```
Defaults env_reset -> Defaults env_keep="PYTHONPATH"
```

As an alternative to avoid modifying the :sudoers file, the PYTHONPATH can be adjusted programmatically, as in the example below:

```
import sys

if sys.platform.startswith('linux'):
    sys.path.append('/home/user/hsdk-python/src')
```

Windows OS

Add the source folder to the PYTHONPATH by following these steps:

1. Navigate to My Computer > Properties > Advanced System Settings > Environment Variables > System Variables.
2. Modify existing or create new variable named PYTHONPATH, with the absolute path of tools\wireless\host_sdk\hsdk-python\src.

Directory Tree

```
lib                                 Compiled host SDK libraries for Windows.

Functional description The interaction between Python and the C libraries is made by the ctypes module. Ctypes provides C compatible data types, and allows calling functions in DLLs or shared libraries. It can be used to wrap these libraries in pure Python. Because the use of

shared libraries is a requirement, the LIB_OPTION variable must remain set on “dynamic” in hsdk/Makefile. Ctypes made into mainline Python starting with version 2.5.

The Python Bindings expose Bluetooth LE familiar API in the com.nxp.wireless_connectivity.commands package. Such a package contains the following modules:

```
bluetooth le
   enums.py          – Classes that resemble enums, constants are generated here.
   events.py         – Observer classes that can build an object from a byte array and deliver it to the user.
   frames.py         – Classes that map on Bluetooth LE/Firmware FSCI messages.
   operations.py     – Each Operation class encapsulates a request and one or multiple events that are to be␣
↪generated by the request.
   spec.py           – This file describes the name, size, order and relationship between the command␣
↪parameters.
   sync_requests.py  – Each Synchronous Request is a method which sends a request and returns the␣
↪triggered event.
```

Tests and examples are placed in the package com.nxp.wireless_connectivity.test.

Bluetooth LE Heart Rate Service use case The Heart Rate Service is presented as use case for using the API of a Bluetooth LE *black box*, located in the example hsdk-python/src/com/nxp/wireless_connectivity/test/hrs.py.

The example populates the GATT Database dynamically with the GATT, GAP, heart rate, battery and device information services. It then configures the Bluetooth LE stack and starts advertising. There are also two connect and disconnect observers to handle specific events.

The user needs to connect to the Bluetooth LE or hybrid *black box* through a serial bus port that is passed as a command line argument, for example, /dev/ttyACM0.

```
# python hrs.py -h
usage: hrs.py [-h] [-p] serial_port

Bluetooth LE demo app which implements a ble_fsci_heart_rate_sensor.

positional arguments:
   serial_port Kinetis-W system device node.
optional arguments:
   -h, --help  show this help message and exit
   -p, --pair  Use pairing
```

It is important to first execute a CPU reset request to the Bluetooth LE *black box* before performing any other configuration to reset the Buetooth LE stack. This is done by the following command:

```
FSCICPUReset(serial_port, protocol=Protocol.BLE)
```

User sync request example

It is recommended for the user to access the Bluetooth LE API through sync requests. GATTDBDynamicAddCharacteristicDeclarationAndValue API is used as an example:

```
def gattdb_dynamic_add_cdv(self, char_uuid, char_prop, maxval_len, initval, val_perm):
   '''
   Declare a characteristic and assign it a value.

   @param char_uuid: UUID of the characteristic
   @param char_prop: properties of the characteristic
   @param maxval_len: maximum length of the value
   @param initval: initial value
   @param val_perm: access permissions on the value
   @return: handle of the characteristic
```

(continues on next page)

(continued from previous page)

```
    '''
    ind = GATTDBDynamicAddCharacteristicDeclarationAndValue(
        self.serial_port,
        UuidType=UuidType.Uuid16Bits,
        Uuid=char_uuid,
        CharacteristicProperties=char_prop,
        MaxValueLength=maxval_len,
        InitialValueLength=len(initval),
        InitialValue=initval,
        ValueAccessPermissions=val_perm,
        protocol=self.protocol
    )
    if ind is None:
        return self.gattdb_dynamic_add_cdv(char_uuid, char_prop, maxval_len, initval, val_perm)

    print '\tCharacteristic Handle for UUID 0x%04X ->' % char_uuid, ind.CharacteristicHandle
    self.handles[char_uuid] = ind.CharacteristicHandle
    return ind.CharacteristicHandle
```

Sync request internal implementation

As an example, for the GATTDBDynamicAddCharacteristicDeclarationAndValue API, the command is executed through a synchronous request. The sync request code creates an object of the following class:

```
class GATTDBDynamicAddCharacteristicDeclarationAndValueRequest(object):

    def __init__(self,
UuidType=GATTDBDynamicAddCharacteristicDeclarationAndValueRequestUuidType.Uuid16Bits, Uuid=[],
CharacteristicProperties=GATTDBDynamicAddCharacteristicDeclarationAndValueRequestCharacteristicProperties.
↪gNone_c,
MaxValueLength=bytearray(2), InitialValueLength=bytearray(2), InitialValue=[],
ValueAccessPermissions=GATTDBDynamicAddCharacteristicDeclarationAndValueRequestValueAccessPermissions.
↪gPermissionNone_c):
    '''
    @param UuidType: UUID type
    @param Uuid: UUID value
    @param CharacteristicProperties: Characteristic properties
    @param MaxValueLength: If the Characteristic Value length is variable, this is the maximum length; for␣
↪fixed lengths this must be set to 0
    @param InitialValueLength: Value length at initialization; remains fixed if maxValueLength is set to 0,␣
↪otherwise cannot be greater than maxValueLength
    @param InitialValue: Contains the initial value of the Characteristic
    @param ValueAccessPermissions: Access permissions for the value attribute
    '''
    self.UuidType = UuidType
    self.Uuid = Uuid
    self.CharacteristicProperties = CharacteristicProperties
    self.MaxValueLength = MaxValueLength
    self.InitialValueLength = InitialValueLength
    self.InitialValue = InitialValue
    self.ValueAccessPermissions = ValueAccessPermissions
```

An operation is represented by an object of the following class:

```
class GATTDBDynamicAddCharacteristicDescriptorOperation(FsciOperation):

    def subscribeToEvents(self):
        self.spec = Spec.GATTDBDynamicAddCharacteristicDescriptorRequestFrame
        self.observers =[GATTDBDynamicAddCharacteristicDescriptorIndicationObserver(
↪'GATTDBDynamicAddCharacteristicDescriptorIndication'), ]
        super(GATTDBDynamicAddCharacteristicDescriptorOperation, self).subscribeToEvents()
```

The Spec object is initialized and set to zero in the FSCI packet any parameter not passed through the object of a class, depending on its length. Also, when defining such an object, the parameters may take simple integer, boolean or even list values instead of byte arrays, the values are serialized as a byte stream.

The observer is an object of the following class:

```
class GATTDBDynamicAddCharacteristicDeclarationAndValueIndicationObserver(Observer):
    opGroup = Spec.GATTDBDynamicAddCharacteristicDeclarationAndValueIndicationFrame.opGroup
    opCode = Spec.GATTDBDynamicAddCharacteristicDeclarationAndValueIndicationFrame.opCode

    @overrides(Observer)
    def observeEvent(self, framer, event, callback, sync_request):
    # Call super, print common information
    Observer.observeEvent(self, framer, event, callback, sync_request)
    #Get payload
    fsciFrame = cast(event, POINTER(FsciFrame))
    data = cast(fsciFrame.contents.data, POINTER(fsciFrame.contents.length * c_uint8))
    packet = Spec.GATTDBDynamicAddCharacteristicDeclarationAndValueIndicationFrame.
↪getFsciPacketFromByteArray(data.contents, fsciFrame.contents.length)
    # Create frame object
    frame = GATTDBDynamicAddCharacteristicDeclarationAndValueIndication()
    frame.CharacteristicHandle = packet.getParamValueAsNumber("CharacteristicHandle")
    framer.event_queue.put(frame) if sync_request else None

    if callback is not None:
        callback(frame)
    else:
        print_event(self.deviceName, frame)
    fsciLibrary.DestroyFSCIFrame(event)
```

The status of the request is printed at the console by the following general status handler:

```
def subscribe_to_async_ble_events_from(device, ack_policy=FsciAckPolicy.GLOBAL):
    ble_events = [
        L2CAPConfirmObserver('L2CAPConfirm'),
        GAPConfirmObserver('GAPConfirm'),
        GATTConfirmObserver('GATTConfirm'),
        GATTDBConfirmObserver('GATTDBConfirm'),
        GAPGenericEventInitializationCompleteIndicationObserver(
↪'GAPGenericEventInitializationCompleteIndication'),
        GAPAdvertisingEventCommandFailedIndicationObserver(
↪'GAPAdvertisingEventCommandFailedIndication'),
        GATTServerErrorIndicationObserver('GATTServerErrorIndication'),
        GATTServerCharacteristicCccdWrittenIndicationObserver(
↪'GATTServerCharacteristicCccdWrittenIndication')
    ]

    for ble_event in ble_events:
        FsciFramer(device, FsciAckPolicy.GLOBAL, Protocol.BLE, Baudrate.BR115200).addObserver(ble_
↪event)
```

Connect and disconnect observers

The following code adds observers for the connect and disconnect events in the user class:

```
class BLEDevice(object):
    '''
    Class which defines the actions performed on a generic Bluetooth LE device.
    Services implemented: GATT, GAP, Device Info.
    '''
    self.framer.addObserver(
        GAPConnectionEventConnectedIndicationObserver('GAPConnectionEventConnectedIndication'),
```

(continues on next page)

(continued from previous page)

```
        self.cb_gap_conn_event_connected_cb)
    self.framer.addObserver(GAPConnectionEventDisconnectedIndicationObserver(
↪'GAPConnectionEventDisconnectedIndication'),
    self.cb_gap_conn_event_disconnected_cb)
```

where the callbacks are:

```
def cb_gap_conn_event_connected_cb(self, event):
    '''
    Callback executed when a smartphone connects to this device.
    @param event: GAPConnectionEventConnectedIndication
    '''
    print_event(self.serial_port, event)
    self.client_device_id = event.DeviceId
    self.gap_event_connected.set()

def cb_gap_conn_event_disconnected_cb(self, event):
    '''
    Callback executed when a smartphone disconnects from this device.
    @param event: GAPConnectionEventdisConnectedIndication
    '''
    print_event(self.serial_port, event)
    self.gap_event_connected.clear()
```

From an Android™ or iOS-based smartphone, the user can use the Bluetooth LE Toolbox application in the Heart Rate profile. Random heart rate measurements in the range 60-100 are displayed every second, while battery values change every 10 seconds.

Parent topic: *Bluetooth Low Energy Host Stack FSCI Application Programming*

FSCI Messages XML

Overview The Framework Serial Communication Interface (FSCI) module supports interfacing the BLE Host Stack with a host or a PC tool (Test Tool for Connectivity Products) using a serial communication line. If the FSCI is used with the NXP Test Tool for Connectivity products, the tool can use an XML file containing a detailed meta-description for serial commands and events. This XML file is provided in the software packages that include this document.

Bluetooth LE Host Stack interface set

The Bluetooth LE Host Stack layers that offer access using FSCI are L2CAP, L2CAP CB, GATT, GATTDB, GAP, FSCI, and NVM. Each layer provides primitives that an upper layer (profile/application) uses to access services of that layer. This document includes a detailed list of the provided primitives.

Basic requirements

Following are the hardware requirements for using FSCI API RM:

- IAR Embedded Workbench for Arm architecture
- NXP development boards (to be loaded with the **ble_fscibb** application)
- Optional Bluetooth LE sniffer for testing
- PC tool (Test Tool for Connectivity Products) or another host processor capable of communicating through UART, USB, SPI, or I2C

FSCI message description This chapter describes the L2CAP, L2CAP CB, GATT, GATTDB, GAP, FSCI, and NVM commands (requests) and events (confirms and indications) in detail.

The BLE.xml document is found in the ble_fsci_app subfolder, and provides an XML representation of all these commands and events. The BLE_x.x.x.xml document is found in the ..\tools\wireless\xml_fsci\ subfolder, and provides an XML representation of all these commands and events.

How to interpret the XML

The XML is structured in <Commands> and <Events> tags, the contents grouped by layer. Each group contains the description <GroupDesc> and multiple <Cmd> tags (as shown below).

```
<BLE>
 <Commands>
  <L2CAP>
   <GroupDesc>L2CAP Commands</GroupDesc>
   <Cmd>
    <CmdName>L2CAP-Init.Request</CmdName>
    <CmdDesc>L2CAP initialization function</CmdDesc>
    <CmdHeader>41 01</CmdHeader>
    <CmdParms>
    </CmdParms>
   </Cmd>
  [...]
  </L2CAP>
  <L2CAPCB>
  [...]
  </L2CAPCB>
 [...]
 </Commands>
 <Events>
  [...]
 </Events>
 [...]
</BLE>
```

Every command or event is described in a <Cmd> that contains:

- the name - <CmdName>
- the description - <CmdDesc>
- the opGroup and opCode - <CmdHeader>
- the parameters - <CmdParms>

The parameters of a command/event are specified using the <Parm> tag and contain:

- the name - <ParmName>
- the description - <ParmDesc>
- the size - <ParmSize>
- the type - <ParmType>
- the last value - <ParmLastValue>
- the default value - <ParmDefaultValue>
- the type specifics - <ParmTypeSpecifics>

The type specifics tag is used where needed to specify certain behaviours:

- <ParmItem> for specifying *enum* items
- <ParmState> for specifying the state of a variable (e.g. *ReadOnly*)
- <ParmRange> for specifying the range of the values taken by a variable
- <Depend> for specifying a dependence on another variable (e.g.an *array*'s dependence on the length variable)

- <Parm> for specifying the parameters of a *struct*

FSCI message example For example, the L2CAP-SendAttData.Request command has the following XML structure:

```
<Cmd>
 <CmdName>L2CAP-SendAttData.Request</CmdName>
 <CmdDesc>Sends a data packet through ATT Channel</CmdDesc>
 <CmdHeader>41 03</CmdHeader>
 <CmdParms>
  <Parm>
   <ParmName>DeviceId</ParmName>
   <ParmDesc>The DeviceId for which the command is intended</ParmDesc>
   <ParmSize>1</ParmSize>
   <ParmType>tInt</ParmType>
   <ParmLastValue>00</ParmLastValue>
   <ParmDefaultValue>00</ParmDefaultValue>
  </Parm>
  <Parm>
   <ParmName>PacketLength</ParmName>
   <ParmDesc>Length of the ATT data packet to be sent</ParmDesc>
   <ParmSize>2</ParmSize>
   <ParmType>tInt</ParmType>
   <ParmLastValue>0001</ParmLastValue>
   <ParmDefaultValue>0001</ParmDefaultValue>
   <ParmTypeSpecifics>
    <ParmRange>0x0001-0xFFFF</ParmRange>
   </ParmTypeSpecifics>
  </Parm>
  <Parm>
   <ParmName>Packet</ParmName>
   <ParmDesc>The ATT data packet to be transmitted</ParmDesc>
   <ParmSize>1</ParmSize>
   <ParmType>tArray</ParmType>
   <ParmLastValue>00</ParmLastValue>
   <ParmDefaultValue>00</ParmDefaultValue>
   <ParmTypeSpecifics>
    <Depend>
     <DependName>PacketLength</DependName>
     <DependMask>0xFFFF</DependMask>
     <DependShift>0x0000</DependShift>
    </Depend>
   </ParmTypeSpecifics>
  </Parm>
 </CmdParms>
</Cmd>
```

This translates to:

Tag	Value	Description
<CmdName	L2CAP-SendAttData.Request	Name of the command/event
<CmdDesc	Sends a data packet through ATT Channel	Description of the command/event
<CmdHead	41 03	opGroup and opCode of the command/event in hexadecimal format
<CmdParm	<Parm>	List of the parameters used in the command/event
<ParmNam	DeviceId	Name of the parameter
<ParmDesc	The DeviceId for which the command is intended	Description of the parameter
<ParmSize	1	Parameter size (in bytes)
<ParmType	tInt	Type of the parameter
<ParmLast	00	Last value of the parameter in hexadecimal format
<ParmDefa	00	Default value of the parameter in hexadecimal format
<ParmType	<ParmRange>	Specify range of the parameter
	<Depend>	Specify dependency of the parameter “Packet” of type “tArray” of the variable <DependName> that is the PacketLength

Bluetooth Low Energy Connection Handover

Introduction Connection Handover is an NXP proprietary feature that enables a Bluetooth Low Energy connection to be seamlessly transferred from one device to another while the connected peer remains unaware.

This document explains how to integrate the NXP Bluetooth Low Energy Connection Handover feature in an application and provides detailed explanation of the most commonly used APIs and code examples.

Prerequisites The Bluetooth Low Energy Connection Handover feature can be integrated in an application that fulfills the following requirements:

- Supported platforms: KW45, KW47.
- Bluetooth Low Energy application that is using the lib_ble_OPT_host_cm33_iar.a host library.
- Communication channel between the Source and Target devices involved in the Connection Handover procedure.

Integration and APIs

Integration All the APIs referenced in this section are available in the connection handover library.

The available libraries are listed below:

- lib_ble_handover_cm33_iar.a (for IAR projects)
- lib_ble_handover_cm33_gcc.a (for MCUX or armgcc projects)

Parent topic:*Bluetooth LE Connection Handover Integration and APIs*

Connection Handover API availability

Gap_HandoverGetDataSize

```
bleResult_t Gap_HandoverGetDataSize(deviceId_t deviceId, uint32_t *pDataSize);
```

Description: Returns the size in octets of the Handover Data for the given peer device id.

Parameters:

- deviceId: Peer device identifier.
- pDataSize: Pointer to the size in octets of the Handover Data.

Returns: gBleSuccess_c or error.

Gap_HandoverGetData

```
bleResult_t Gap_HandoverGetData(deviceId_t deviceId, uint8_t *pData);
```

Description: Copies the data used by the Handover feature for the given peer device id.

Parameters:

- deviceId: Peer device identifier.
- pData: Pointer to memory location where the Handover data is to be copied.

Returns: gBleSuccess_c or error.

Gap_HandoverSetData

```
bleResult_t Gap_HandoverSetData(uint8_t *pData);
```

Description: Sets the data used by the Handover feature.

Parameters:

- pData: Pointer to memory location where the Handover data is found.

Returns: gBleSuccess_c or error.

Gap_HandoverSetLlPendingData

```
bleResult_t Gap_HandoverSetLlPendingData(uint16_t connectionHandle, uint8_t *pTxData);
```

Description: Sets the LL data pending on the target device to be transmitted after handover connect.

Parameters:

- connectionHandle: Handover connection identifier.
- pTxData: Pointer to memory location where the pending data is found.

Returns: gBleSuccess_c or error.

Gap_HandoverFreeData

```
bleResult_t Gap_HandoverFreeData(void);
```

Description: Frees reference to handover data provided through Gap_HandoverSetData().

Returns: gBleSuccess_c or gBleInvalidState_c if handover data reference is not set.

Gap_HandoverGetTime

```
bleResult_t Gap_HandoverGetTime(void);
```

Description: Gets timing information from Link Layer to be used in Handover process.

Returns: gBleSuccess_c or error.

Gap_HandoverSuspendTransmit

```
bleResult_t Gap_HandoverSuspendTransmit(deviceId_t deviceId, bleHandoverSuspendTransmitMode_t␣
↪mode, uint16_t eventCounter, uint8_t noOfConnIntervals);
```

Description: Suspends TX for the given connection.

Parameters:

- deviceId: Peer device identifier.
- mode: Mode.
- eventCounter: Event counter.
- noOfConnIntervals: Number of connection intervals during which TX is suspended. Use 0 for manual resume.

Returns: gBleSuccess_c or error.

Gap_HandoverResumeTransmit

```
bleResult_t Gap_HandoverResumeTransmit(deviceId_t deviceId);
```

Description: Resumes TX for the given connection.

Parameters:

- deviceId: Peer device identifier.

Returns: gBleSuccess_c or error.

Gap_HandoverAnchorNotification

```
bleResult_t Gap_HandoverAnchorNotification(deviceId_t deviceId, bleHandoverAnchorNotificationEnable_t
↪enable, uint8_t noOfReports);
```

Description: Enables or disables anchor notifications for the given peer.

Parameters:

- deviceId: Peer device identifier.
- enable: Enables or disables notifications.
- noOfReports: Number of reports to receive (0 for manual stop).

Returns: gBleSuccess_c or error.

Gap_HandoverAnchorSearchStart

```
bleResult_t Gap_HandoverAnchorSearchStart(gapHandoverAnchorSearchStartParams_t *pSearchParams);
```

Description: Starts anchor search with the given parameters.

Parameters:

- pSearchParams: Pointer to structure containing anchor search parameters. The structure contains:
  - startTime625: Slot of the anchor point timing of the connection event.
  - startTimeOffset: Slot offset of the anchor point timing of the connection event.
  - lastRxInstant: Last successful access address reception instant (unit 625 us).
  - accessAddress: Access address (4 bytes).
  - crcInit: CRC initialization value (3 bytes).
  - channelMap: Channel map (5 bytes, FF FF FF FF 1F if all channels are used).
  - connInterval: Connection interval (unit 1.25ms).
  - latency: Latency (unit connection interval).
  - supervisionTimeout: Supervision timeout (unit 10ms).
  - eventCounter: Current connection event counter.
  - centralSca: Sleep clock accuracy (0 to 7).
  - role: Role (0 for central and 1 for peripheral).
  - centralPhy: TX/RX PHY.
  - seqNum: Sequence number; bits 1-0: latest received SN and NESN; bits 5-4: latest transmitted SN and NESN.
  - hopAlgo2: Hop algorithm (0/1 for hop algorithm #1 or #2).
  - unmappedChannelIndex: Unmapped channel index (used only for hop algorithm #1).
  - hopIncrement: Hop increment.
  - ucNbReports: Number of connection intervals to monitor (0: continuous, 1-255: automatic stop).
  - uiEventCounterAdvance: Event counter delay to perform the search (0 to start ASAP).
  - timeout: Timeout in connection intervals (0 if no timeout).
  - timingDiffSlot: Slot difference of the LL timing.
  - timingDiffOffset: Slot offset difference of the LL timing.

  - mode: Search mode setting.

Returns: gBleSuccess_c or error.

Gap_HandoverAnchorSearchStop

```
bleResult_t Gap_HandoverAnchorSearchStop(uint16_t connHandle);
```

Description: Stops anchor search for the given connection handle.

Parameters:

- connHandle: Connection handle for which to stop the anchor search.

Returns: gBleSuccess_c or error.

Gap_HandoverTimeSyncTransmit

```
bleResult_t Gap_HandoverTimeSyncTransmit(gapHandoverTimeSyncTransmitParams_t *pTransmitParams);
```

Description: Starts time sync advertising with given parameters.

Parameters:

- pTransmitParams: Pointer to structure containing time sync transmit parameters. The structure contains:
  - enable: Enables or disables the transmit operation (0 = disable, 1 = enable).
  - advChannel: BLE channel to use for advertising (0 to 39).
  - deviceAddress: Packet identifier, can be the BD address or any value (6 bytes).
  - phys: PHY setting (0 = 1M, 1 = 2M, 2 = LR S8, 3 = LR S2).
  - txPowerLevel: TX Power level (0 to 31).
  - txIntervalSlots625: Packet interval in slots (4 to 255).

Returns: gBleSuccess_c or error.

Gap_HandoverTimeSyncReceive

```
bleResult_t Gap_HandoverTimeSyncReceive(gapHandoverTimeSyncReceiveParams_t *pReceiveParams);
```

Description: Starts time sync scanning with the given parameters.

Parameters:

- pReceiveParams: Pointer to structure containing time sync receive parameters. The structure contains:
  - enable: Enables or disables the receive operation (0 = disable, 1 = enable).
  - scanChannel: BLE channel to use for scanning (0 to 39).
  - deviceAddress: Packet identifier, can be the BD address or any value (6 bytes).
  - phys: PHY setting (0 = 1M, 1 = 2M, 2 = LR S8, 3 = LR S2).
  - stopWhenFound: One-shot setting (0 = continue scanning, 1 = stop when packet is found).

Returns: gBleSuccess_c or error.

Gap_HandoverGetConnParams

```
bleResult_t Gap_HandoverGetConnParams(uint16_t connHandle, gapConnectionCallback_t
↪connectionCallback, uint8_t anchorNotification);
```

Description: Connects to a peer device initialized through the Connection Handover procedure.

Parameters:

- connHandle: Handover Connection handle.
- connectionCallback: Pointer to the connection event handler function.
- anchorNotification: Anchor search setting after handover, 0 - stop anchor notification, 1 - keep anchor notification.

Returns: gBleSuccess_c or error.

Gap_HandoverDisconnect

```
bleResult_t Gap_HandoverDisconnect(deviceId_t deviceId);
```

Description: Disconnects a peer device for which the connection was handed over to another device.

Parameters:

- deviceId: Peer device identifier.

Returns: gBleSuccess_c or error.

Gap_HandoverInit

```
bleResult_t Gap_HandoverInit(void);
```

Description: Initializes the connection handover feature. Must be called before Ble_Initialize().

Returns: gBleInvalidState_c if Ble_Initialize() was already called, gBleSuccess_c otherwise.

Gap_HandoverSetSkd

```
bleResult_t Gap_HandoverSetSkd(uint8_t nvmIndex, uint8_t *pSkd);
```

Description: Sets the SKD of the connection that is to be handed over. Used only if gAppSecureMode_d is enabled in the application. Requires Handover Data to be set.

Parameters:

- nvmIndex: Bonding Data NVM index.
- pSkd: Pointer to 16 octets SKD.

Returns: gBleInvalidState_c if Ble_Initialize() was already called, gBleSuccess_c otherwise.

Gap_HandoverGetCsLlContext

```
bleResult_t Gap_HandoverGetCsLlContext(deviceId_t deviceId);
```

Description: Copies the LL CS-related context data for the given peer device id.

Parameters:

- deviceId: Peer device identifier.

Returns: gBleSuccess_c or error.

Gap_HandoverSetCsLlContext

```
bleResult_t Gap_HandoverSetCsLlContext(deviceId_t deviceId, uint16_t mask, uint8_t contextLength,␣
↪uint8_t *pContextData);
```

Description: Sets the CS-related context data into the LL, for the given peer device id.

Parameters:

- deviceId: Peer device identifier.
- mask: Context data bitmask (used by the LL).
- contextLength: Length of the context data.
- pContextData: Pointer to context data.

Returns: gBleSuccess_c or error.

Gap_HandoverUpdateConnParams

```
bleResult_t Gap_HandoverUpdateConnParams(gapHandoverUpdateConnParams_t *pConnParams);
```

Description: Updates the channel map and/or PHY used in the current anchor monitoring process.

Parameters:

- pConnParams: Pointer to connection parameters to be updated.

Returns: gBleSuccess_c or error.

Gap_HandoverApplyConnectionUpdateProcedure

```
bleResult_t Gap_
↪HandoverApplyConnectionUpdateProcedure(gapHandoverApplyConnectionUpdateProcedure_t␣
↪*pConnParams);
```

Description: Applies the new connection parameters in case of Connection Update Procedure on the active controller.

Parameters:

- pConnParams: Pointer to connection parameters to be applied.

Returns: gBleSuccess_c or error.

Connection Handover Events

The following events can be received through the GAP generic callback during the handover operations:

gHandoverGetComplete_c (0x31)

Description: Event generated when handover data get operation is complete.

Event Data: handoverGetData_t containing:

- status: Command status.
- pData: Pointer to connection handover data.

gHandoverSetComplete_c (0x32) **Description**: Event generated when handover data set operation is complete.

Event Data: handoverSetData_t containing:

- status: Command status.
- pData: Pointer to connection handover data.

gHandoverGetCsLlContextComplete_c (0x33) **Description**: Event generated when handover CS LL context data get operation is complete.

Event Data: handoverGetCsLlContext_t containing:

- status: Command status.
- responseMask: LL context bitmap indicating the Channel Sounding context.
- llContextLength: Context data length.
- llContext: LL Context data.

gHandoverSetCsLlContextComplete_c (0x34) **Description**: Event generated when handover CS LL context data set operation is complete.

Event Data: Status of the operation.

gHandoverGetTime_c (0x35) **Description**: Event generated when Handover Get Time command is complete.

Event Data: handoverGetTime_t containing:

- status: Command status.
- slot: LL timing slot counter (unit 625us).
- us_offset: LL timing slot offset (0 to 624, unit us).

gHandoverSuspendTransmitComplete_c (0x36) **Description**: Event generated when Handover Suspend Transmit command is complete.

Event Data: handoverSuspendTransmitCompleteEvent_t containing:

- connectionHandle: Connection identifier.
- noOfPendingAclPackets: Number of pending ACL packets.
- sizeOfPendingAclPackets: Pending ACL packet data size.
- sizeOfDataTxInOldestPacket: Size of data transmitted and acked in the oldest ACL packet.
- sizeOfDataNAckInOldestPacket: Size of data transmitted but not acked in the oldest ACL packet.

gHandoverResumeTransmitComplete_c (0x37) **Description**: Event generated when Handover Resume Transmit command is complete.

Event Data: handoverResumeTransmitCompleteEvent_t containing:

- connectionHandle: Connection identifier.

gHandoverAnchorNotificationStateChanged_c (0x38) **Description**: Event generated when Handover Anchor Notification command is complete.

Event Data: handoverAnchorNotificationStateChanged_t containing:

- connectionHandle: Connection identifier.

gHandoverAnchorSearchStarted_c (0x39) **Description**: Event generated when Handover Anchor Search Start command is complete.

Event Data: handoverAnchorSearchStart_t containing:

- status: Command status.
- connectionHandle: Connection identifier.

gHandoverAnchorSearchStopped_c (0x3A) **Description**: Event generated when Handover Anchor Search Stop command is complete.

Event Data: handoverAnchorSearchStop_t containing:

- status: Command status.
- connectionHandle: Connection identifier.

gHandoverTimeSyncTransmitStateChanged_c (0x3B) **Description**: Event generated when Handover Time Sync Transmit command is complete.

Event Data: Status of the operation.

gHandoverTimeSyncReceiveComplete_c (0x3C) **Description**: Event generated when Handover Time Sync Receive command is complete.

Event Data: Status of the operation.

gHandoverAnchorMonitorEvent_c (0x3D) **Description**: Event received from Controller - Handover Anchor Monitor.

Event Data: handoverAnchorMonitorEvent_t containing:

- connectionHandle: Connection identifier.
- connEvent: Current connection event counter.
- rssiRemote: RSSI of the packet from the remote device (+127 if not available).
- lqiRemote: LQI (Link Quality Indicator) of the packet from the remote device.
- statusRemote: Status of the packet from the remote device.
- rssiActive: RSSI of the packet from the active device (+127 if not available).
- lqiActive: LQI (Link Quality Indicator) of the packet from the active device.
- statusActive: Status of the packet from the active device.
- anchorClock625Us: Slot of the anchor point timing of the connection event.
- anchorDelay: Slot offset of the anchor point timing of the connection event.
- chIdx: BLE channel index.
- ucNbReports: Number of remaining reports to receive.

gHandoverTimeSyncEvent_c (0x3E) **Description**: Event received from Controller - Handover Time Sync.

Event Data: handoverTimeSyncEvent_t containing:

- txClkSlot: Transmitter packet start time in slot (625 us).
- txUs: Transmitter packet start time offset inside the slot (0 to 624 us).
- rxClkSlot: Receiver packet start time in slot (625 us).
- rxUs: Receiver packet start time offset inside the slot (0 to 624 us).
- rssi: RSSI value.

gHandoverConnParamUpdateEvent_c (0x3F) **Description**: Event received from Controller - Handover Connection Parameters Update.

Event Data: handoverConnParamUpdateEvent_t containing:

- status: Status indicating the event trigger source.
- connectionHandle: Connection identifier.
- ulTxAccCode: Access address.
- aCrcInitVal: CRC initialization value (3 bytes).
- uiConnInterval: Connection interval (unit 1.25ms).
- uiSuperTO: Supervision timeout (unit 10ms).
- uiConnLatency: Latency (unit connection interval).
- aChMapBm: Channel map (5 bytes).
- ucChannelSelection: Hop algorithm (0/1 for algorithm #1 or #2).
- ucHop: Hop increment.
- ucUnMapChIdx: Unmapped channel index.
- ucCentralSca: Sleep clock accuracy.
- ucRole: Role (0 for central and 1 for peripheral).
- aucRemoteMasRxPHY: TX/RX PHY.
- seqNum: Sequence number.
- uiConnEvent: Current connection event counter.
- ulAnchorClk: Slot of the anchor point timing.
- uiAnchorDelay: Slot offset of the anchor point timing.
- ulRxInstant: Last successful access address reception instant.

gHandoverFreeComplete_c (0x46) **Description**: Event generated when handover data free operation is complete.

Event Data: Status of the operation.

gHandoverUpdateConnParamsComplete_c (0x47) **Description**: Event generated when Handover Update Connection Parameters command is complete.

Event Data: handoverUpdateConnParams_t containing:

- status: Command status.

- connectionHandle: Connection identifier.

gHandoverLlPendingData_c (0x4A) **Description**: Event indicating ACL Data pending to be transmitted by the LL.

Event Data: handoverLlPendingDataIndication_t containing:

- dataSize: Pending HCI ACL data packet size.
- pData: Pointer to message containing the HCI ACL data packet (should be freed by the application).

gHandoverAnchorMonitorPacketEvent_c (0x44) **Description**: Event received from Controller - Handover Anchor Monitor Packet.

Event Data: handoverAnchorMonitorPacketEvent_t containing:

- packetCounter: Packet counter, incremented for each event.
- connectionHandle: Connection identifier.
- statusPacket: Status of the packet.
- phy: PHY (0/1/2/3 for 1M/2M/LR S8/LR S2).
- chIdx: BLE channel index.
- rssiPacket: RSSI of the packet (+127 if not available).
- lqiPacket: LQI (Link Quality Indicator) of the packet.
- connEvent: Current connection event counter.
- anchorClock625Us: Slot value of packet start time (in 625us unit).
- anchorDelay: Slot offset value of packet start time (in 1us unit).
- ucNbConnIntervals: Number of remaining connection intervals to monitor.
- pduSize: PDU length.
- pPdu: Pointer to PDU data (must be freed by the application).

gHandoverAnchorMonitorPacketContinueEvent_c (0x45) **Description**: Event received from Controller - Handover Anchor Monitor Packet Continue.

Event Data: handoverAnchorMonitorPacketContinueEvent_t containing:

- packetCounter: Packet counter, incremented for each event.
- connectionHandle: Connection identifier.
- pduSize: PDU length.
- pPdu: Pointer to PDU data (must be freed by the application).

gHandoverConnectionUpdateProcedureEvent_c (0x4F) **Description**: Event reporting new connection parameters indicated during the Connection Update procedure.

Event Data: handoverConnectionUpdateProcedureEvent_t containing:

- connectionHandle: Connection identifier.
- winSize: Transmit window size value (in 1.25 ms units).
- winOffset: Transmit window offset value (in 1.25 ms units).
- interval: Connection interval value (in 1.25 ms units).

- latency: Connection peripheral latency value.
- timeout: Connection supervision timeout value (in 10 ms units).
- instant: Connection event counter value when new parameters will be applied.
- currentEventCounter: Current connection event counter.

gHandoverApplyConnectionUpdateProcedureComplete_c (0x50) **Description**: Event reporting completion of the Connection Update procedure application.

Event Data: handoverApplyConnectionUpdateProcedure_t containing:

- connectionHandle: Connection identifier.

Application common modules The following application common modules are meant to offer a simplified API for generic Connection Handover procedures and allow for quick integration into existing applications.

Handover application common module

Introduction The Connection Handover application common module allows for quick integration of the Connection Handover feature in a Bluetooth LE application.

Integration All the APIs referenced in this section are available in the Connection Handover application common module.

Connection handover requires a communication interface with the other devices involved in the connection handover process.

Perform the following steps to integrate Connection Handover in an application:

1. Add app_handover.c and app_handover.h from middleware\wireless\bluetooth\application\common\auto\ in the application project.
2. Initialize the Connection Handover application common module by calling AppHandover_Init().
3. Call AppHandover_ProcessA2ACommand() to handle connection handover commands received.
4. Call AppHandover_GenericCallback() in the application generic events callback to handle the following events:
   - gHandoverAnchorSearchStarted_c
   - gHandoverAnchorSearchStopped_c
   - gHandoverAnchorMonitorEvent_c
   - gHandoverSuspendTransmitComplete_c
   - gHandoverGetComplete_c
   - gGetConnParamsComplete_c
   - gHandoverTimeSyncEvent_c
   - gHandoverTimeSyncTransmitStateChanged_c
   - gHandoverTimeSyncReceiveComplete_c
   - gLlSkdReportEvent_c

- gInternalError_c
- gHandoverAnchorMonitorPacketEvent_c
- gHandoverAnchorMonitorPacketContinueEvent_c
- gHandoverFreeComplete_c
- gHandoverLlPendingData_c
- gHandoverConnectionUpdateProcedureEvent_c
- gHandoverApplyConnectionUpdateProcedureComplete_c

5. Call AppHandover_ConnectionCallback in the application connection events callback to handle the following events:
   - gConnEvtHandoverConnected_c
   - gHandoverDisconnected_c
6. To trigger connection handover call AppHandover_SetPeerDevice() followed by AppHandover_StartTimeSync()

Connection Handover application common module APIs

AppHandover_Init

```
bleResult_t AppHandover_Init(appHandoverEventCb_t pfAppEventCb, gapConnectionCallback_t␣
↪pfConnectionCallback, appHandoverA2AInterfaceCb_t pfAppA2AInterfaceCb);
```

Description: Initializes the handover application common module.

Parameters:

- pfAppEventCb: Application callback for handover events.
- pfConnectionCallback: Connection callback for connection events.
- pfAppA2AInterfaceCb: Communication callback for handover data.

Returns: bleResult_t

AppHandover_TimeSyncTransmit

```
bleResult_t AppHandover_TimeSyncTransmit(bleHandoverTimeSyncEnable_t enable);
```

Description: Enables/disables transmission of time synchronization information.

Parameters:

- enable: Enables or disables the transmission of time synchronization parameters.

Returns: bleResult_t

AppHandover_TimeSyncReceive

```
bleResult_t AppHandover_TimeSyncReceive(bleHandoverTimeSyncEnable_t enable);
```

Description: Enables/disables reception of time synchronization information.

Parameters:

- enable: Enables or disables the reception of time synchronization parameters.

Returns: bleResult_t

AppHandover_StartTimeSync

```
bleResult_t AppHandover_StartTimeSync(bool_t bTimeSyncForHandover);
```

Description: Triggers handover time synchronization.

Parameters:

- bTimeSyncForHandover: TRUE if handover is following, FALSE if RSSI sniffing is following.

Returns: bleResult_t

AppHandover_TimeSyncTransmitSetParams

```
void AppHandover_TimeSyncTransmitSetParams(gapHandoverTimeSyncTransmitParams_t *pParams);
```

Description: Sets parameters for the transmission of time synchronization information.

Parameters:

- pParams: Tx params.

Returns: None

AppHandover_TimeSyncReceiveSetParams

```
void AppHandover_TimeSyncReceiveSetParams(gapHandoverTimeSyncReceiveParams_t *pParams);
```

Description: Sets parameters for the reception of time synchronization information.

Parameters:

- pParams: Rx params.

Returns: None

AppHandover_SetPeerDevice

```
void AppHandover_SetPeerDevice(deviceId_t deviceId);
```

Description: Sets the peer device for connection handover.

Parameters:

- deviceId: Peer device identifier.

Returns: None

AppHandover_ProcessA2ACommand

```
void AppHandover_ProcessA2ACommand(uint8_t cmdId, uint32_t cmdLen, uint8_t *pCmdData);
```

Description: Processes handover commands.

Parameters:

- cmdId: Command identifier.
- cmdLen: Command length.
- pCmdData: Command data.

Returns: None

AppHandover_SetPeerSkd

```
bleResult_t AppHandover_SetPeerSkd(uint8_t *pSkd, uint8_t nvmIndex);
```

Description: Sets the peer LL SKD for connection handover with advanced secure mode.

Parameters:

- nvmIndex: Peer device NVM index.
- pSkd:

A2A application common module

Introduction The A2A (Anchor-to-Anchor) application common module implements a sample communication interface between devices involved in the connection handover process.

Integration Perform the following steps to integrate A2A application common module in an application:

1. Add app_a2a_interface.c and app_a2a_interface.h from middleware\wireless\bluetooth\application\common\auto\ in the application project.
2. Initialize the Connection Handover application common module by calling A2A_Init().
3. Use A2A_SendCommand() as the communication callback for the Connection Handover application common module.
4. Use A2A_SendSetBondingDataCommand() in the application to send the bonding data from the connected anchor to the target anchor after pairing a new device is successful.

A2A application common module APIs

A2A_Init

```
bleResult_t A2A_Init(serial_handle_t pSerialHandle, appA2ADataIndicationCb_t pfDataIndCb);
```

Description: Performs initialization of the Anchor to Anchor serial communication.

Parameters:

- pSerialHandle: Serial interface handle to be used for communication.
- pfConnectionCallback: Application callback for received packets.

Returns: bleResult_t

A2A_SendCommand

```
void A2A_SendCommand(uint8_t opGroup, uint8_t opCode, uint8_t *pPayload, uint16_t len);
```

Description: Send packet over the Anchor to Anchor interface.

Parameters:

- opGroup: Group identifier.
- opCode: Command identifier.
- pPayload: Pointer to command data.
- len: Command length.

Returns: None

A2B application common module

Introduction The A2B (Alice to Bob) application common module takes advantage of the Edge-Lock to EdgeLock Key Exchange feature of the EdgeLock Secure Enclave integrated in the KW45 and KW47 to derive a special internal key (E2E key) that may be used to import/export encrypted key material between two devices. This may be used to allow for secure transfer of the key material between the anchors involved in the Connection Handover process. The LTK and IRK included in the bonding data are transferred as encrypted blobs that may only be decrypted by the EdgeLock Secure Enclave of the destination device.

Integration Perform the following steps to integrate A2B application common module in an application:

1. Add app_a2b.c and app_a2b.h from middleware\wireless\bluetooth\application\common\auto\ in the application project.
2. Initialize the A2B application common module by calling A2B_Init().
3. One of the device involved in the Connection Handover process must be configured with the gA2BInitiator_d macro set to 1, the other must be configured with the gA2BInitiator_d macro set to 0. The initiator device triggers the EdgeLock-to-EdgeLock (E2E) key derivation and local IRK synchronization. Therefore, it should be started last.
4. After initialization the E2E key will be derived and the gSecLibFunctions.pfSecLib_ExportA2BBlob() and gSecLibFunctions.pfSecLib_ImportA2BBlob() functions can be used to export and import encrypted key material between the two devices.

A2B application common module APIs

A2B_Init

```
bleResult_t A2B_Init(appA2BEventCb_t pfAppEventCb, appA2BA2ACommInterfaceCb_t␣
↪pfAppA2AInterfaceCb);
```

Description: Trigger the A2B feature initialization by generating the public key used for the Edgelock to Edgelock key derivation.

Parameters:

- pfAppEventCb: Application callback functions for A2B events.
- pfAppA2AInterfaceCb: Communication callback for A2B data.

Returns: bleResult_t - Result of the operation.

A2B_ProcessA2ACommand

```
void A2B_ProcessA2ACommand(uint8_t cmdId, uint32_t cmdLen, uint8_t *pCmdData);
```

Description: Process A2B commands received through the A2A interface.

Parameters:

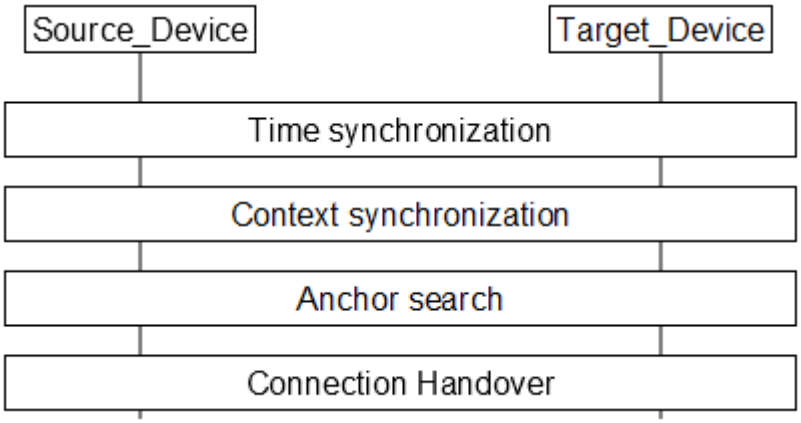
- cmdId: Command identifier.
- cmdLen: Command length.
- pCmdData: Command data.

Returns: None

A2B_FreeE2EKey

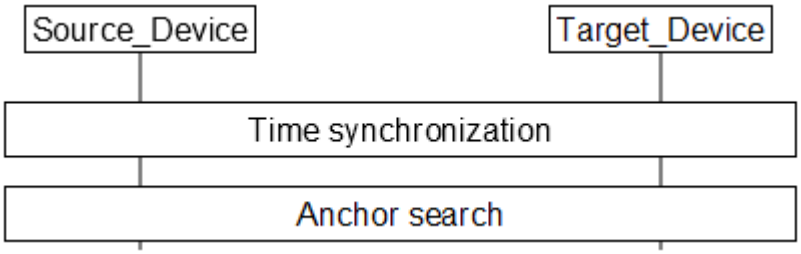
```
bleResult_t A2B_FreeE2EKey(void);
```

Description: Free the EdgeLock to EdgeLock key.



Parameters: None

Returns: bleResult_t - Result of the operation.



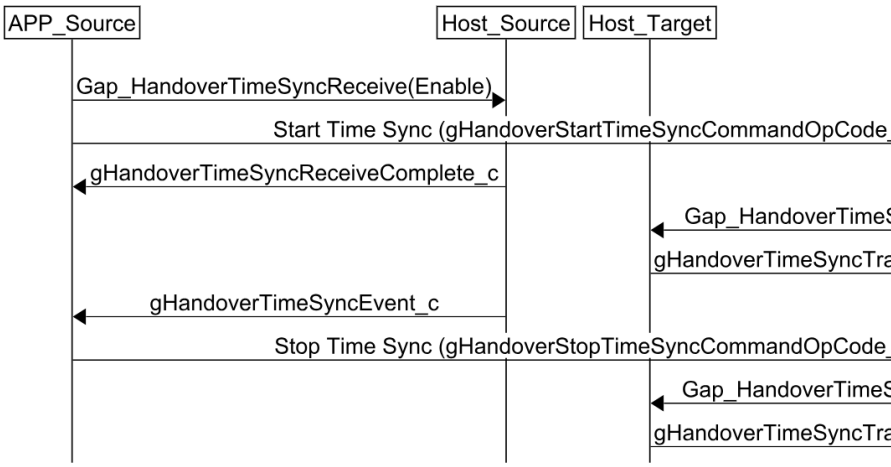
Procedures This section describes the available Connection Handover procedures. A procedure is executed between a device in a connection, referred as the Source device, and another device involved in the Connection Handover or Anchor/Packet Monitoring process, referred to as the Target device.

Procedures - Top level view The Connection Handover and Anchor/Packet Monitoring process comprises several procedures as illustrated below.

Connection Handover

Anchor/Packet monitoring

Individual procedures This section describes each individual procedure in detail.



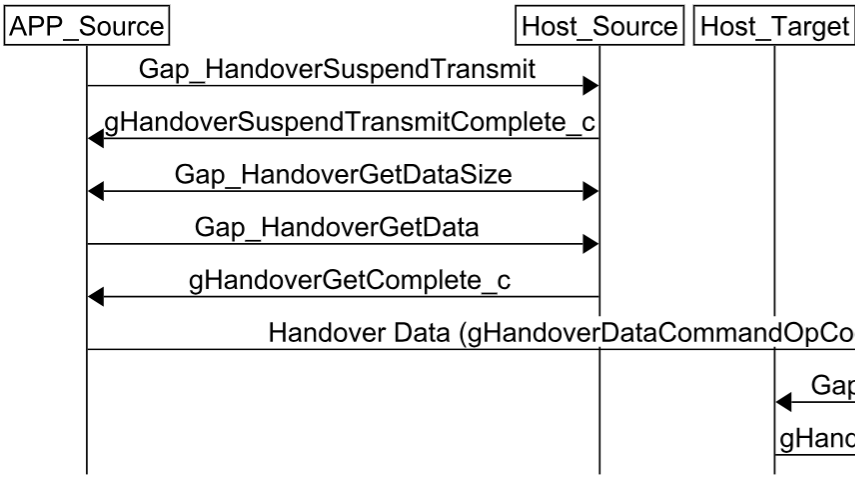
Time synchronization The Time Synchronization procedure enables precise timing alignment between the Source and Target devices for the Connection Handover and Anchor/Packet monitoring processes. The timing information obtained is further required for the Anchor Search procedure.

To start the time synchronization procedure, one of the devices must call GAP_HandoverTimeSyncReceive() and the other device must call GAP_HandoverTimeSyncTransmit(). Either device, Source or Target, can initiate the procedure. The Connection Handover application common module initiates the procedure on the Source device by calling the Gap_HandoverTimeSyncReceive() function.

Time Synchronization steps

Time synchronization steps for two devices where the connected device starts the procedure:

1. Source device application calls GAP_HandoverTimeSyncReceive() with the stopWhenFound parameter set to 'gTimeSyncStopWhenFound_c'.
2. Target device application calls GAP_HandoverTimeSyncTransmit()
3. Source device receives the 'gHandoverTimeSyncReceiveComplete_c' event indicating that Source Link Layer is waiting for the time synchronization event.
4. Target device receives the 'gHandoverTimeSyncTransmitStateChanged_c' event indication that time synchronization transmission is enabled.
5. The Source device receives the 'gHandoverTimeSyncEvent_c' event containing the timing information.
6. The Source device computes the Anchor Search 'timingDiffSlot' and 'timingDiffOffset' using the timing information received in the gHandoverTimeSyncEvent_c event as shown below: 'timingDiffSlot = txClkSlot - rxClkSlot;' 'timingDiffOffset = txUs - rxUs;'



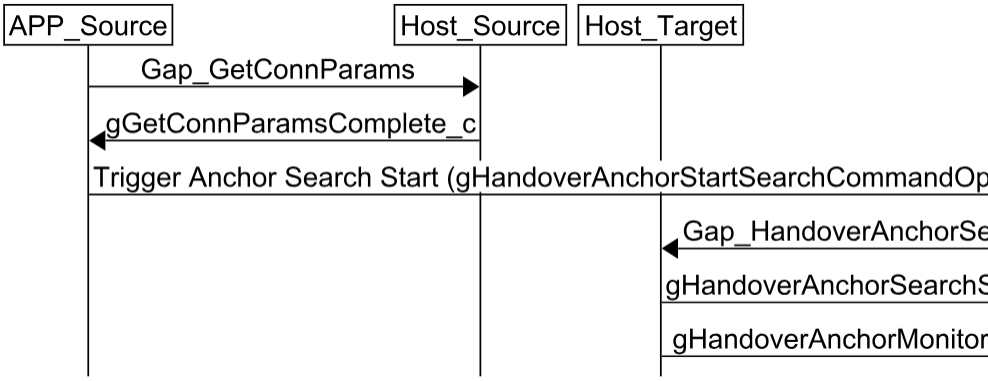
Time Synchronization signaling chart

Context Synchronization In order to transfer an existing connection from a Source device to a Target device, the Host and Link Layer connection context must be synchronized. The Handover Data includes all the required connection information, which must be retrieved from the Source device and transferred to the Target device. Potential issues include instances where the Host or Link Layer context is updated during the Connection Handover process. To avoid such issues, the Bluetooth LE communication between the Source device and the connected device must be suspended until the Connection Handover is complete or aborted. In case the Connection Handover process is aborted, the original connection can be resumed. This procedure is required only for the Connection Handover process and not for the Anchor/Packet Monitoring process.

Context Synchronization steps

1. Source device calls Gap_HandoverSuspendTransmit() to suspend the Bluetooth LE communication with the connected device.
2. After the gHandoverSuspendTransmitComplete_c event is received, the Handover Data may be retrieved using Gap_HandoverGetData(). The application must provided memory for the Handover Data. To obtain the required data size, use the function Gap_HandoverGetDataSize().
3. Wait for the gHandoverGetComplete_c event to confirm the Handover Data retrieval.
4. Transfer the Handover Data from the Source device to the Target device.
5. On the Target device, call Gap_HandoverSetData() to set the received Handover Data.

6. Wait for the gHandoverSetComplete_c event to confirm the Handover Data has been successfully set.



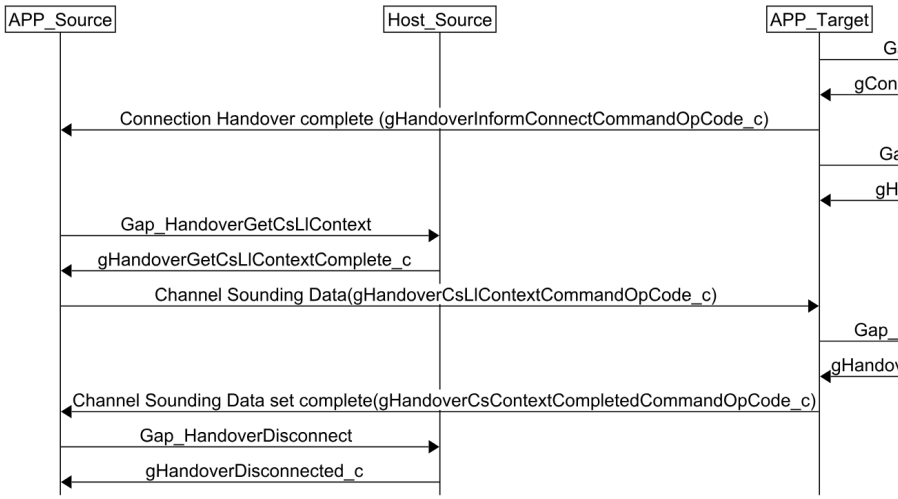
Context Synchronization signaling chart

Anchor Search The Anchor Search procedure takes the connection parameters and timing information obtained in the Time Synchronization procedure to locate the anchor point of the connection between the source device and the connected device.

Anchor Search steps

1. Source device calls Gap_GetConnParams() to retrieve current connection parameters. The connection parameters will be reported through the gGetConnParamsComplete_c event.
2. Send the connection parameters and the timing information obtained from Time Synchronization to the Target device.
3. On the Target device, call Gap_HandoverAnchorSearch() with the received connection parameters and timing information. Set the 'mode' parameter according to the current process:
   - 'gSuspendTxMode_c' for Connection Handover.
   - 'gRssiSniffingMode_c' for Anchor Monitoring.
   - 'gPacketMode_c' for Packet Monitoring.
4. Wait for the gHandoverAnchorSearchStarted_c event to confirm the Anchor Search procedure has started.
5. If Anchor Search is successful the requested events will be reported to the application through the gHandoverAnchorMonitorEvent_c or gHandoverAnchorMonitorPacketEvent_c event.

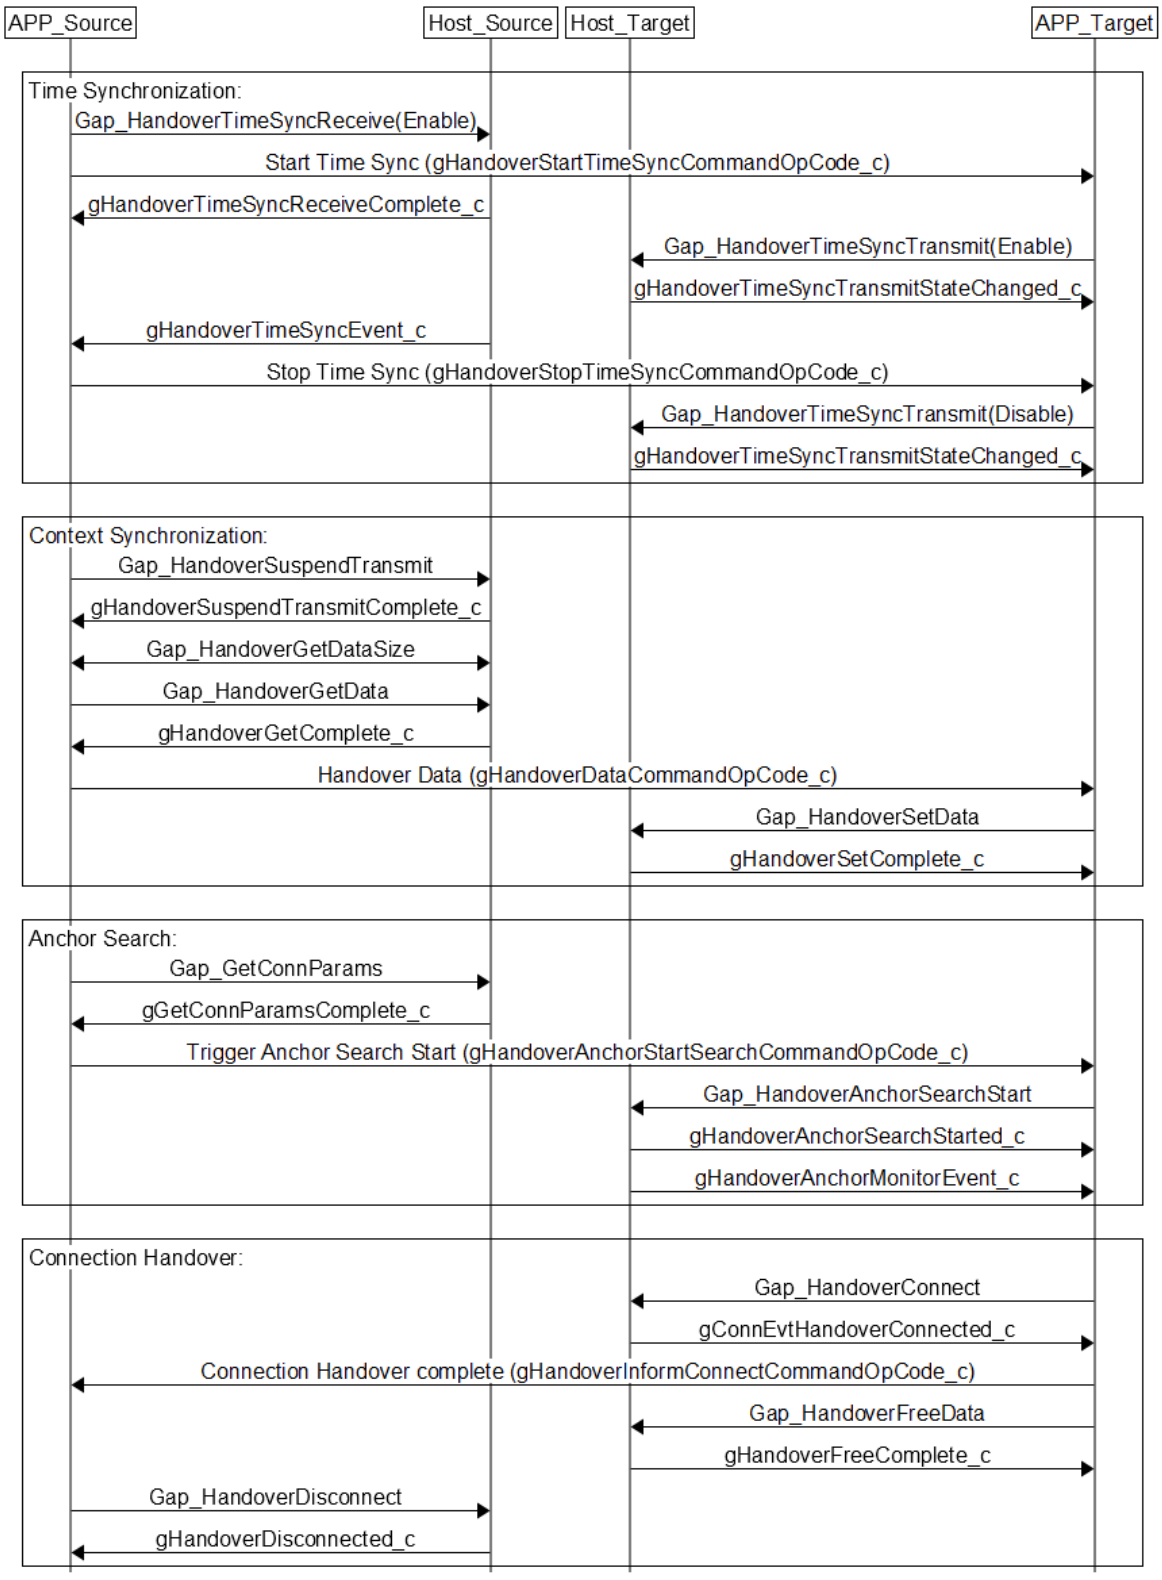
Anchor Search signaling chart



Connection Handover The Connection Handover procedure may be performed after a successful Anchor Search procedure and consists in the Target device taking over the connection from the Source device.

Connection Handover steps

1. Target device calls Gap_HandoverConnect() to initiate the connection handover process.
2. Wait for the gConnEvtHandoverConnected_c event on the Target device. Once received, the connection has been successfully transferred.
3. Notify the Source device that the Target device has successfully connected to the Device.
4. If the application does not include Channel Sounding, call Gap_HandoverDisconnect on the Source device to terminate its connection.
5. The Handover Data is no longer required and may be freed by calling Gap_HandoverFreeData() on the Target device.
6. Application context may be transferred at this point through application specific means. If Channel Sounding is enabled in the application, the Channel Sounding Context must be transferred.



Additional steps for Channel Sounding applications:

1. After step 3 above, retrieve the Channel Sounding context on the Source device by calling Gap_HandoverGetCsLlContext() and wait for thegHandoverGetCsLlContextComplete event.
2. Send the Channel Sounding context to the Target device.
3. Set the context in the Target device by calling Gap_HandoverSetCsLlContext() and wait for the gHandoverSetCsLlContextComplete_c event.
4. Notify the Source device that the Channel Sounding context has been successfully set.
5. Call Gap_HandoverDisconnect() on the Source device to terminate its connection. When complete, the gHandoverDisconnected_c event will be sent.

Anchor/Packet Monitoring

Bluetooth Low Energy Host Stack API Reference Manual

Groups

GAP

enum gapRole_t

GAP Role of a BLE device

Values:

enumerator gGapCentral_c

Central scans and connects to Peripherals.

enumerator gGapPeripheral_c

Peripheral advertises and connects to Centrals.

enumerator gGapObserver_c

Observer only scans and makes no connections.

enumerator gGapBroadcaster_c

Broadcaster only advertises and makes no connections.

enum gapKeypressNotification_tag

Values:

enumerator gKnPasskeyEntryStarted_c

Start of the Passkey Entry.

enumerator gKnPasskeyDigitStarted_c

Digit entered.

enumerator gKnPasskeyDigitErased_c

Digit erased.

enumerator gKnPasskeyCleared_c

Passkey cleared.

enumerator gKnPasskeyEntryCompleted_c

Passkey Entry completed.

enum gapScanMode_t

Scan Mode options; used as parameter for Gap_SetScanMode.

Values:

enumerator gDefaultScan_c

Reports all scanned devices to the application.

enumerator gLimitedDiscovery_c

Reports only devices in Limited Discoverable Mode, i.e., containing the Flags AD with the LE Limited Discoverable Flag set.

enumerator gGeneralDiscovery_c

Reports only devices in General Discoverable Mode, i.e., containing the Flags AD with the LE General Discoverable Flag set.

enumerator gAutoConnect_c

Automatically connects with devices with known addresses and does not report any scanned device to the application.

enum gapAdvertisingChannelMapFlags_t

Advertising Channel Map flags - setting a bit activates advertising on the respective channel.

Values:

enumerator gAdvChanMapFlag37_c

Bit for channel 37.

enumerator gAdvChanMapFlag38_c

Bit for channel 38.

enumerator gAdvChanMapFlag39_c

Bit for channel 39.

enum gapAdvertisingFilterPolicy_t

Advertising Filter Policy values

Values:

enumerator gProcessAll_c

Default value: accept all connect and scan requests.

enumerator gProcessConnAllScanWL_c

Accept all connect requests, but scan requests only from devices in Filter Accept List.

enumerator gProcessScanAllConnWL_c

Accept all scan requests, but connect requests only from devices in Filter Accept List.

enumerator gProcessFilterAcceptListOnly_c

Accept connect and scan requests only from devices in Filter Accept List.

enum gapPeriodicAdvSyncMode_tag

Periodic Advertisement Sync Transfer parameters

Values:

enumerator gapPeriodicSyncNoSyncMode_c

No attempt is made to synchronize to the periodic advertising and no gHciLePeriodicAdvSyncTransferReceived_c event is sent to the Host

enumerator gapPeriodicSyncNoReports_c

A gHciLePeriodicAdvSyncTransferReceived_c event is sent to the Host. gHciLePeriodicAdvReportEvent_c events will be disabled.

enumerator gapPeriodicSyncReportsEnabled_c

A gHciLePeriodicAdvSyncTransferReceived_c event is sent to the Host. gHciLePeriodicAdvReportEvent_c events will be enabled with duplicate filtering disabled

enumerator gapPeriodicSyncReportsEnabledWithDF_c

A gHciLePeriodicAdvSyncTransferReceived_c event is sent to the Host. gHciLePeriodicAdvReportEvent_c events will be enabled with duplicate filtering enabled

enum gapFilterDuplicates_t

Values:

enumerator gGapDuplicateFilteringDisable_c

Duplicate filtering disabled

enumerator gGapDuplicateFilteringEnable_c

Duplicate filtering enabled

enumerator gGapDuplicateFilteringPeriodicEnable_c

Duplicate filtering enabled, reset for each scan period

enum gapCreateSyncReqFilterPolicy_tag

Values:

enumerator gUseCommandParameters_c

Use the SID, peerAddressType, and peerAddress parameters to determine which advertiser to listen to.

enumerator gUsePeriodicAdvList_c

Use the Periodic Advertiser List to determine which advertiser to listen to

enum gapPrivateKeyType_t

Values:

enumerator gUseGeneratedKey_c

The private key generated by LE_Read_Local_P-256_Public_Key command, used for DH key generation

enumerator gUseDebugKey_c

The private debug key, used for DH key generation

enum gapAdType_t

AD Type values as defined by Bluetooth SIG used when defining *gapAdStructure_t* structures for advertising or scan response data.

Values:

enumerator gAdFlags_c

Defined by the Bluetooth SIG.

enumerator gAdIncomplete16bitServiceList_c

Defined by the Bluetooth SIG.

enumerator gAdComplete16bitServiceList_c

Defined by the Bluetooth SIG.

enumerator gAdIncomplete32bitServiceList_c

Defined by the Bluetooth SIG.

enumerator gAdComplete32bitServiceList_c

Defined by the Bluetooth SIG.

enumerator gAdIncomplete128bitServiceList_c

Defined by the Bluetooth SIG.

enumerator gAdComplete128bitServiceList_c

Defined by the Bluetooth SIG.

enumerator gAdShortenedLocalName_c

Defined by the Bluetooth SIG.

enumerator gAdCompleteLocalName_c
Defined by the Bluetooth SIG.

enumerator gAdTxPowerLevel_c
Defined by the Bluetooth SIG.

enumerator gAdClassOfDevice_c
Defined by the Bluetooth SIG.

enumerator gAdSimplePairingHashC192_c
Defined by the Bluetooth SIG.

enumerator gAdSimplePairingRandomizerR192_c
Defined by the Bluetooth SIG.

enumerator gAdSecurityManagerTkValue_c
Defined by the Bluetooth SIG.

enumerator gAdSecurityManagerOobFlags_c
Defined by the Bluetooth SIG.

enumerator gAdPeripheralConnectionIntervalRange_c
Defined by the Bluetooth SIG.

enumerator gAdServiceSolicitationList16bit_c
Defined by the Bluetooth SIG.

enumerator gAdServiceSolicitationList32bit_c
Defined by the Bluetooth SIG.

enumerator gAdServiceSolicitationList128bit_c
Defined by the Bluetooth SIG.

enumerator gAdServiceData16bit_c
Defined by the Bluetooth SIG.

enumerator gAdServiceData32bit_c
Defined by the Bluetooth SIG.

enumerator gAdServiceData128bit_c
Defined by the Bluetooth SIG.

enumerator gAdPublicTargetAddress_c
Defined by the Bluetooth SIG.

enumerator gAdRandomTargetAddress_c
Defined by the Bluetooth SIG.

enumerator gAdAppearance_c
Defined by the Bluetooth SIG.

enumerator gAdAdvertisingInterval_c
Defined by the Bluetooth SIG.

enumerator gAdLeDeviceAddress_c
Defined by the Bluetooth SIG.

enumerator gAdLeRole_c
Defined by the Bluetooth SIG.

enumerator gAdSimplePairingHashC256_c
Defined by the Bluetooth SIG.

enumerator gAdSimplePairingRandomizerR256_c
Defined by the Bluetooth SIG.

enumerator gAd3dInformationData_c
Defined by the Bluetooth SIG.

enumerator gAdUniformResourceIdentifier_c
Defined by the Bluetooth SIG.

enumerator gAdLeSupportedFeatures_c
Defined by the Bluetooth SIG.

enumerator gAdChannelMapUpdateIndication_c
Defined by the Bluetooth SIG.

enumerator gAdAdvertisingIntervalLong_c
Defined by the Bluetooth SIG.

enumerator gAdEncryptedAdvertisingData_c
Defined by the Bluetooth SIG.

enumerator gAdManufacturerSpecificData_c
Defined by the Bluetooth SIG.

enum gapDecisionInstructionsRelevantField_t
Decision Instruction Relevant Field Type.

Values:

enumerator gDIRF_ResolvableTag_c

enumerator gDIRF_AdvMode_c

enumerator gDIRF_RSSI_c

enumerator gDIRF_PathLoss_c

enumerator gDIRF_AdvAddress_c

enumerator gDIRF_ArbitraryDataOfExactly_1Byte_c

enumerator gDIRF_ArbitraryDataOfExactly_2Bytes_c

enumerator gDIRF_ArbitraryDataOfExactly_5Bytes_c

enumerator gDIRF_ArbitraryDataOfExactly_6Bytes_c

enumerator gDIRF_ArbitraryDataOfExactly_7Bytes_c

enumerator gDIRF_ArbitraryDataOfExactly_8Bytes_c

enumerator gDIRF_ArbitraryDataOfAtLeast_1Byte_c

enumerator gDIRF_ArbitraryDataOfAtLeast_2Bytes_c

enumerator gDIRF_ArbitraryDataOfAtLeast_3Bytes_c

enumerator gDIRF_ArbitraryDataOfAtLeast_4Bytes_c

enumerator gDIRF_ArbitraryDataOfAtLeast_5Bytes_c

enumerator gDIRF_ArbitraryDataOfAtLeast_6Bytes_c

enumerator gDIRF_ArbitraryDataOfAtLeast_7Bytes_c

enumerator gDIRF_ArbitraryDataOfAtLeast_8Bytes_c

enumerator gDIRF_ArbitraryDataOfAtMost_1Byte_c

enumerator gDIRF_ArbitraryDataOfAtMost_2Bytes_c

enumerator gDIRF_ArbitraryDataOfAtMost_3Bytes_c

enumerator gDIRF_ArbitraryDataOfAtMost_4Bytes_c

enumerator gDIRF_ArbitraryDataOfAtMost_5Bytes_c

enumerator gDIRF_ArbitraryDataOfAtMost_6Bytes_c

enumerator gDIRF_ArbitraryDataOfAtMost_7Bytes_c

enumerator gDIRF_ArbitraryDataOfAtMost_8Bytes_c

enum gapDecisionInstructionsTestPassCriteria_t

Values:

enumerator gDITPC_Never_c

enumerator gDITPC_CheckPasses_c

enumerator gDITPC_CheckFails_c

enumerator gDITPC_RelevantFieldPresent_c

enumerator gDITPC_RelevantFieldNotPresent_c

enumerator gDITPC_CheckPassesOrRelevantFieldNotPresent_c

enumerator gDITPC_CheckFailsOrRelevantFieldNotPresent_c

enumerator gDITPC_Always_c

enum gapDecisionInstructionsTestGroup_t

Values:

enumerator gDITG_SameTestGroup_c

enumerator gDITG_NewTestGroup_c

enum gapDecisionInstructionsAdvAChecks_t

Values:

enumerator gDIAAC_AdvAinFilterAcceptList_c

enumerator gDIAAC_AdvAmatchAddress1_c

enumerator gDIAAC_AdvAmatchAddress1orAddress2_c

enum gapRadioPowerLevelReadType_t

Enumeration used by the Gap_ReadRadioPowerLevel function.

Values:

enumerator gTxPowerCurrentLevelInConnection_c
Reading the instantaneous TX power level in a connection.

enumerator gTxPowerMaximumLevelInConnection_c
Reading the maximum TX power level achieved during a connection.

enumerator gTxPowerLevelForAdvertising_c
Reading the TX power on the advertising channels.

enumerator gRssi_c
Reading the Received Signal Strength Indication in a connection.

enum gapControllerTestCmd_t
Enumeration for Controller Test commands.
Values:

enumerator gControllerTestCmdStartRx_c
Start Receiver Test.

enumerator gControllerTestCmdStartTx_c
Start Transmitter Test.

enumerator gControllerTestCmdEnd_c
End Test.

enum gapControllerTestTxType_tag
Values:

enumerator gControllerTestTxPrbs9_c
PRBS9 sequence ‘11111111100000111101’...

enumerator gControllerTestTxF0_c
Repeated ‘11110000’

enumerator gControllerTestTxAA_c
Repeated ‘10101010’

enumerator gControllerTestTxPrbs15_c
PRBS15 sequence

enumerator gControllerTestTxFF_c
Repeated ‘11111111’

enumerator gControllerTestTx00_c
Repeated ‘00000000’

enumerator gControllerTestTx0F_c
Repeated ‘00001111’

enumerator gControllerTestTx55_c

Repeated '01010101'

enum gapSleepClockAccuracy_t

Enumeration for Sleep Clock Accuracy command.

Values:

enumerator gSwitchToMoreAccurateClock_c

enumerator gSwitchToLessAccurateClock_c

enum gapAdvertisingEventType_t

Advertising event type enumeration, as contained in the *gapAdvertisingEvent_t*.

Values:

enumerator gAdvertisingStateChanged_c

Event received when advertising has been successfully enabled or disabled.

enumerator gAdvertisingCommandFailed_c

Event received when advertising could not be enabled or disabled. Reason contained in gapAdvertisingEvent_t.eventData.failReason.

enumerator gExtAdvertisingStateChanged_c

Event received when extended advertising has been successfully enabled or disabled.

enumerator gAdvertisingSetTerminated_c

Event received when advertising in a given advertising set has stopped.

enumerator gExtScanNotification_c

Event indicates that a SCAN_REQ PDU or an AUX_SCAN_REQ PDU has been received by the extended advertiser.

enumerator gPerAdvSubeventDataRequest_c

Event received when doing PAWR.

enumerator gPerAdvResponse_c

Periodic Advertising Response.

enum gapScanningEventType_t

Scanning event type enumeration, as contained in the *gapScanningEvent_t*.

Values:

enumerator gScanStateChanged_c

Event received when scanning had been successfully enabled or disabled, or a Scan duration time-out has occurred.

enumerator gScanCommandFailed_c

Event received when scanning could not be enabled or disabled. Reason contained in gapScanningEvent_t.eventData.failReason.

enumerator gDeviceScanned_c

Event received when an advertising device has been scanned. Device data contained in gapScanningEvent_t.eventData.scannedDevice.

enumerator gExtDeviceScanned_c

Event received when an advertising device has been scanned. Device data contained in gapScanningEvent_t.eventData.extScannedDevice.

enumerator gPeriodicDeviceScanned_c

Event received when an Periodic advertising device has been scanned. Device data contained in gapScanningEvent_t.eventData.periodicScannedDevice.

enumerator gPeriodicDeviceScannedV2_c

Event received when an Periodic advertising device has been scanned. Device data contained in gapScanningEvent_t.eventData.periodicScannedDeviceV2.

enumerator gPeriodicAdvSyncEstablished_c

Event received when a sync with a periodic advertiser was established.

enumerator gPeriodicAdvSyncLost_c

Event received when a sync with a periodic advertiser have been lost.

enumerator gPeriodicAdvSyncTerminated_c

Event received when a sync with a periodic advertiser have been terminated.

enumerator gConnectionlessIqReportReceived_c

Event received when the Controller has reported IQ information from the CTE of a received advertising packet

enum gapConnectionEventType_t

Connection event type enumeration, as contained in the *gapConnectionEvent_t*.

Values:

enumerator gConnEvtConnected_c

A connection has been established. Data in gapConnectionEvent_t.eventData.connectedEvent.

enumerator gConnEvtPairingRequest_c

A pairing request has been received from the peer Central. Data in gapConnectionEvent_t.eventData.pairingEvent.

enumerator gConnEvtPeripheralSecurityRequest_c

A Peripheral Security Request has been received from the peer Peripheral. Data in gapConnectionEvent_t.eventData.peripheralSecurityRequestEvent.

enumerator gConnEvtPairingResponse_c

A pairing response has been received from the peer Peripheral. Data in gapConnectionEvent_t.eventData.pairingEvent.

enumerator gConnEvtAuthenticationRejected_c

A link encryption or pairing request has been rejected by the peer device. Data in gapConnectionEvent_t.eventData.authenticationRejectedEvent.

enumerator gConnEvtPasskeyRequest_c

Peer has requested a passkey (maximum 6 digit PIN) for the pairing procedure. Device should respond with Gap_EnterPasskey.

enumerator gConnEvtOobRequest_c

Out-of-Band data must be provided for the pairing procedure. Central or Peripheral should respond with Gap_ProvideOob.

enumerator gConnEvtPasskeyDisplay_c

The pairing procedure requires this Peripheral to display the passkey for the Central's user.

enumerator gConnEvtKeyExchangeRequest_c

The pairing procedure requires the SMP keys to be distributed to the peer. Data in gapConnectionEvent_t.eventData.keyExchangeRequestEvent.

enumerator gConnEvtKeysReceived_c

SMP keys distributed by the peer during pairing have been received. Data in gapConnectionEvent_t.eventData.keysReceivedEvent.

enumerator gConnEvtLongTermKeyRequest_c

The bonded peer Central has requested link encryption and the LTK must be provided. Peripheral should respond with Gap_ProvideLongTermKey. Data in gapConnectionEvent_t.eventData.longTermKeyRequestEvent.

enumerator gConnEvtEncryptionChanged_c

Link's encryption state has changed, e.g., during pairing or after a reconnection with a bonded peer. Data in gapConnectionEvent_t.eventData.encryptionChangedEvent.

enumerator gConnEvtPairingComplete_c

Pairing procedure is complete, either successfully or with failure. Data in gapConnectionEvent_t.eventData.pairingCompleteEvent.

enumerator gConnEvtDisconnected_c

A connection has been terminated. Data in gapConnectionEvent_t.eventData.disconnectedEvent.

enumerator gConnEvtRssiRead_c

RSSI for an active connection has been read. Data in gapConnectionEvent_t.eventData.rssi_dBm.

enumerator gConnEvtTxPowerLevelRead_c

TX power level for an active connection has been read. Data in gapConnectionEvent_t.eventData.txPowerLevel_dBm.

enumerator gConnEvtPowerReadFailure_c

Power reading could not be performed. Data in gapConnectionEvent_t.eventData.failReason.

enumerator gConnEvtParameterUpdateRequest_c

A connection parameter update request has been received. Data in gapConnectionEvent_t.eventData.connectionUpdateRequest.

enumerator gConnEvtParameterUpdateComplete_c

The connection has new parameters. Data in gapConnectionEvent_t.eventData.connectionUpdateComplete.

enumerator gConnEvtLeDataLengthChanged_c

The new TX/RX Data Length parameters. Data in gapConnectionEvent_t.eventData.rssi_dBm.leDataLengthChanged.

enumerator gConnEvtLeScOobDataRequest_c

Event sent to request LE SC OOB Data (r, Cr and Addr) received from a peer.

enumerator gConnEvtLeScDisplayNumericValue_c

Event sent to display and confirm a Numeric Comparison Value when using the LE SC Numeric Comparison pairing method.

enumerator gConnEvtLeScKeypressNotification_c

Remote Keypress Notification received during Passkey Entry Pairing Method.

enumerator gConnEvtChannelMapRead_c

Channel Map was read for a connection. Data is contained in gapConnectionEvent_t.eventData.channelMap

enumerator gConnEvtChannelMapReadFailure_c

Channel Map reading could not be performed. Data in gapConnectionEvent_t.eventData.failReason.

enumerator gConnEvtChanSelectionAlgorithm2_c

LE Channel Selection Algorithm #2 is used on the data channel connection.

enumerator gConnEvtPairingNoLtk_c

No LTK was found for the Central peer. Pairing shall be performed again.

enumerator gConnEvtPairingAlreadyStarted_c

Pairing process was already started

enumerator gConnEvtIqReportReceived_c

Controller has reported IQ information received from a connected peer. Data in gapConnectionEvent_t.eventData.connIqReport.

enumerator gConnEvtCteRequestFailed_c

CTE Request to a connected peer has failed. Data in gapConnectionEvent_t.eventData.cteRequestFailedEvent.

enumerator gConnEvtCteReceiveParamsSetupComplete_c

Connection CTE receive parameters have been successfully set.

enumerator gConnEvtCteTransmitParamsSetupComplete_c

Connection CTE transmit parameters have been successfully set.

enumerator gConnEvtCteReqStateChanged_c

Controller started or stopped initiating the CTE Request procedure.

enumerator gConnEvtCteRspStateChanged_c

Controller enabled or disabled sending CTE Responses for a connection.

enumerator gConnEvtPathLossThreshold_c

Received a Path Loss Threshold event. Data in gapConnectionEvent_t.eventData.pathLossThreshold.

enumerator gConnEvtTransmitPowerReporting_c

Received a Transmit Power report. Data in gapConnectionEvent_t.eventData.transmitPowerReporting.

enumerator gConnEvtEnhancedReadTransmitPowerLevel_c

Local information has been read from Controller. Data in gapConnectionEvent_t.eventData.transmitPowerInfo.

enumerator gConnEvtPathLossReportingParamsSetupComplete_c

Path Loss Reporting parameters have been successfully set.

enumerator gConnEvtPathLossReportingStateChanged_c

Path Loss Reporting has been enabled or disabled.

enumerator gConnEvtTransmitPowerReportingStateChanged_c

Transmit Power Reporting has been enabled or disabled for local and/or remote Controllers.

enumerator gConnEvtEattConnectionRequest_c

Received Enhanced Connection Request for EATT channels.

enumerator gConnEvtEattConnectionComplete_c

Received Enhanced Connection Response for EATT channels.

enumerator gConnEvtEattChannelReconfigureResponse_c

Received Enhanced Channel Reconfigure Response for EATT channels.

enumerator gConnEvtEattBearerStatusNotification_c

Enhanced Bearer status updated

enumerator gConnEvtHandoverConnected_c

A connection has been established through the Handover feature. Data in gapConnectionEvent_t.eventData.handoverConnectedEvent.

enumerator gHandoverDisconnected_c

A connection has been terminated as a result of connection handover.

enumerator gConnEvtLeSetDataLengthFailure_c

The Set Data Length command has failed.

enumerator gConnEvtSmError_c

Security Manager error occured.

enum gapEattBearerStatus_t

Enumeration for Bearer Status Notification command status.

Values:

enumerator gEnhancedBearerActive_c

enumerator gEnhancedBearerSuspendedNoLocalCredits_c

enumerator gEnhancedBearerNoPeerCredits_c

typedef uint8_t gapIoCapabilities_t

I/O Capabilities as defined by the SMP

typedef uint8_t gapSmpKeyFlags_t

Flags indicating the Keys to be exchanged by the SMP during the key exchange phase of pairing.

typedef uint8_t gapSecurityMode_t

LE Security Mode

typedef uint8_t gapSecurityLevel_t

LE Security Level

typedef uint8_t gapSecurityModeAndLevel_t

Security Mode-and-Level definitions

typedef uint8_t gapKeypressNotification_t

Keypress Notification Types

typedef enum *gapKeypressNotification_tag* gapKeypressNotification_tag

typedef uint8_t gapAuthenticationRejectReason_t

Reason for rejecting the pairing request.

typedef struct *gapExtAdvertisingParameters_tag* gapExtAdvertisingParameters_t

Extended Advertising Parameters; for defaults see gGapDefaultExtAdvertisingParameters_d.

typedef struct *gapExtAdvertisingParametersV2_tag* gapExtAdvertisingParametersV2_t

Extended Advertising Parameters V2; for defaults see gGapDefaultExtAdvertisingParametersV2_d.

typedef struct *gapPeriodicAdvParameters_tag* gapPeriodicAdvParameters_t

Periodic Advertising Parameters; for defaults see gGapDefaultPeriodicAdvParameters_d.

typedef struct *gapPeriodicAdvParametersV2_tag* gapPeriodicAdvParametersV2_t
Periodic Advertising Parameters [v2]

typedef enum *gapPeriodicAdvSyncMode_tag* gapPeriodicAdvSyncMode_t
Periodic Advertisement Sync Transfer parameters

typedef struct *gapPeriodicAdvSyncTransfer_tag* gapPeriodicAdvSyncTransfer_t

typedef struct *gapPeriodicAdvSetInfoTransfer_tag* gapPeriodicAdvSetInfoTransfer_t

typedef struct *gapSetPeriodicAdvSyncTransferParams_tag*
gapSetPeriodicAdvSyncTransferParams_t

typedef uint8_t gapCreateSyncReqFilterPolicy_t
Create Sync Request Filter Policy values

typedef struct *gapCreateSyncReqOptions_tag* gapCreateSyncReqOptions_t
Create Sync Request Options

typedef struct *gapPeriodicAdvSyncReq_tag* gapPeriodicAdvSyncReq_t
Periodic Advertising Sync Request parameters

typedef uint8_t gapAdTypeFlags_t
Values of the AD Flags advertising data structure.

typedef uint8_t gapDecisionInstructionsAdvMode_t

typedef struct *gapDecisionInstructionsData_tag* gapDecisionInstructionsData_t

typedef *gapAdvertisingData_t* gapScanResponseData_t
Scan Response Data structure : a list of several *gapAdStructure_t* structures.

typedef uint8_t gapControllerTestTxType_t
Enumeration for Controller Transmitter Test payload types.

typedef *bleResult_t* gapDisconnectionReason_t
Disconnection reason alias - reasons are contained in HCI error codes.

typedef void (*gapAdvertisingCallback_t)(*gapAdvertisingEvent_t* *pAdvertisingEvent)
Advertising Callback prototype.

typedef void (*gapScanningCallback_t)(*gapScanningEvent_t* *pScanningEvent)
Scanning Callback prototype.

typedef void (*gapConnectionCallback_t)(*deviceId_t* deviceId, *gapConnectionEvent_t*
*pConnectionEvent)
Connection Callback prototype.

typedef enum *gapAppearance_tag* gapAppearance_t

Appearance characteristic enumeration, also used in advertising.

typedef struct *gapHostVersion_tag* gapHostVersion_t

bleResult_t Gap_SetDataRelatedAddressChanges(uint8_t advertisingHandle, uint8_t changeReasons)

Command specifies circumstances when the Controller shall refresh any Resolvable Private Address used by the advertising set identified by the Advertising_Handle parameter.

Parameters

- advertisingHandle – **[in]** Identify an advertising set.
- changeReasons – **[in]** Change reasons. Any combination of gAdvDataChange_c and gScanRspDataChange_c. 0U to disable the feature.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range

bleResult_t Gap_RegisterDeviceSecurityRequirements(const *gapDeviceSecurityRequirements_t* *pSecurity)

Registers the device security requirements. This function includes a central security for all services and, optionally, additional stronger security settings for services as required by the profile and/or application.

Remark

pSecurity or any other contained security structure pointers that are NULL are ignored, i.e., defaulted to No Security (Security Mode 1 Level 1, No Authorization, Minimum encryption key size). This function executes synchronously.

Parameters

- pSecurity – **[in]** A pointer to the application-allocated *gapDeviceSecurityRequirements_t* structure.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range

bleResult_t Gap_SetAdvertisingParameters(const *gapAdvertisingParameters_t* *pAdvertisingParameters)

Sets up the Advertising Parameters.

Remark

GAP Peripheral-only API function.

Parameters

- pAdvertisingParameters – **[in]** Pointer to *gapAdvertisingParameters_t* structure.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range
- gBleOutOfMemory_c – Cannot allocate memory for the Host task
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version

bleResult_t Gap_SetAdvertisingData(const *gapAdvertisingData_t* *pAdvertisingData, const *gapScanResponseData_t* *pScanResponseData)

Sets up the Advertising and Scan Response Data.

Remark

Any of the parameters may be NULL, in which case they are ignored. Therefore, this function can be used to set any of the parameters individually or both at once. The standard advertising packet payload is 37 bytes. Some of the payload may be occupied by the Advertiser Address which takes up 6 bytes and for some advertising PDU types also by the Initiator Address which takes another 6 bytes. This leaves 25-31 bytes to the application to include advertising structures (Length [1Byte], AD Type [1 Byte], AD Data[Length-1 Bytes])

Remark

GAP Peripheral-only API function.

Parameters

- pAdvertisingData – **[in]** Pointer to *gapAdvertisingData_t* structure or NULL.
- pScanResponseData – **[in]** Pointer to gapScanResponseData_t structure or NULL.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range
- gGapAdvDataTooLong_c – The advertising data length is too big
- gBleOutOfMemory_c – Cannot allocate memory for the Host task
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version

bleResult_t Gap_StartAdvertising(*gapAdvertisingCallback_t* advertisingCallback, *gapConnectionCallback_t* connectionCallback)

Commands the controller to start advertising.

Remark

The advertisingCallback confirms or denies whether the advertising has started. The connectionCallback is only used if a connection gets established during advertising.

Remark

GAP Peripheral-only API function.

Parameters

- advertisingCallback – **[in]** Callback used by the application to receive advertising events. Can be NULL.
- connectionCallback – **[in]** Callback used by the application to receive connection events. Can be NULL.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleInvalidState_c – Advertising is already started or pending to be started
- gBleOutOfMemory_c – Cannot allocate memory for the Host task
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version

bleResult_t Gap_StopAdvertising(void)

Commands the controller to stop advertising.

Remark

GAP Peripheral-only API function.

Return values

- gBleSuccess_c –
- gBleInvalidState_c – Advertising is already stopped or pending to be stopped
- gBleOutOfMemory_c – Cannot allocate memory for the Host task
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version

bleResult_t Gap_Authorize(*deviceId_t* deviceId, uint16_t handle, *gattDbAccessType_t* access)

Authorizes a peer for an attribute in the database.

Remark

This function executes synchronously.

Remark

GATT Server-only API function.

Parameters

- deviceId – **[in]** The peer being authorized.
- handle – **[in]** The attribute handle.
- access – **[in]** The type of access granted (gAccessRead_c or gAccessWrite_c).

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range
- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory
- gBleInvalidParameter_c – The deviceId parameter is not valid or the access parameter is not gAccessRead_c or gAccessWrite_c
- gBleUnexpectedError_c – Saving to NVM failed (module not initialized or corrupted NVM)
- gBleOverflow_c – the number of handles to be read or written from the NVM is bigger than gcGapMaxAuthorizationHandles_c
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version

bleResult_t Gap_SaveCccd(*deviceId_t* deviceId, uint16_t handle, *gattCccdFlags_t* cccd)

Save the CCCD value for a specific Client and CCCD handle.

Remark

The GATT Server layer saves the CCCD value automatically when it is written by the Client. This API should only be used to save the CCCD in other situations, e.g., when for some reason the application decides to disable notifications/indications for a specific Client.

Remark

This function executes synchronously.

Remark

GATT Server-only API function.

Parameters

- deviceId – **[in]** The peer GATT Client.
- handle – **[in]** The handle of the CCCD as defined in the GATT Database.
- cccd – **[in]** The bit mask representing the CCCD value to be saved.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range
- gBleUnexpectedError_c – Saving to NVM failed (module not initialized or corrupted NVM)
- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory
- gDevDbCccdLimitReached_c – No more room in NVM

bleResult_t Gap_CheckNotificationStatus(*deviceId_t* deviceId, uint16_t handle, bool_t *pOutIsActive)

Retrieves the notification status for a given Client and a given CCCD handle.

Remark

This function executes synchronously.

Remark

GATT Server-only API function.

Parameters

- deviceId – **[in]** The peer GATT Client.
- handle – **[in]** The handle of the CCCD.
- pOutIsActive – **[out]** The address to store the status into.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range
- gDevDbCccdNotFound_c – The handle is not CCCD
- gBleUnavailable_c – The bond data entry for this device is corrupted

bleResult_t Gap_CheckIndicationStatus(*deviceId_t* deviceId, uint16_t handle, bool_t *pOutIsActive)

Retrieves the indication status for a given Client and a given CCCD handle.

Remark

This function executes synchronously.

Remark

GATT Server-only API function.

Parameters

- deviceId – **[in]** The peer GATT Client.
- handle – **[in]** The handle of the CCCD.
- pOutIsActive – **[out]** The address to store the status into.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gDevDbCccdNotFound_c – The handle is not CCCD.
- gBleUnavailable_c – The bond data entry for this device is corrupted.

bleResult_t Gap_GetBondedDevicesIdentityInformation(*gapIdentityInformation_t* *aOutIdentityAddresses, uint8_t maxDevices, uint8_t *pOutActualCount)

Retrieves a list of the identity information of bonded devices, if any.

Remark

This API may be useful when creating a filter accept list or a resolving list.

Remark

This function executes synchronously.

Parameters

- aOutIdentityAddresses – **[out]** Array of identities to be filled.
- maxDevices – **[in]** Maximum number of identities to be obtained.
- pOutActualCount – **[out]** The actual number of identities written.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleInvalidParameter_c – A parameter has an invalid value, is outside the accepted range, or the NVM entry is invalid

bleResult_t Gap_Pair(*deviceId_t* deviceId, const *gapPairingParameters_t* *pPairingParameters)

Initiates pairing with a peer device.

Remark

GAP Central-only API function.

Parameters

- deviceId – **[in]** The peer to pair with.
- pPairingParameters – **[in]** Pairing parameters as required by the SMP.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range
- gBleOutOfMemory_c – Cannot allocate memory for the Host task

bleResult_t Gap_SendPeripheralSecurityRequest(*deviceId_t* deviceId, const *gapPairingParameters_t* *pPairingParameters)

Informs the peer Central about the local security requirements.

Remark

The procedure has the same parameters as the pairing request, but, because it is initiated by the Peripheral, it has no pairing effect. It only informs the Central about the requirements.

Remark

GAP Peripheral-only API function.

Parameters

- deviceId – **[in]** The GAP peer to pair with.
- pPairingParameters – **[in]** Pairing parameters as required by the SMP.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleOutOfMemory_c – Cannot allocate memory for the Host task

bleResult_t Gap_EncryptLink(*deviceId_t* deviceId)

Encrypts the link with a bonded peer.

Remark

GAP Central-only API function.

Parameters

- deviceId – **[in]** Device ID of the peer.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gGapDeviceNotBonded_c – Trying to execute an API that is only available for bonded devices.

bleResult_t Gap_AcceptPairingRequest(*deviceId_t* deviceId, const *gapPairingParameters_t* *pPairingParameters)

Accepts the pairing request from a peer.

Remark

This should be called in response to a gPairingRequest_c event.

Remark

GAP Peripheral-only API function.

Parameters

- deviceId – **[in]** The peer requesting authentication.
- pPairingParameters – **[in]** Pairing parameters as required by the SMP.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_RejectPairing(*deviceId_t* deviceId, *gapAuthenticationRejectReason_t* reason)

Rejects the peer's authentication request.

Parameters

- deviceId – **[in]** The GAP peer who requested authentication.
- reason – **[in]** Reason why the current device rejects the authentication.

Return values

- gBleSuccess_c –

- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_EnterPasskey(*deviceId_t* deviceId, uint32_t passkey)

Enters the passkey requested by the peer during the pairing process.

Parameters

- deviceId – **[in]** The GAP peer that requested a passkey entry.
- passkey – **[in]** The peer's secret passkey.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_ProvideOob(*deviceId_t* deviceId, const uint8_t *aOob)

Provides the Out-Of-Band data for the SMP Pairing process.

Parameters

- deviceId – **[in]** The pairing device.
- aOob – **[in]** Pointer to OOB data (array of gcSmpOobSize_d size).

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_RejectPasskeyRequest(*deviceId_t* deviceId)

Rejects the passkey request from a peer.

Remark

GAP Central-only API function.

Parameters

- deviceId – **[in]** The GAP peer that requested a passkey entry.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SendSmpKeys(*deviceId_t* deviceId, const *gapSmpKeys_t* *pKeys)

Sends the SMP keys during the SMP Key Exchange procedure.

Parameters

- deviceId – **[in]** The GAP peer who initiated the procedure.
- pKeys – **[in]** The SMP keys of the local device.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_RejectKeyExchangeRequest(*deviceId_t* deviceId)

Rejects the Key Exchange procedure with a paired peer.

Parameters

- deviceId – **[in]** The GAP peer who requested the Key Exchange procedure.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeScRegeneratePublicKey(void)

Regenerates the private/public key pair used for LE Secure Connections pairing.

Remark

The application should listen for the gLeScPublicKeyRegenerated_c generic event.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeScValidateNumericValue(*deviceId_t* deviceId, bool_t valid)

Validates the numeric value during the Numeric Comparison LE Secure Connections pairing.

Parameters

- deviceId – **[in]** Device ID of the peer.
- valid – **[in]** TRUE if user has indicated that numeric values are matched, FALSE otherwise.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeScGetLocalOobData(void)

Retrieves local OOB data used for LE Secure Connections pairing.

Remark

The application should listen for the gLeScLocalOobData_c generic event.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeScSetPeerOobData(*deviceId_t* deviceId, const *gapLeScOobData_t* *pPeerOobData)

Sets peer OOB data used for LE Secure Connections pairing.

Remark

This function should be called in response to the gConnEvtLeScOobDataRequest_c event.

Parameters

- deviceId – **[in]** Device ID of the peer.
- pPeerOobData – **[in]** OOB data received from the peer.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_LeScSendKeypressNotification(*deviceId_t* deviceId, *gapKeypressNotification_t* keypressNotification)

Sends a Keypress Notification to the peer.

Remark

This function shall only be called during the passkey entry process and only if both peers support Keypress Notifications.

Parameters

- deviceId – **[in]** Device ID of the peer.
- keypressNotification – **[in]** Value of the Keypress Notification.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_ProvideLongTermKey(*deviceId_t* deviceId, const uint8_t *aLtk, uint8_t ltkSize)

Provides the Long Term Key (LTK) to the controller for encryption setup.

Remark

The application should provide the same LTK used during bonding with the respective peer.

Remark

GAP Peripheral-only API function.

Parameters

- deviceId – **[in]** The GAP peer who requested encryption.
- aLtk – **[in]** The Long Term Key.
- ltkSize – **[in]** The Long Term Key size.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_DenyLongTermKey(*deviceId_t* deviceId)

Rejects an LTK request originating from the controller.

Remark

GAP Peripheral-only API function.

Parameters

- deviceId – **[in]** The GAP peer who requested encryption.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LoadEncryptionInformation(*deviceId_t* deviceId, uint8_t *aOutLtk, uint8_t *pOutLtkSize)

Loads the encryption key for a bonded device.

Remark

This function executes synchronously.

Parameters

- deviceId – **[in]** Device ID of the peer.
- aOutLtk – **[out]** Array of size gcMaxLtkSize_d to be filled with the LTK.
- pOutLtkSize – **[out]** The LTK size.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleUnavailable_c – The bond data entry for this device is corrupted.

bleResult_t Gap_SetLocalPasskey(uint32_t passkey)

Sets the SMP passkey for this device.

Remark

This is the PIN that the peer's user must enter during pairing.

Remark

This function executes synchronously.

Remark

GAP Peripheral-only API function.

Parameters

- passkey – **[in]** The SMP passkey.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gSmInvalidDeviceId_c – The device ID is not valid or it has been disconnected in the meantime.
- gSmInvalidCommandCode_c – An invalid internal state machine code was requested.
- gSmPairingAlreadyStarted_c – Pairing process was already started.
- gSmInvalidInternalOperation_c – A memory corruption or invalid operation may have occurred.
- gSmSmpTimeoutOccurred_c – An SMP timeout has occurred for the peer device.

- gSmInvalidCommandParameter_c – One of the parameters of the SM command is not valid.
- gSmCommandNotSupported_c – The Security Manager does not have the required features or version to support this command
- gSmUnexpectedCommand_c – This command is not or cannot be handled in the current context of the SM.
- gSmSmpPacketReceivedAfterTimeoutOccurred_c – A SMP packet has been received from a peer device for which a pairing procedure has timed out.
- gSmUnexpectedPairingTerminationReason_c – The upper layer tried to cancel the pairing procedure with an unexpected pairing failure reason for the current phase of the pairing procedure.

bleResult_t Gap_SetScanMode(*gapScanMode_t* scanMode, *gapAutoConnectParams_t* *pAutoConnectParams, *gapConnectionCallback_t* connCallback)

Sets internal scan filters and actions.

Remark

This function can be called before Gap_StartScanning. If this function is never called, then the default value of gDefaultScan_c is considered and all scanned devices are reported to the application without any additional filtering or action.

Remark

This function executes synchronously.

Remark

GAP Central-only API function.

Parameters

- scanMode – **[in]** The scan mode to be activated. Default is gDefaultScan_c.
- pAutoConnectParams – **[in]** Pointer to the *gapAutoConnectParams_t* structures if scanMode is set to gAutoConnect_c. The memory used must be persistent and should not change during the next scan periods or until another Gap_SetScanMode is called.
- connCallback – **[in]** Auto-Connect callback. Must be set if scanMode is set to gAutoConnect_c.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_SetDecisionInstructions(uint8_t numTest, const *gapDecisionInstructionsData_t* *pDecisionInstructions)

Sets up the Decision Instructions.

Remark

GAP Central-only API function.

Remark

Application should wait for gDecisionInstructionsSetupComplete_c generic event or for gInternalError_c generic event with errorSource = gSetDecisionInstructions_c.

Parameters

- numTest – **[in]** The number of tests in the decision instructions.
- pDecisionInstructions – **[in]** Pointer to an array of gapDecisionInstructionsData_t structures. containing decision instruction for each test.

Return values

- gBleFeatureNotSupported_c – in case gLeExtendedAdv_c or gLeDecisionBasedAdvertisingFiltering_c are not supported.
- gBleInvalidParameter_c – in case at least 1 parameter is incorrect.
- gBleOutOfMemory_c – in case the memory allocation for the app to host message fails.
- gBleSuccess_c – otherwise.

bleResult_t Gap_StartScanning(const *gapScanningParameters_t* *pScanningParameters, *gapScanningCallback_t* scanningCallback, *gapFilterDuplicates_t* enableFilterDuplicates, uint16_t duration, uint16_t period)

Optionally sets the scanning parameters and begins scanning.

Remark

Use this API to both set the scanning parameters and start scanning. If pScanningParameters is NULL, scanning is started with the existing settings.

Remark

GAP Central-only API function.

Parameters

- pScanningParameters – **[in]** The scanning parameters; may be NULL.
- scanningCallback – **[in]** The scanning callback.
- enableFilterDuplicates – **[in]** Enable or disable duplicate advertising report filtering

- duration – **[in]** Scan duration expressed in units of 10 ms. Set 0 for continuous scan until explicitly disabled. Used only for BLE5.0, otherwise ignored.
- period – **[in]** Time interval expressed in units of 1.28 seconds from when the Controller started its last Scan_Duration until it begins the subsequent Scan_Duration. Set 0 to disable periodic scanning. Used only for BLE5.0, otherwise ignored.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidState_c – The requested API cannot be called in the current state, scanning was already started.

bleResult_t Gap_StopScanning(void)

Commands the controller to stop scanning.

Remark

GAP Central-only API function.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidState_c – The requested API cannot be called in the current state, scanning is in the process of stopping.

bleResult_t Gap_Connect(const *gapConnectionRequestParameters_t* *pParameters,
gapConnectionCallback_t connCallback)

Connects to a scanned device.

Remark

GAP Central-only API function.

Parameters

- pParameters – **[in]** Create Connection command parameters.
- connCallback – **[in]** Callback used to receive connection events.

Return values

- gBleSuccess_c –

- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_ConnectFromPawr(const *gapConnectionFromPawrParameters_t* *pParameters, *gapConnectionCallback_t* connCallback)

Connects to a device which is doing periodic advertising with responses.

Remark

GAP Central-only API function.

Parameters

- pParameters – **[in]** Create Connection command parameters.
- connCallback – **[in]** Callback used to receive connection events.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_Disconnect(*deviceId_t* deviceId)

Initiates disconnection from a connected peer device.

Parameters

- deviceId – **[in]** The connected peer to disconnect from.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SaveCustomPeerInformation(*deviceId_t* deviceId, const uint8_t *pInfo, uint16_t offset, uint16_t infoSize)

Saves custom peer information in raw data format.

Remark

This function can be called by the application to save custom information about the peer device, e.g., Service Discovery data (to avoid doing it again on reconnection).

Remark

This function executes synchronously.

Parameters

- deviceId – **[in]** Device ID of the GAP peer.
- pInfo – **[in]** Pointer to the beginning of the data.
- offset – **[in]** Offset from the beginning of the reserved memory area.
- infoSize – **[in]** Data size (maximum equal to gcReservedFlashSizeForCustomInformation_d).

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory.

bleResult_t Gap_LoadCustomPeerInformation(*deviceId_t* deviceId, uint8_t *pOutInfo, uint16_t offset, uint16_t infoSize)

Loads the custom peer information in raw data format.

Remark

This function can be called by the application to load custom information about the peer device, e.g., Service Discovery data (to avoid doing it again on reconnection).

Remark

This function executes synchronously.

Parameters

- deviceId – **[in]** Device ID of the GAP peer.
- pOutInfo – **[out]** Pointer to the beginning of the allocated memory.
- offset – **[in]** Offset from the beginning of the reserved memory area.
- infoSize – **[in]** Data size (maximum equal to gcReservedFlashSizeForCustomInformation_d).

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleUnavailable_c – The bond data entry for this device is corrupted.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory.

bleResult_t Gap_CheckIfBonded(*deviceId_t* deviceId, bool_t *pOutIsBonded, uint8_t *pOutNvmIndex)

Returns whether or not a connected peer device is bonded and the NVM index.

Remark

This function executes synchronously.

Parameters

- deviceId – **[in]** Device ID of the GAP peer.
- pOutIsBonded – **[out]** Boolean to be filled with the bonded flag.
- pOutNvmIndex – **[out]** If bonded, to be filled optionally with the NVM index.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_CheckIfConnected(*bleAddressType_t* addressType, const *bleDeviceAddress_t* aAddress, bool_t addrResolved, bool_t *pOutIsConnected)

Checks if a connection exists between the local device and another device that has the provided address information. This function executes synchronously.

Parameters

- addressType – **[in]** Peer address type
- aAddress – **[in]** Peer address
- addrResolved – **[in]** Set to TRUE if the address contained in the addressType and aAddress fields is the identity address of a resolved RPA.
- pOutIsConnected – **[out]** TRUE if the device is found

Return values

- bleResult_t –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_CheckNvmIndex(uint8_t nvmIndex, bool_t *pOutIsFree)

Returns whether or not the given NVM index is free.

Remark

This function executes synchronously.

Parameters

- nvmIndex – **[in]** NVM index.
- pOutIsFree – **[out]** TRUE if free, FALSE if occupied.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_ReadFilterAcceptListSize(void)

Retrieves the size of the Filter Accept List.

Remark

Response is received in the gFilterAcceptListSizeRead_c generic event.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_ClearFilterAcceptList(void)

Removes all addresses from the Filter Accept List, if any.

Remark

Confirmation is received in the gFilterAcceptListCleared_c generic event.

Return values

gBleSuccess_c –

bleResult_t Gap_AddDeviceToFilterAcceptList(*bleAddressType_t* addressType, const *bleDeviceAddress_t* address)

Adds a device address to the Filter Accept List.

Parameters

- address – **[in]** The address of the filter accept listed device.
- addressType – **[in]** The device address type (public or random).

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_RemoveDeviceFromFilterAcceptList(*bleAddressType_t* addressType, const *bleDeviceAddress_t* address)

Removes a device address from the Filter Accept List.

Parameters

- address – **[in]** The address of the filter accept listed device.
- addressType – **[in]** The device address type (public or random).

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_ReadPublicDeviceAddress(void)

Reads the device's public address from the controller.

Remark

The application should listen for the gPublicAddressRead_c generic event.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_CreateRandomDeviceAddress(const uint8_t *aIrk, const uint8_t *aRandomPart)

Requests the controller to create a random address.

Remark

The application should listen for the gRandomAddressReady_c generic event. Note that this does not set the random address in the Controller. To set the random address, call *Gap_SetRandomAddress()* with the generated address contained in the event data.

Parameters

- aIrk – **[in]** The Identity Resolving Key to be used for a private resolvable address or NULL for a private non-resolvable address (fully random).
- aRandomPart – **[in]** If aIrk is not NULL, this is a 3-byte array containing the Random Part of a Private Resolvable Address, in LSB to MSB order; the most significant two bits of the most significant byte (aRandomPart[3] & 0xC0) are ignored. This may be NULL, in which case the Random Part is randomly generated internally.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SaveDeviceName(*deviceId_t* deviceId, const uchar_t *pName, uint8_t cNameSize)

Store the name of a bonded device.

Remark

This function copies cNameSize characters from the pName array and adds the NULL character to terminate the string.

Remark

This function executes synchronously.

Parameters

- deviceId – **[in]** Device ID for the active peer which name is saved.
- pName – **[in]** Array of characters holding the name.
- cNameSize – **[in]** Number of characters to be saved.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory.

bleResult_t Gap_GetBondedDevicesCount(uint8_t *pOutBondedDevicesCount)

Retrieves the number of bonded devices.

Remark

This function executes synchronously.

Parameters

- pOutBondedDevicesCount – **[out]** Pointer to integer to be written.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_GetBondedDeviceName(uint8_t nvmIndex, uchar_t *pOutName, uint8_t maxNameSize)

Retrieves the name of a bonded device.

Remark

nvmIndex is an integer ranging from 0 to N-1, where N is the number of bonded devices and can be obtained by calling Gap_GetBondedDevicesCount(&N).

Remark

This function executes synchronously.

Parameters

- nvmIndex – **[in]** Index of the device in NVM bonding area.
- pOutName – **[out]** Destination array to copy the name into.
- maxNameSize – **[in]** Maximum number of characters to be copied, including the terminating NULL character.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleUnavailable_c – The bond data entry for this device is corrupted.

bleResult_t Gap_SetBondedDeviceName(uint8_t nvmIndex, const uchar_t *pName, uint8_t cNameSize)

Store the name of a bonded device.

Remark

This function copies cNameSize characters from the pName array and adds the NULL character to terminate the string.

Remark

This function executes synchronously.

Parameters

- nvmIndex – **[in]** Index of the device in NVM bonding area.
- pName – **[in]** Array of characters holding the name.
- cNameSize – **[in]** Number of characters to be saved.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory.

bleResult_t Gap_RemoveBond(uint8_t nvmIndex)

Removes the bond with a device.

Remark

This API requires that there are no active connections at call time. The *Gap_CheckIfBonded()* API can be called to obtain the nvmIndex of a bonded peer.

Remark

This function executes synchronously.

Parameters

- nvmIndex – **[in]** Index of the device in the NVM bonding area.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleUnavailable_c – The bond data entry for this device is corrupted.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleInvalidState_c – The bond is not active.

bleResult_t Gap_RemoveAllBonds(void)

Removes all bonds with other devices.

Remark

This API requires that there are no active connections at call time.

Remark

This function executes synchronously.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleInvalidState_c – At least one bond is still active.

bleResult_t Gap_ReadRadioPowerLevel(*gapRadioPowerLevelReadType_t* txReadType, *deviceId_t* deviceId)

Reads the power level of the controller's radio. The response is contained in the gConnEvtTxPowerLevelRead_c connection event when reading connection TX power level, the

gAdvTxPowerLevelRead_c generic event when reading the advertising TX power level, or the gConnEvtRssiRead_c connection event when reading the RSSI.

Parameters

- txReadType – **[in]** Advertising or connection Tx power
- deviceId – **[in]** Peer identifier (for connections only, otherwise ignored)

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetTxPowerLevel(uint8_t powerLevel, *bleTransmitPowerChannelType_t* channelType)

Sets the Tx power level on the controller's radio.

Remark

The application should listen for the gTxPowerLevelSetComplete_c generic event.

Remark

This function executes synchronously.

Remark

For QN908x platform this command is not supported by the controller.

Remark

Instead, use RF_SetTxPowerLevel API to set the desired TX power level.

Parameters

- powerLevel – **[in]** Power level as specified in the controller interface.
- channelType – **[in]** The advertising or connection channel type.

Return values

gBleSuccess_c –

bleResult_t Gap_VerifyPrivateResolvableAddress(uint8_t nvmIndex, const *bleDeviceAddress_t* aAddress)

Verifies a Private Resolvable Address with a bonded device's IRK.

Remark

nvmIndex is an integer ranging from 0 to N-1, where N is the number of bonded devices and can be obtained by calling Gap_GetBondedDevicesCount(&N); the application should listen to the gPrivateResolvableAddressVerified_c event.

Parameters

- nvmIndex – **[in]** Index of the device in NVM bonding area whose IRK must be checked.
- aAddress – **[in]** The Private Resolvable Address to be verified.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetRandomAddress(const *bleDeviceAddress_t* aAddress)

Sets a random address into the Controller.

Remark

The application should listen for the gRandomAddressSet_c generic event.

Parameters

- aAddress – **[in]** The Private Resolvable, Private Non-Resolvable, or Static Random Address.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_ReadControllerLocalRPA(const *bleIdentityAddress_t* *pIdAddress)

Reads the device's Local Private Address for a specific peer device from the controller.

Remark

The application should listen for the gControllerLocalRPARead_c generic event.

Parameters

- pIdAddress – **[in]** pointer to the peer identity address the local private address should be retrieved for.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidState_c – The Controller privacy is not enabled.

bleResult_t Gap_SetDefaultPairingParameters(const *gapPairingParameters_t* *pPairingParameters)

Sets the default pairing parameters to be used by automatic pairing procedures.

Remark

When these parameters are set, the Security Manager automatically responds to a Pairing Request or a Peripheral Security Request using these parameters. If NULL is provided, it returns to the default state where all security requests are sent to the application.

Remark

This function executes synchronously.

Parameters

- pPairingParameters – **[in]** Pairing parameters as required by the SMP or NULL.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_UpdateConnectionParameters(*deviceId_t* deviceId, uint16_t intervalMin, uint16_t intervalMax, uint16_t peripheralLatency, uint16_t timeoutMultiplier, uint16_t minCeLength, uint16_t maxCeLength)

Request a set of new connection parameters.

Parameters

- deviceId – **[in]** The DeviceID for which the command is intended
- intervalMin – **[in]** The minimum value for the connection event interval
- intervalMax – **[in]** The maximum value for the connection event interval
- peripheralLatency – **[in]** The peripheral latency parameter
- timeoutMultiplier – **[in]** The connection timeout parameter
- minCeLength – **[in]** The minimum value for the connection event length
- maxCeLength – **[in]** The maximum value for the connection event length

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

Pre

A connection must be in place

bleResult_t Gap_EnableUpdateConnectionParameters(*deviceId_t* deviceId, bool_t enable)

Update the connection parameters.

Remark

The LE central Host may accept the requested parameters or reject the request

Parameters

- deviceId – **[in]** The DeviceID for which the command is intended
- enable – **[in]** Allow/disallow the parameters update

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – The device id is not valid.

Pre

A connection must be in place

bleResult_t Gap_UpdateLeDataLength(*deviceId_t* deviceId, uint16_t txOctets, uint16_t txTime)

Update the Tx Data Length.

Remark

The response is contained in the gConnEvtLeDataLengthUpdated_c connection event.

Parameters

- deviceId – **[in]** The DeviceID for which the command is intended
- txOctets – **[in]** Maximum transmission number of payload octets
- txTime – **[in]** Maximum transmission time

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – The device id is not valid.

Pre

A connection must be in place

bleResult_t Gap_EnableHostPrivacy(bool_t enable, const uint8_t *aIrk)

Enables or disables Host Privacy (automatic regeneration of a Private Address).

Remark

The application should listen for the gHostPrivacyStateChanged_c generic event.

Parameters

- enable – **[in]** TRUE to enable, FALSE to disable.
- aIrk – **[in]** Local IRK to be used for Resolvable Private Address generation or NULL for Non-Resolvable Private Address generation. Ignored if enable is FALSE.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnableControllerPrivacy(bool_t enable, const uint8_t *aOwnIrk, uint8_t peerIdCount, const *gapIdentityInformation_t* *aPeerIdentities)

Enables or disables Controller Privacy (Enhanced Privacy feature).

Remark

The application should listen for the gControllerPrivacyStateChanged_c generic event.

Parameters

- enable – **[in]** TRUE to enable, FALSE to disable.
- aOwnIrk – **[in]** Local IRK. Ignored if enable is FALSE, otherwise shall not be NULL.
- peerIdCount – **[in]** Size of aPeerIdentities array. Shall not be zero or greater than gcGapControllerResolvingListSize_c. Ignored if enable is FALSE.
- aPeerIdentities – **[in]** Array of peer identity addresses and IRKs. Ignored if enable is FALSE, otherwise shall not be NULL.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleFeatureNotSupported_c – Cannot use Device Privacy mode if controller does not support LE Set Privacy Mode Command.

bleResult_t Gap_SetPrivacyMode(uint8_t nvmIndex, *blePrivacyMode_t* privacyMode)

Sets the privacy mode to an existing bond.

Remark

The change has no effect (other than the change in NVM) unless controller privacy is enabled for the bonded identities.

Parameters

- nvmIndex – **[in]** Index of the device in the NVM bonding area.
- privacyMode – **[in]** Controller privacy mode: Network or Device

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Cannot use Device Privacy mode if controller does not support LE Set Privacy Mode Command.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleUnavailable_c – The bond data entry for this device is corrupted.
- gBleOutOfMemory_c – There is no more room to allocate memory for a bonding entry.

bleResult_t Gap_ControllerTest(*gapControllerTestCmd_t* testCmd, uint8_t radioChannel, uint8_t txDataLength, *gapControllerTestTxType_t* txPayloadType)

Commands a Controller Test procedure.

Remark

The application should listen for the gControllerTestEvent_c generic event.

Remark

This API function is available only in the full-featured host library.

Parameters

- testCmd – Command type - “start TX test”, “start RX test” or “end test”.
- radioChannel – Radio channel index. Valid range: 0-39. Frequency will be F[MHz] = 2402 + 2 * index. Effective range: 2402-2480 MHz. Ignored if command is “end test”.
- txDataLength – Size of packet payload for TX tests. Ignored if command is “start RX test” or “end test”.
- txPayloadType – Type of packet payload for TX tests. Ignored if command is “start RX test” or “end test”.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_ModifySleepClockAccuracy(*gapSleepClockAccuracy_t* action)

Requests the Controller to change its sleep clock accuracy for testing purposes.

Remark

The application should listen for the generic event.

Parameters

- action – Specifies whether the sleep clock should be changed to one that is more accurate or one that is less accurate.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_LeReadPhy(*deviceId_t* deviceId)

Read the Tx and Rx Phy on the connection with a device.

Remark

The application should listen for the gLePhyEvent_c generic event. This API is available only in the Bluetooth 5.0 Host Stack.

Parameters

- deviceId – **[in]** Device ID of the peer.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeSetPhy(bool_t defaultMode, *deviceId_t* deviceId, uint8_t allPhys, uint8_t txPhys, uint8_t rxPhys, uint16_t phyOptions)

Set the Tx and Rx Phy preferences on the connection with a device or all subsequent connections.

Remark

The application should listen for the gLePhyEvent_c generic event. This API is available only in the Bluetooth 5.0 Host Stack.

Parameters

- defaultMode – **[in]** Use the provided values for all subsequent connections
- deviceId – **[in]** Device ID of the peer Ignored if defaultMode is TRUE.
- allPhys – **[in]** Host preferences on Tx and Rx Phy, as defined by gapLeAllPhyFlags_t
- txPhys – **[in]** Host preferences on Tx Phy, as defined by gapLePhyFlags_t, ignored for gLeTxPhyNoPreference_c
- rxPhys – **[in]** Host preferences on Rx Phy, as defined by gapLePhyFlags_t, ignored for gLeRxPhyNoPreference_c

- phyOptions – **[in]** Host preferences on Coded Phy, as defined by gapLePhyOptionsFlags_t Ignored if defaultMode is TRUE.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version

bleResult_t Gap_ControllerEnhancedNotification(uint16_t eventType, *deviceId_t* deviceId)

Configures enhanced notifications on advertising, scanning and connection events on the controller.

Remark

The application should listen for the gControllerNotificationEvent_c generic event.

Remark

This function executes synchronously.

Parameters

- eventType – **[in]** Event type selection as specified by bleNotificationEventType_t.
- deviceId – **[in]** Device ID of the peer, used only for connection events.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory.

bleResult_t Gap_BleAdvIndexChange(*bleAdvIndexType_t* advIndexType, uint8_t aUserDefinedChannels[3])

This function configures the advertising index type.

Parameters

- advIndexType – **[in]** Advertising index type
- aUserDefinedChannels – **[in]** User defined channels array

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_LoadKeys(uint8_t nvmIndex, *gapSmpKeys_t* *pOutKeys, *gapSmpKeyFlags_t* *pOutKeyFlags, bool_t *pOutLeSc, bool_t *pOutAuth)

Retrieves the keys from an existing bond with a device.

Remark

This API requires that the aAddress in the pOutKeys shall not be NULL.

Remark

The application will check pOutKeyFlags to see which information is valid in pOutKeys.

Remark

This function executes synchronously.

Parameters

- nvmIndex – **[in]** Index of the device in the NVM bonding area.
- pOutKeys – **[out]** Pointer to fill the keys distributed during pairing.
- pOutKeyFlags – **[out]** Pointer to indicate which keys were distributed during pairing.
- pOutLeSc – **[out]** Pointer to mark if LE Secure Connections was used during pairing.
- pOutAuth – **[out]** Pointer to mark if the device was authenticated for MITM during pairing.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_SaveKeys(uint8_t nvmIndex, const *gapSmpKeys_t* *pKeys, bool_t leSc, bool_t auth)

Saves the keys to a new or existing bond based on OOB information.

Remark

This API requires that the aAddress in the pKeys shall not be NULL.

Remark

If any of the keys are passed as NULL, they will not be saved.

Remark

The application listen for gBondCreatedEvent_c to confirm the bond was created.

Parameters

- nvmIndex – **[in]** Index of the device in the NVM bonding area.
- pKeys – **[in]** Pointer to the keys distributed during pairing.
- leSc – **[in]** Indicates if LE Secure Connections was used during pairing.
- auth – **[in]** Indicates if the device was authenticated for MITM during pairing.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetChannelMap(const *bleChannelMap_t* channelMap)

Set the channel map in the Controller and trigger an LL channel map update. Specifies the channel map for data, secondary advertising and periodic physical channels.

Remark

The application should listen for the gChannelMapSet_c generic event.

Remark

This function executes synchronously.

Remark

API supported on GAP Central devices or Broadcaster with Extended Advertising support.

Parameters

- channelMap – **[in]** Array with the channels using 0 for bad channels and 1 for unknown.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.

bleResult_t Gap_ReadChannelMap(*deviceId_t* deviceId)

Reads the channel map of a connection.

Remark

The application should listen for the gConnEvtChannelMapRead_c connection event.

Remark

This function executes synchronously.

Parameters

- deviceId – **[in]** Device ID of the peer.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_SetExtAdvertisingParameters(*gapExtAdvertisingParameters_t* *pAdvertisingParameters)

Sets up the Extended Advertising Parameters.

Remark

GAP Peripheral-only API function.

Parameters

- pAdvertisingParameters – **[in]** Pointer to gapExtAdvertisingParameters_t structure.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gGapAnotherProcedureInProgress_c – Another set extended advertisment parameters command is in progress.

bleResult_t Gap_SetExtAdvertisingParametersV2(*gapExtAdvertisingParametersV2_t* *pAdvertisingParameters)

Sets up the Extended Advertising Parameters. V2 of the command.

Remark

GAP Peripheral-only API function.

Parameters

- pAdvertisingParametersV2 – **[in]** Pointer to gapExtAdvertisingParametersV2_t structure.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gGapAnotherProcedureInProgress_c – Another set extended advertising parameters command is in progress.

bleResult_t Gap_SetExtAdvertisingData(uint8_t handle, *gapAdvertisingData_t* *pAdvertisingData, *gapScanResponseData_t* *pScanResponseData)

Sets up the Extended Advertising and Extended Scan Response Data.

Remark

Any of the parameters may be NULL, in which case they are ignored. Therefore, this function can be used to set any of the parameters individually or both at once.

Remark

GAP Peripheral-only API function.

Parameters

- handle – **[in]** The ID of the advertising set
- pAdvertisingData – **[in]** Pointer to *gapAdvertisingData_t* structure or NULL.
- pScanResponseData – **[in]** Pointer to gapScanResponseData_t structure or NULL.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleInvalidState_c – The advertising set was not configured previously using Gap_SetExtAdvertisingParameters.
- gGapAdvDataTooLong_c – The advertising data is too long.

bleResult_t Gap_SetExtAdvertisingDecisionData(uint8_t handle, const *gapAdvertisingDecisionData_t* *pAdvertisingDecisionData)

Sets up the Extended Advertising Decision Data.

Remark

pDecisionData or pKey in the *gapAdvertisingDecisionData_t* structure may be NULL but not both.

Remark

GAP Peripheral-only API function.

Remark

Application should wait for gExtAdvertisingDecisionDataSetupComplete_c or generic event or for gInternalError_c generic event with errorSource = gSetExtAdvDecisionData_c.

Parameters

- handle – **[in]** The ID of the advertising set
- pAdvertisingDecisionData – **[in]** Pointer to *gapAdvertisingDecisionData_t* structure.

Return values

- gBleFeatureNotSupported_c – in case gLeExtendedAdv_c or gLeDecisionBasedAdvertisingFiltering_c are not supported.
- gBleInvalidParameter_c – in case at least 1 parameter is incorrect.
- gBleOutOfMemory_c – in case the memory allocation for the app to host message fails.
- gBleSuccess_c – otherwise.

bleResult_t Gap_StartExtAdvertising(*gapAdvertisingCallback_t* advertisingCallback, *gapConnectionCallback_t* connectionCallback, uint8_t handle, uint16_t duration, uint8_t maxExtAdvEvents)

Commands the controller to start the extended advertising.

Remark

The advertisingCallback confirms or denies whether the advertising has started. The connectionCallback is only used if a connection gets established during advertising.

Remark

GAP Peripheral-only API function.

Parameters

- advertisingCallback – **[in]** Callback used by the application to receive advertising events. Can be NULL.

- connectionCallback – **[in]** Callback used by the application to receive connection events. Can be NULL.
- handle – **[in]** The ID of the advertising set
- duration – **[in]** The duration of the advertising
- maxExtAdvEvents – **[in]** The maximum number of advertising events

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidState_c – The advertising is already started or pending to be started.

bleResult_t Gap_StopExtAdvertising(uint8_t handle)

Commands the controller to stop extended advertising for set ID.

Remark

GAP Peripheral-only API function.

Parameters

- handle – **[in]** The ID of the advertising set

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleInvalidState_c – The advertising set is not started.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_RemoveAdvSet(uint8_t handle)

Commands the controller to remove the specified advertising set and all its data.

Remark

GAP Peripheral-only API function.

Parameters

- handle – **[in]** The ID of the advertising set

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetPeriodicAdvParameters(*gapPeriodicAdvParameters_t* *pAdvertisingParameters)

Sets up the Periodic Advertising Parameters.

Remark

GAP Peripheral-only API function.

Parameters

- pAdvertisingParameters – **[in]** Pointer to gapPeriodicAdvParameters_t structure.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetPeriodicAdvParametersV2(*gapPeriodicAdvParametersV2_t* *pAdvertisingParameters)

Sets up the Periodic Advertising Parameters - v2 of the command.

Remark

GAP Peripheral-only API function.

Parameters

- pAdvertisingParameters – **[in]** Pointer to gapPeriodicAdvParametersV2_t structure.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetPeriodicAdvSubeventData(uint8_t advHandle, const *gapPeriodicAdvertisingSubeventData_t* *pData)

Sets up the Periodic Advertising Subevent Data.

Remark

GAP Peripheral-only API function.

Parameters

- advHandle – **[in]** Advertising handle.
- gapPeriodicAdvertisingSubeventData_t – Pointer to *gapPeriodicAdvertisingSubeventData_t* structure.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetPeriodicAdvResponseData(uint16_t syncHandle, const *gapPeriodicAdvertisingResponseData_t* *pData)

Sets up the Periodic Advertising Response Data.

Parameters

- syncHandle – **[in]** Sync handle.
- gapPeriodicAdvertisingResponseData_t – Pointer to *gapPeriodicAdvertisingResponseData_t* structure.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetPeriodicSyncSubevent(uint16_t syncHandle, const *gapPeriodicSyncSubeventParameters_t* *pParams)

Instructs the controller to sync with a subset of the subevents within a PAWR train identified by syncHandle.

Parameters

- syncHandle – **[in]** Sync handle.
- gapPeriodicSyncSubeventParameters_t – Pointer to *gapPeriodicSyncSubeventParameters_t* structure.

Return values

- gBleSuccess_c –

- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetPeriodicAdvertisingData(uint8_t handle, *gapAdvertisingData_t* *pAdvertisingData, bool_t bUpdateDID)

Sets up the Periodic Advertising Data.

Remark

GAP Peripheral-only API function.

Parameters

- handle – **[in]** The ID of the periodic advertising set
- pAdvertisingData – **[in]** Pointer to *gapAdvertisingData_t* structure.
- bUpdateDid – **[in]** If TRUE, use operation mode gHciExtDataUnchanged_c.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleInvalidState_c – The advertising set was not previously configured using Gap_SetPeriodicAdvParameters.
- gGapAdvDataTooLong_c – The advertising data is too long.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_StartPeriodicAdvertising(uint8_t handle, bool_t bIncludeADI)

Commands the controller to start periodic advertising for set ID.

Remark

GAP Peripheral-only API function.

Parameters

- handle – **[in]** The ID of the periodic advertising set
- bIncludeADI – **[in]** If TRUE, include ADI field in AUX_SYNC_IND PDUs

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.

- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleInvalidState_c – The advertising set was not previously configured using Gap_SetPeriodicAdvParameters.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_StopPeriodicAdvertising(uint8_t handle)

Commands the controller to stop periodic advertising for set ID.

Remark

GAP Peripheral-only API function.

Parameters

- handle – **[in]** The ID of the periodic advertising set

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleInvalidState_c – The advertising set was not previously configured using Gap_SetPeriodicAdvParameters.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_UpdatePeriodicAdvList(*gapPeriodicAdvListOperation_t* operation, *bleAddressType_t* addrType, uint8_t *pAddr, uint8_t SID)

Manage the periodic advertising list.

Remark

GAP Central-only API function.

Parameters

- operation – **[in]** The list operation: add/remove a device, or clear all.
- addrType – **[in]** The address type of the periodic advertiser.
- pAddr – **[in]** Pointer to the advertiser's address.
- SID – **[in]** The ID of the advertising set.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

- gGapAnotherProcedureInProgress_c – Periodic advertising create sync is in progress.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_PeriodicAdvCreateSync(*gapPeriodicAdvSyncReq_t* *pReq)

Start tracking periodic advertisements. Scanning is required to be ON for this request to be processed, so the scanning callback will receive the periodic advertising events.

Remark

GAP Central-only API function.

Parameters

- pReq – **[in]** Pointer to the Sync Request parameters.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gGapAnotherProcedureInProgress_c – Periodic advertising create sync is in progress.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_PeriodicAdvTerminateSync(uint16_t syncHandle)

Stop tracking periodic advertisements.

Remark

GAP Central-only API function.

Parameters

- syncHandle – **[in]** Used to identify the periodic advertiser

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gGapAnotherProcedureInProgress_c – Periodic advertising create sync is in progress.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_PeriodicAdvReceiveEnable(uint16_t syncHandle, bool_t enableDuplicateFiltering)

Enable Periodic Advertisement Sync Transfer Controller feature.

Parameters

- syncHandle – **[in]** Used to identify the periodic advertiser
- enableDuplicateFiltering – **[in]** Used to enable or disable duplicate filtering

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_PeriodicAdvReceiveDisable(uint16_t syncHandle)

Disable Periodic Advertisement Sync Transfer Controller feature.

Parameters

- syncHandle – **[in]** Used to identify the periodic advertiser

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_PeriodicAdvSyncTransfer(*gapPeriodicAdvSyncTransfer_t* *pParam)

Instruct the Controller to send synchronization information about the periodic advertising train identified by the sync handle to a connected device.

Parameters

- pParam – **[in]** Pointer to the command arguments

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_PeriodicAdvSetInfoTransfer(*gapPeriodicAdvSetInfoTransfer_t* *pParam)

Instruct the Controller to send synchronization information about the periodic advertising to a connected device.

Parameters

- pParam – **[in]** Pointer to the command arguments

Return values

- gBleSuccess_c –

- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetPeriodicAdvSyncTransferParams(*gapSetPeriodicAdvSyncTransferParams_t* *pParam)

Specify how the Controller will process periodic advertising synchronization information received from the device identified by the device id.

Parameters

- pParam – **[in]** Pointer to the command arguments

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetDefaultPeriodicAdvSyncTransferParams(*gapSetPeriodicAdvSyncTransferParams_t* *pParam)

Specify the initial value for the mode, skip, timeout, and Constant Tone Extension type (set by the Gap_SetPeriodicAdvSyncTransferParams command) to be used for all subsequent connections over the LE transport.

Parameters

- pParam – **[in]** Pointer to the command arguments

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_ResumeLeScStateMachine(computeDhKeyParam_t *pData)

Resume the pairing process. At this point the ECDH key must be computed. This function should be called only for secured LE connections. In any other cases the user should make his own code for handling the case when the ECDH computation is completed.

Parameters

- pData – **[in]** Pointer to the data used to resume the host state machine. The data is allocated by the stack when it requests an ECDH multiplication. It is also freed by the stack at the end of the multiplication.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_SetConnectionlessCteTransmitParameters(*gapConnectionlessCteTransmitParams_t* *pTransmitParams)

Set Connectionless CTE Transmit Parameters for an advertising set.

Parameters

- pTransmitParams – **[in]** Pointer to struct containing parameters.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnableConnectionlessCteTransmit(uint8_t handle, *bleCteTransmitEnable_t* enable)

Enable or disable Connectionless CTE Transmit for an advertising set.

Parameters

- handle – **[in]** Advertising set handle.
- enable – **[in]** Enable or disable CTE Transmit.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnableConnectionlessIqSampling(uint16_t syncHandle, *gapConnectionlessIqSamplingParams_t* *pIqSamplingParams)

Enable or disable Connectionless IQ sampling for an advertising train.

Parameters

- syncHandle – **[in]** Used to identify advertising train.
- pIqSamplingParams – **[in]** Pointer to struct containing parameters.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetConnectionCteReceiveParameters(*deviceId_t* deviceId, *gapConnectionCteReceiveParams_t* *pReceiveParams)

Set CTE Receive Parameters for a certain connection.

Parameters

- deviceId – **[in]** Peer device ID.
- pReceiveParams – **[in]** Pointer to struct containing parameters.

Return values

- gBleSuccess_c –

- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetConnectionCteTransmitParameters(*deviceId_t* deviceId, *gapConnectionCteTransmitParams_t* *pTransmitParams)

Set CTE Transmit Parameters for a certain connection.

Parameters

- deviceId – **[in]** Peer device ID.
- pTransmitParams – **[in]** Pointer to struct containing parameters.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnableConnectionCteRequest(*deviceId_t* deviceId, *gapConnectionCteReqEnableParams_t* *pCteReqEnableParams)

Enable or disable CTE Request procedure for a certain connection.

Parameters

- deviceId – **[in]** Peer device ID.
- pCteReqEnableParams – **[in]** Pointer to struct containing parameters.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnableConnectionCteResponse(*deviceId_t* deviceId, *bleCteRspEnable_t* enable)

Enable or disable sending CTE Responses for a certain connection.

Parameters

- deviceId – **[in]** Peer device ID.
- enable – **[in]** Enable or disable sending CTE Responses.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_ReadAntennaInformation(void)

Read Antenna Information.

Remark

Antenna information contained in gAntennaInformationRead_c generic event.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnhancedReadTransmitPowerLevel(*deviceId_t* deviceId, *blePowerControlPhyType_t* phy)

Read local current and maximum tx power levels for a certain connection and PHY.

Parameters

- deviceId – **[in]** Peer device ID.
- phy – **[in]** PHY.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_ReadRemoteTransmitPowerLevel(*deviceId_t* deviceId, *blePowerControlPhyType_t* phy)

Read remote tx power for a certain connection and PHY.

Parameters

- deviceId – **[in]** Peer device ID.
- phy – **[in]** PHY.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetPathLossReportingParameters(*deviceId_t* deviceId, *gapPathLossReportingParams_t* *pPathLossReportingParams)

Set path loss threshold reporting parameters for a certain connection.

Parameters

- deviceId – **[in]** Peer device ID.
- pPathLossReportingParams – **[in]** Pointer to struct containing parameters.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnablePathLossReporting(*deviceId_t* deviceId, *blePathLossReportingEnable_t* enable)

Enable or disable path loss threshold reporting for a certain connection.

Parameters

- deviceId – **[in]** Peer device ID.
- enable – **[in]** Enable or disable path loss threshold reporting.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnableTransmitPowerReporting(*deviceId_t* deviceId, *bleTxPowerReportingEnable_t* localEnable, *bleTxPowerReportingEnable_t* remoteEnable)

Enable or disable tx power reporting for a certain connection.

Parameters

- deviceId – **[in]** Peer device ID.
- localEnable – **[in]** Enable or disable local tx power reports.
- removeEnable – **[in]** Enable or disable remote tx power reports.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_GenerateDhKeyV2(ecdhPublicKey_t *pRemoteP256PublicKey, *gapPrivateKeyType_t* keyType)

Initiates generation of a Diffie-Hellman key in the Controller for use over the LE transport. Version 2 of LE Generate DHKey command.

Remark

Generated key is contained in gHciLeGenerateDhKeyCompleteEvent_c event.

Parameters

- pRemoteP256PublicKey – **[in]** Pointer to the remote P-256 public key used as input for DH key generation.
- keyType – **[in]** The private key used of DH key generation.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EattConnectionRequest(*deviceId_t* deviceId, uint16_t mtu, uint8_t cBearers, uint16_t initialCredits, bool_t autoCreditsMgmt)

Open up to 5 Enhanced ATT bearers.

Parameters

- deviceId – **[in]** Peer device id
- mtu – **[in]** MTU
- cBearers – **[in]** Number of bearers
- initialCredits – **[in]** Initial credits
- autoCreditsMgmt – **[in]** EATT will automatically send credits in chunks of initialCredits if TRUE.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EattConnectionAccept(*deviceId_t* deviceId, bool_t accept, uint16_t localMtu, uint16_t initialCredits, bool_t autoCreditsMgmt)

Accept or reject a received EATT Connection Request.

Parameters

- deviceId – **[in]** Peer device id
- accept – **[in]** TRUE - accept received EattConnectionRequest FALSE - reject incoming EattConnectionRequest
- localMtu – **[in]** Local MTU
- Initial (initialCredits,) – **[in]** credits
- autoCreditsMgmt – **[in]** EATT will automatically send credits in chunks of initialCredits if TRUE.

Return values

- gBleSuccess_c –

- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EattReconfigureRequest(*deviceId_t* deviceId, uint16_t mtu, uint16_t mps, uint8_t cBearers, *bearerId_t* *pBearers)

Reconfigure the MTU of up to 5 Enhanced ATT bearers.

Parameters

- deviceId – **[in]** Peer device id
- mtu – **[in]** New MTU value to be configured.
- mps – **[in]** New MPS value to be configured. Set to 0 to use current maximum mps value of the channels being reconfigured
- cBearers – **[in]** Number of bearers
- *pBearers – **[in]** Initial credits

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EattSendCredits(*deviceId_t* deviceId, *bearerId_t* bearerId, uint16_t credits)

Send L2cap credits for Enhanced ATT bearers.

Parameters

- deviceId – **[in]** Peer device id
- bearerId – **[in]** Enhanced ATT bearer id.
- credits – **[in]** Number of credits.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EattDisconnect(*deviceId_t* deviceId, *bearerId_t* bearerId)

Disconnect the specified bearer.

Parameters

- deviceId – **[in]** Peer device id
- bearerId – **[in]** Enhanced ATT bearer id to be disconnected.

Return values

- gBleSuccess_c –

- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_GetDeviceIdFromConnHandle(uint16_t connHandle, *deviceId_t* *pDeviceId)

Returns the deviceId associated with the received connection handle.

Parameters

- connHandle – **[in]** Connection identifier
- pDeviceId – **[out]** Corresponding device id

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_GetConnectionHandleFromDeviceId(*deviceId_t* deviceId, uint16_t *pConnHandle)

Returns the deviceId associated with the received connection handle.

Parameters

- deviceId – **[in]** Connection identifier
- pConnHandle – **[out]** Corresponding connection handle

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_GetHostVersion(*gapHostVersion_t* *pOutHostVersion)

Retrieves Host Version information.

Parameters

- pOutHostVersion – **[out]** Pointer to the memory location where the Host Version information should be stored.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_ReadRemoteVersionInformation(*deviceId_t* deviceId)

Reads the version information of a peer device.

Parameters

- deviceId – **[in]** Peer device identifier.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_GetConnParamsMonitoring(*deviceId_t* deviceId, uint8_t mode)

Get the Connection parameters for the given deviceId in the given mode.

Parameters

- deviceId – **[in]** Peer device Id.
- mode – **[in]** Connection parameters event report mode: bit 0: update the local sequence number for central / peripheral differentiation and send the LE_Handover_Connection_Parameters_Update_Event after remote sequence number change. bit 1: Send LE_Handover_Connection_Parameters_Update_Event when the connection parameters are updated following an LL procedure

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeChannelOverride(*bleChannelOverrideMode_t* mode, uint8_t channelListLength, uint8_t *pChannelList)

This function sets the channels to be used for advertising, scanning or initiation.

If the mode is 0x00 (advertising), the specified channels are used by the following advertising commands. The channels used by the ongoing advertising will not change until the advertising is disabled, even if a new channel override command with mode 0x00 is received. This allows different advertising channels for different advertising sets. The mode 0x00 (advertising) can be issued when an advertising is ongoing. The setting will be used by the next advertising enable command.

Remark

In the channel list, the MSB of each byte indicates if the channel is BLE channel index or generic channel index:

- BLE channel index: 0 to 39
- Generic channel index: 0x80+0 to 0x80+127

If the mode is 0x01 or 0x02 (scan or initiation), the specified channels are used by the following scan and initiation. The command with mode 0x01 or 0x02 should be issued when the scan or initiation is not ongoing.

When a generic channel is used, the whitening is initialized by the lower 6 bits of the generic channel index. When a BLE channel is used, the whitening is initialized by the BLE channel index. So the BLE channel 37/38/39 are not strictly the same as the generic channels 42/66/120: they operate on the same frequency but their channel whitening is different.

Parameters

- mode – **[in]** Override the advertising, scanning or initiation channels.
- channelListLength – **[in]** Length of channel list, must be between 1 and 6.
- pChannelList – **[in]** List of channels (see remarks for more details).

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – One or more parameters are invalid.

- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeSetSchedulerPriority(uint16_t priorityHandle)

This function sets the priority for one connection in case of several connections by calling the corresponding HCI command.

Parameters

- priorityHandle – **[in]** Parameter that sets the priority for connections

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeSetHostFeature(uint8_t bitNumber, bool_t enable)

This function is used by the Host to set or clear a bit controlled by the Host in the Link Layer FeatureSet.

Parameters

- bitNumber – **[in]** Bit position in the FeatureSet
- enable – **[in]** Host feature is enabled/disabled

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EncryptAdvertisingData(const *gapAdvertisingData_t* *pAdvertisingData, const uint8_t *pKey, const uint8_t *pIV, uint8_t *pOutput)

This function is used to encrypt a series of AD structures into an encrypted AD structure.

Parameters

- pAdvertisingData – **[in]** Pointer to AD(s) to be encrypted.
- pKey – **[in]** Pointer to 16-byte key to be used for encryption (must be big endian).
- pIV – **[in]** Pointer to 8-byte initialization vector (must be little endian).
- pOutput – **[out]** Pointer for location of output encrypted data. Must be large enough to accommodate the size of the total data to be encrypted plus the size of the Randomizer and MIC fields.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – At least one of the provided parameters is invalid.
- gBleOutOfMemory_c – Could not allocate memory for the buffers used in CCM.
- gBleRngError_c – Could not generate the randomizer.
- gBleSecLibError_c – CCM call failed.

bleResult_t Gap_DecryptAdvertisingData(uint8_t *pData, uint16_t dataLength, const uint8_t *pKey, const uint8_t *pIV, uint8_t *pOutput)

This function is used to decrypt advertising data.

Parameters

- pData – **[in]** Pointer to encrypted data (AD payload).
- dataLength – **[in]** Length of the encrypted data (includes randomizer and MIC fields).

- pKey – **[in]** Pointer to 16-byte key to be used for decryption (must be big endian).
- pIV – **[in]** Pointer to 8-byte initialization vector (must be little endian).
- pOutput – **[out]** Pointer to the location of decrypted data.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – At least one of the provided parameters is invalid.
- gBleOutOfMemory_c – Could not allocate memory for the buffers used in CCM.
- gBleSecLibError_c – CCM call failed.

void Gap_SetConnectionCallback(*gapConnectionCallback_t* pfConnectionCallback)

Set the GAP connection callback.

Parameters

- pfConnectionCallback – **[in]** The function called when one of the events defined in gapConnectionEventType_t occurs.

Returns

none

void Gap_SetScanningCallback(*gapScanningCallback_t* pfScanningCallback)

Set the GAP scanning callback.

Parameters

- pfScanningCallback – **[in]** The function called when one of the events defined in gapScanningEventType_t occurs.

Returns

none

Gap_AddSecurityModesAndLevels(modeLevelA, modeLevelB)

Macro used to combine two security mode-levels.

Remark

This macro is useful when two different security requirements must be satisfied at the same time, such as a device central security requirement and a service-specific security requirement.

Parameters

- modeLevelB (modeLevelA,) – **[in]** The two security mode-levels.

Returns

The resulting security mode-level.

Gap_CancelInitiatingConnection()

Macro used to cancel a connection initiated by Gap_Connect(...).

Remark

This macro can only be used for a connection that has not yet been established, such as the "gConnEvtConnected_c" has not been received. For example, call this when a connection request has timed out. Application should listen for gCreateConnectionCanceled_c generic event.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

Gap_ReadAdvertisingTxPowerLevel()

Macro used to read the radio transmitter power when advertising.

Remark

The result is contained in the gAdvTxPowerLevelRead_c generic event.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

Gap_ReadRssi(deviceId)

Macro used to read the RSSI of a radio connection.

Remark

The result is contained in the gConnEvtRssiRead_c connection event. The RSSI value is a signed byte, and the unit is dBm. If the RSSI cannot be read, the gConnEvtPowerReadFailure_c connection event is generated.

Parameters

- deviceId – **[in]** Device ID identifying the radio connection.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

Gap_ReadTxPowerLevelInConnection(deviceId)

Macro used to read the radio transmitting power level of a radio connection.

Remark

The result is contained in the gConnEvtTxPowerLevelRead_c connection event. If the TX Power cannot be read, the gConnEvtPowerReadFailure_c connection event is generated.

Parameters

- deviceId – **[in]** Device ID identifying the radio connection.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

Gap_GetConnParams(deviceId)

Get the Connection parameters for the given deviceId.

Parameters

- deviceId – **[in]** Peer device Id.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

gCancelOngoingInitiatingConnection_d

Use this value as a parameter to the Gap_Disconnect(deviceId) function to cancel any ongoing connection initiation, for example if the connection has timed out.

gMode_2_Mask_d

Mask to check if a Security Mode-and-Level is Mode 2

getSecurityLevel(modeLevel)

Extracts the security level (see gapSecurityLevel_t) from the combined security mode-level (gapSecurityModeAndLevel_t).

getSecurityMode(modeLevel)

Extracts the security mode (see gapSecurityMode_t) from the combined security mode-level (gapSecurityModeAndLevel_t).

isMode_2(modeLevel)

isMode_1(modeLevel)

isSameMode(modeLevelA, modeLevelB)

addSameSecurityModes(modeLevelA, modeLevelB)

addMode1AndMode2(mode1, mode2)

addDifferentSecurityModes(modeLevelA, modeLevelB)

gDefaultEncryptionKeySize_d

The default (minimum) value for the LTK size

gMaxEncryptionKeySize_d

The maximum value for the LTK size

gGapDefaultDeviceSecurity_d

The default value for the Device Security (no requirements)

gGapDefaultSecurityRequirements_d
: The default value for a Security Requirement

gGapAdvertisingIntervalRangeMinimum_c
: Minimum advertising interval (20 ms)

gGapAdvertisingIntervalDefault_c
: Default advertising interval (1.28 s)

gGapAdvertisingIntervalRangeMaximum_c
: Maximum advertising interval (10.24 s)

gGapExtAdvertisingIntervalRangeMinimum_c
: Minimum extended advertising interval (20 ms)

gGapExtAdvertisingIntervalDefault_c
: Default extended advertising interval (1.28 s)

gGapExtAdvertisingIntervalRangeMaximum_c
: Maximum extended advertising interval (10485.76 s)

gGapPeriodicAdvIntervalRangeMinimum_c
: Minimum periodic advertising interval (7.5 ms)

gGapPeriodicAdvIntervalDefault_c
: Default periodic advertising interval (2.56 s)

gGapPeriodicAdvIntervalRangeMaximum_c
: Maximum periodic advertising interval (81.91875 s)

gGapAdvertisingChannelMapDefault_c
: Default Advertising Channel Map - all 3 channels are enabled

gGapDefaultAdvertisingParameters_d
: Default value for Advertising Parameters struct

gGapDefaultExtAdvertisingParameters_d
: Default value for Extended Advertising Parameters struct

gGapDefaultPeriodicAdvParameters_d
: Default value for Periodic Advertising Parameters struct

gGapScanIntervalMin_d
: Minimum scan interval (2.5 ms)

gGapScanIntervalDefault_d
: Default scan interval (10 ms)

gGapScanIntervalMax_d
: Maximum scan interval (10.24 s)

gGapScanWindowMin_d
: Minimum scan window (2.5 ms)

gGapScanWindowDefault_d
: Default scan window (10 ms)

gGapScanWindowMax_d
: Maximum scan window (10.24 s)

gGapRssiMin_d
: Minimum valid value for RSSI (dB)

gGapRssiMax_d
: Maximum valid value for RSSI (dB)

gGapRssiNotAvailable_d
: A special invalid value for the RSSI indicating that the measurement is not available.

gGapScanContinuously_d
: Default value for Scanning duration - Scan continuously until explicitly disable

gGapScanPeriodicDisabled_d
: Default value for Scanning period - Periodic scanning disabled

gGapDefaultScanningParameters_d
: Default value for Scanning Parameters struct

gGapConnIntervalMin_d
: Minimum connection interval (7.5 ms)

gGapConnIntervalMax_d
: Maximum connection interval (4 s)

gGapConnLatencyMin_d
: Minimum connection latency value (0 - no connection event may be ignored)

gGapConnLatencyMax_d
: Maximum connection latency value (499 connection events may be ignored)

gGapConnSuperTimeoutMin_d
: Minimum supervision timeout (100 ms)

gGapConnSuperTimeoutMax_d
: Maximum supervision timeout (32 s)

gGapConnEventLengthMin_d
: Minimum value of the connection event length (0 ms)

gGapConnEventLengthMax_d
: Maximum value of the connection event length (~41 s)

gGapDefaultConnectionLatency_d
: Default connection latency: 0

gGapDefaultSupervisionTimeout_d
: Default supervision timeout: 10s

gGapDefaultMinConnectionInterval_d
: Default minimum connection interval: 100ms

gGapDefaultMaxConnectionInterval_d
: Default maximum connection interval: 200ms

gGapDefaultConnectionRequestParameters_d
: The default value for the Connection Request Parameters structure

gGapChSelAlgorithmNo2
: “Channel Selection Algorithm #2 is used” value in LE Channel Selection Algorithm Event

gBlePeriodicAdvOngoingSyncCancelHandle
: Sync handle value for which to call the create sync cancel command instead of terminate sync

gGapInvalidSyncHandle
: Sync handle used to differentiate extended advertising reports from periodic advertising reports

gNone_c
: Values of the AD Flags advertising data structure. No information.

gLeLimitedDiscoverableMode_c
: This device is in Limited Discoverable mode.

gLeGeneralDiscoverableMode_c
: This device is in General Discoverable mode.

gBrEdrNotSupported_c
: This device supports only Bluetooth Low Energy; no support for Classic Bluetooth.

gSimultaneousLeBrEdrCapableController_c
: This device’s Controller also supports Classic Bluetooth.

gSimultaneousLeBrEdrCapableHost_c
: This device’s Host also supports Classic Bluetooth.

gNoKeys_c

Flags indicating the Keys to be exchanged by the SMP during the key exchange phase of pairing. No key can be distributed.

gLtk_c

Long Term Key.

gIrk_c

Identity Resolving Key.

gCsrk_c

Connection Signature Resolving Key.

gSecurityMode_1_c

LE Security Mode values for gapSecurityMode_t Mode 1 - Encryption required (except for Level 1).

gSecurityMode_2_c

Mode 2 - Data Signing required.

gSecurityLevel_NoSecurity_c

LE Security Level values for gapSecurityLevel_t No security (combined only with Mode 1).

gSecurityLevel_NoMitmProtection_c

Unauthenticated (no MITM protection).

gSecurityLevel_WithMitmProtection_c

Authenticated (MITM protection by PIN or OOB).

gSecurityLevel_LeSecureConnections_c

Authenticated with LE Secure Connections.

gSecurityMode_1_Level_1_c

Security Mode-and-Level definitions values for gapSecurityModeAndLevel_t Mode 1 Level 1 - No Security.

gSecurityMode_1_Level_2_c

Mode 1 Level 2 - Encryption without authentication.

gSecurityMode_1_Level_3_c

Mode 1 Level 3 - Encryption with authentication.

gSecurityMode_1_Level_4_c

Mode 1 Level 4 - Encryption with LE Secure Connections pairing.

gSecurityMode_2_Level_1_c

Mode 2 Level 1 - Data Signing without authentication.

gSecurityMode_2_Level_2_c

Mode 2 Level 2 - Data Signing with authentication.

gOobNotAvailable_c

Reason for rejecting the pairing request used by gapAuthenticationRejectReason_t. These values are equal to the corresponding reasons from SMP. This device does not have the required OOB for authenticated pairing.

gIncompatibleIoCapabilities_c

The combination of I/O capabilities does not allow pairing with the desired level of security.

gPairingNotSupported_c

This device does not support pairing.

gLowEncryptionKeySize_c

The peer's encryption key size is too low for this device's required security level.

gUnspecifiedReason_c

The host has rejected the pairing for an unknown reason.

gRepeatedAttempts_c

This device is the target of repeated unsuccessful pairing attempts and does not allow further pairing attempts at the moment.

gLinkEncryptionFailed_c

Link could not be encrypted. This reason may not be used by Gap_RejectPairing!

gIoDisplayOnly_c

I/O Capabilities as defined by the SMP used by gapIoCapabilities_t May display a PIN, no input.

gIoDisplayYesNo_c

May display a PIN and has a binary input (e.g., YES and NO buttons).

gIoKeyboardOnly_c

Has keyboard input, no display.

gIoNone_c

No input and no display.

gIoKeyboardDisplay_c

Has keyboard input and display.

gGapCteMinLength_c

AoA/AoD Min CTE length in 8 us units.

gGapCteMaxLength_c

Max CTE length in 8 us units.

gGapCteMinCount_c

Min number of CTEs to transmit in each periodic advertising interval.

gGapCteMaxCount_c

Max number of CTEs to transmit in each periodic advertising interval.

gGapMinSwitchingPatternLength_c

Min number of antennae in the pattern.

gGapMaxSwitchingPatternLength_c

Max number of antennae in the pattern.

gGapEattMaxBearers

Maximum number of bearer Ids in one GAP request/response.

gbmpDIAM_NonConnectableNonScannableUndirected_c

gbmpDIAM_ConnectableUndirected_c

gbmpDIAM_ScannableUndirected_c

struct gapSmpKeys_t

#include <gap_types.h> Structure containing the SMP information exchanged during pairing.

Public Members

uint8_t cLtkSize

Encryption Key Size. If aLtk is NULL, this is ignored.

uint8_t *aLtk

Long Term (Encryption) Key. NULL if LTK is not distributed, else size is given by cLtkSize.

uint8_t *aIrk

Identity Resolving Key. NULL if aIrk is not distributed.

uint8_t *aCsrk

Connection Signature Resolving Key. NULL if aCsrk is not distributed.

uint8_t cRandSize

Size of RAND; usually equal to gcMaxRandSize_d. If aLtk is NULL, this is ignored.

uint8_t *aRand

RAND value used to identify the LTK. If aLtk is NULL, this is ignored.

uint16_t ediv

EDIV value used to identify the LTK. If aLtk is NULL, this is ignored.

bleAddressType_t addressType

Public or Random address. If aAddress is NULL, this is ignored.

uint8_t *aAddress

Device Address. NULL if address is not distributed. If aIrk is NULL, this is ignored.

struct gapSecurityRequirements_t

#include <gap_types.h> Security Requirements structure for a Device, a Service or a Characteristic

Public Members

gapSecurityModeAndLevel_t securityModeLevel

Security mode and level.

bool_t authorization

Authorization required.

uint16_t minimumEncryptionKeySize

Minimum encryption key (LTK) size. Ignored if gSecurityMode_1_Level_4_c is required (set to gMaxEncryptionKeySize_d automatically)

struct gapServiceSecurityRequirements_t

#include <gap_types.h> Service Security Requirements

Public Members

uint16_t serviceHandle

Handle of the Service declaration in the GATT Database.

gapSecurityRequirements_t requirements

Requirements for all attributes in this service.

struct gapDeviceSecurityRequirements_t

#include <gap_types.h> Device Security - Security Requirements + Service Security Requirements

Public Members

gapSecurityRequirements_t *pSecurityRequirements

Security requirements added to all services.

uint8_t cNumServices

Number of service-specific requirements; must be less than or equal to gcGapMaxServiceSpecificSecurityRequirements_c.

gapServiceSecurityRequirements_t *aServiceSecurityRequirements

Array of service-specific requirements.

struct gapHandleList_t

#include <gap_types.h> List of Attribute Handles for authorization lists.

Public Members

uint8_t cNumHandles

Number of handles in this list.

uint16_t aHandles[(1U)]

List of handles.

struct gapConnectionSecurityInformation_t

#include <gap_types.h> Connection Security Information structure

Public Members

bool_t authenticated

TRUE if pairing was performed with MITM protection.

gapHandleList_t authorizedToRead

List of handles the peer has been authorized to read.

gapHandleList_t authorizedToWrite

List of handles the peer has been authorized to write.

struct gapPairingParameters_t

#include <gap_types.h> Pairing parameters structure for the Gap_Pair and Gap_AcceptPairingRequest APIs

Public Members

bool_t withBonding

TRUE if this device is able to and wants to bond after pairing, FALSE otherwise.

gapSecurityModeAndLevel_t securityModeAndLevel

The desired security mode-level.

uint8_t maxEncryptionKeySize

Maximum LTK size supported by the device.

gapIoCapabilities_t localIoCapabilities

I/O capabilities used to determine the pairing method.

bool_t oobAvailable

TRUE if this device has Out-of-Band data that can be used for authenticated pairing. FALSE otherwise.

gapSmpKeyFlags_t centralKeys

Indicates the SMP keys to be distributed by the Central.

gapSmpKeyFlags_t peripheralKeys

Indicates the SMP keys to be distributed by the Peripheral.

bool_t leSecureConnectionSupported

Indicates if device supports LE Secure Connections pairing. Conflict if this is FALSE and securityModeAndLevel is gSecurityMode_1_Level_4_c.

bool_t useKeypressNotifications

Indicates if device supports Keypress Notification PDUs during Passkey Entry pairing. Conflict if this is TRUE and localIoCapabilities is set to gIoNone_c.

struct gapPeripheralSecurityRequestParameters_t

#include <gap_types.h> Parameters of a Peripheral Security Request.

Public Members

bool_t bondAfterPairing

TRUE if the Peripheral supports bonding.

bool_t authenticationRequired

TRUE if the Peripheral requires authentication for MITM protection.

struct gapAdvertisingParameters_t

#include <gap_types.h> Advertising Parameters; for defaults see gGapDefaultAdvertising-Parameters_d.

Public Members

uint16_t minInterval

Minimum desired advertising interval. Default: 1.28 s.

uint16_t maxInterval

Maximum desired advertising interval. Default: 1.28 s.

bleAdvertisingType_t advertisingType

Advertising type. Default: connectable undirected.

bleAddressType_t ownAddressType

Indicates whether the advertising address is the public address (BD_ADDR) or the random address (set by Gap_SetRandomAddress). Default: public address. If Controller

Privacy is enabled, this parameter is irrelevant as Private Resolvable Addresses are always used.

bleAddressType_t peerAddressType

Address type of the peer; only used in directed advertising and Enhanced Privacy.

bleDeviceAddress_t peerAddress

Address of the peer; same as above.

gapAdvertisingChannelMapFlags_t channelMap

Bit mask indicating which of the three advertising channels are used. Default: all three.

gapAdvertisingFilterPolicy_t filterPolicy

Indicates whether the connect and scan requests are filtered using the Filter Accept List. Default: does not use Filter Accept List (process all).

struct gapExtAdvertisingParameters_tag

#include <gap_types.h> Extended Advertising Parameters; for defaults see gGapDefaultExtAdvertisingParameters_d.

Public Members

uint8_t SID

ID of the advertising set chosen by application. Shall be lower than gBleExtAdvMaxSetId_c

uint8_t handle

ID of the advertising set handled by controller. Shall be lower than gMaxAdvSets_c

uint32_t minInterval

Minimum desired advertising interval. Shall be at least equal or higher than gGapExtAdvertisingIntervalRangeMinimum_c

uint32_t maxInterval

Maximum desired advertising interval. Shall be higher than gGapExtAdvertisingIntervalRangeMinimum_c and higher than minInterval

bleAddressType_t ownAddressType

Indicates whether the advertising address is the public address (BD_ADDR) or the random address (set by Gap_SetRandomAddress). Default: public address. If Controller Privacy is enabled, this parameter is irrelevant as Private Resolvable Addresses are always used.

bleDeviceAddress_t ownRandomAddr

The random address used for advertising on the current handle

bleAddressType_t peerAddressType

Address type of the peer; only used in directed advertising and Enhanced Privacy.

bleDeviceAddress_t peerAddress

Address of the peer; same as above.

gapAdvertisingChannelMapFlags_t channelMap

Bit mask indicating which of the three advertising channels are used for primary advertising

gapAdvertisingFilterPolicy_t filterPolicy

Indicates whether the connect and scan requests are filtered using the Filter Accept List

bleAdvRequestProperties_t extAdvProperties

Type of advertising event

int8_t txPower

The maximum power level at which the adv packets are to be transmitted. The Controller shall choose a power level lower than or equal to the one specified by the Host. Valid range: -127 to 20

gapLePhyMode_t primaryPHY

The PHY on which the advertising packets are transmitted (1M or Coded PHY). Used for sending ADV_EXT_IND

gapLePhyMode_t secondaryPHY

The PHY used for sending AUX_ADV_IND PDU. Used only for Extended Advertising Events

uint8_t secondaryAdvMaxSkip

Maximum number of advertising events that can be skipped before the AUX_ADV_IND can be sent

bool_t enableScanReqNotification

Indicates whether the Controller shall send notifications upon the receipt of a scan request PDU

struct gapExtAdvertisingParametersV2_tag

#include <gap_types.h> Extended Advertising Parameters V2; for defaults see gGapDefaultExtAdvertisingParametersV2_d.

Public Members

uint8_t SID

ID of the advertising set chosen by application. Shall be lower than gBleExtAdvMaxSetId_c

uint8_t handle

ID of the advertising set handled by controller. Shall be lower than gMaxAdvSets_c

uint32_t minInterval

Minimum desired advertising interval. Shall be at least equal or higher than gGapExtAdvertisingIntervalRangeMinimum_c

uint32_t maxInterval

Maximum desired advertising interval. Shall be higher than gGapExtAdvertisingIntervalRangeMinimum_c and higher than minInterval

bleAddressType_t ownAddressType

Indicates whether the advertising address is the public address (BD_ADDR) or the random address (set by Gap_SetRandomAddress). Default: public address. If Controller Privacy is enabled, this parameter is irrelevant as Private Resolvable Addresses are always used.

bleDeviceAddress_t ownRandomAddr

The random address used for advertising on the current handle

bleAddressType_t peerAddressType

Address type of the peer; only used in directed advertising and Enhanced Privacy.

bleDeviceAddress_t peerAddress

Address of the peer; same as above.

gapAdvertisingChannelMapFlags_t channelMap

Bit mask indicating which of the three advertising channels are used for primary advertising

gapAdvertisingFilterPolicy_t filterPolicy

Indicates whether the connect and scan requests are filtered using the Filter Accept List

bleAdvRequestProperties_t extAdvProperties

Type of advertising event

int8_t txPower

The maximum power level at which the adv packets are to be transmitted. The Controller shall choose a power level lower than or equal to the one specified by the Host. Valid range: -127 to 20

gapLePhyMode_t primaryPHY

The PHY on which the advertising packets are transmitted (1M or Coded PHY). Used for sending ADV_EXT_IND

gapLePhyMode_t secondaryPHY

The PHY used for sending AUX_ADV_IND PDU. Used only for Extended Advertising Events

uint8_t secondaryAdvMaxSkip

Maximum number of advertising events that can be skipped before the AUX_ADV_IND can be sent

bool_t enableScanReqNotification

Indicates whether the Controller shall send notifications upon the receipt of a scan request PDU

gapLePhyOptionsFlags_t primaryAdvPhyOptions

Preferred or required coding when transmitting on the primary LE Coded PHY

gapLePhyOptionsFlags_t secondaryAdvPhyOptions

Preferred or required coding when transmitting on the secondary LE Coded PHY

struct gapPeriodicAdvParameters_tag

#include <gap_types.h> Periodic Advertising Parameters; for defaults see gGapDefaultPeriodicAdvParameters_d.

Public Members

uint8_t handle

ID of the advertising set handled by controller. Shall be lower than gMaxAdvSets_c

bool_t addTxPowerInAdv

Set this option to include the Tx power in advertising packet.

uint16_t minInterval

Minimum advertising interval for periodic advertising.

uint16_t maxInterval

Maximum advertising interval for periodic advertising. Should be different and higher than minInterval.

struct gapPeriodicAdvParametersV2_tag

#include <gap_types.h> Periodic Advertising Parameters [v2]

Public Members

uint8_t handle

ID of the advertising set handled by controller. Shall be lower than gMaxAdvSets_c

bool_t addTxPowerInAdv

Set this option to include the Tx power in advertising packet.

uint16_t minInterval

Minimum advertising interval for periodic advertising.

uint16_t maxInterval

Maximum advertising interval for periodic advertising. Should be different and higher than minInterval.

uint8_t numSubevents
: Number of subevents.

uint8_t subeventInterval
: Interval between subevents.

uint8_t responseSlotDelay
: Time between the advertising packet in a subevent and the first response slot.

uint8_t responseSlotSpacing
: Time between response slots.

uint8_t numResponseSlots
: Number of response slots.

struct gapPeriodicAdvSyncTransfer_tag
: *#include <gap_types.h>*

Public Members

deviceId_t deviceId
: Connection identifier

uint16_t serviceData
: Value provided by the host

uint16_t syncHandle
: Identifier for the periodic advertising train

struct gapPeriodicAdvSetInfoTransfer_tag
: *#include <gap_types.h>*

Public Members

deviceId_t deviceId
: Connection identifier

uint16_t serviceData
: Value provided by the host

uint16_t advHandle
: Identifier for the advertising set

struct gapSetPeriodicAdvSyncTransferParams_tag
: *#include <gap_types.h>*

Public Members

deviceId_t deviceId
: Connection identifier

gapPeriodicAdvSyncMode_t mode
: The action to be taken when periodic advertising synchronization information is received

uint16_t skip
: The number of periodic advertising packets that can be skipped after a successful receive

uint16_t syncTimeout
: Synchronization timeout for the periodic advertising train

bleSyncCteType_t CTEType
: 0: Do not sync to packets with an AoA Constant Tone Extension 1: Do not sync to packets with an AoD Constant Tone Extension with 1 us slots 2: Do not sync to packets with an AoD Constant Tone Extension with 2 us slots 4: Do not sync to packets without a Constant Tone Extension

struct gapScanningParameters_t
: *#include <gap_types.h>* Scanning parameters; for defaults see gGapDefaultScanningParameters_d.

Public Members

bleScanType_t type
: Scanning type. Default: passive.

uint16_t interval
: Scanning interval. Default: 10 ms.

uint16_t window
: Scanning window. Default: 10 ms.

bleAddressType_t ownAddressType
: Indicates whether the address used in scan requests is the public address (BD_ADDR) or the random address (set by Gap_SetRandomAddress). Default: public address. If Controller Privacy is enabled, this parameter is irrelevant as Private Resolvable Addresses are always used.

bleScanningFilterPolicy_t filterPolicy
: Indicates whether the advertising packets are filtered using the Filter Accept List. Default: does not use Filter Accept List (scan all).

gapLePhyFlags_t scanningPHYs
: Indicates the PHYs on which the advertising packets should be received on the primary advertising channel.

struct gapCreateSyncReqOptions_tag

#include <gap_types.h> Create Sync Request Options

struct gapPeriodicAdvSyncReq_tag

#include <gap_types.h> Periodic Advertising Sync Request parameters

Public Members

gapCreateSyncReqOptions_t options

Bit 0: Filter Policy. Bit 1: Reporting enabled/disabled. Bit 2: Duplicate filtering disabled/enabled.

uint8_t SID

The SID advertised by the periodic advertiser in the ADI field.

bleAddressType_t peerAddressType

Periodic advertiser's address type (Public or Random)

bleDeviceAddress_t peerAddress

Periodic advertiser's address

uint16_t skipCount

The number of consecutive periodic advertising packets that the receiver may skip after successfully receiving a periodic advertising packet.

uint16_t timeout

The maximum permitted time between successful receives. If this time is exceeded, synchronization is lost.

bleSyncCteType_t cteType

Specifies whether to only sync to certain types of CTE

struct gapConnectionRequestParameters_t

#include <gap_types.h> Connection request parameter structure to be used in the Gap_Connect function; for API-defined defaults, use gGapDefaultConnectionRequestParameters_d.

Public Members

uint16_t scanInterval

Scanning interval. Default: 10 ms.

uint16_t scanWindow

Scanning window. Default: 10 ms.

bleInitiatorFilterPolicy_t filterPolicy

Indicates whether the connection request is issued for a specific device or for all the devices in the Filter Accept List. Default: specific device.

bleAddressType_t ownAddressType

Indicates whether the address used in connection requests is the public address (BD_ADDR) or the random address (set by Gap_SetRandomAddress). Default: public address.

bleAddressType_t peerAddressType

When connecting to a specific device (see filterPolicy), this indicates that device's address type. Default: public address.

bleDeviceAddress_t peerAddress

When connecting to a specific device (see filterPolicy), this indicates that device's address.

uint16_t connIntervalMin

The minimum desired connection interval. Default: 100 ms.

uint16_t connIntervalMax

The maximum desired connection interval. Default: 200 ms.

uint16_t connLatency

The desired connection latency (the maximum number of consecutive connection events the Peripheral is allowed to ignore). Default: 0.

uint16_t supervisionTimeout

The maximum time interval between consecutive over-the-air packets; if this timer expires, the connection is dropped. Default: 10 s.

uint16_t connEventLengthMin

The minimum desired connection event length. Default: 0 ms.

uint16_t connEventLengthMax

The maximum desired connection event length. Default: maximum possible, ~41 s. (lets the Controller decide).

bool_t usePeerIdentityAddress

If Controller Privacy is enabled and this parameter is TRUE, the address defined in the peerAddressType and peerAddress is an identity address. Otherwise, it is a device address.

gapLePhyFlags_t initiatingPHYs

Indicates the PHY on which the advertising packets should be received on the primary advertising channel and the PHY for which connection parameters have been specified.

struct gapConnectionFromPawrParameters_t

#include <gap_types.h> Connection request parameter structure to be used in the Gap_ConnectFromPawr function

Public Members

uint16_t scanInterval

Scanning interval. Default: 10 ms.

uint16_t scanWindow

Scanning window. Default: 10 ms.

bleInitiatorFilterPolicy_t filterPolicy

Indicates whether the connection request is issued for a specific device or for all the devices in the Filter Accept List. Default: specific device.

bleAddressType_t ownAddressType

Indicates whether the address used in connection requests is the public address (BD_ADDR) or the random address (set by Gap_SetRandomAddress). Default: public address.

bleAddressType_t peerAddressType

When connecting to a specific device (see filterPolicy), this indicates that device's address type. Default: public address.

bleDeviceAddress_t peerAddress

When connecting to a specific device (see filterPolicy), this indicates that device's address.

uint16_t connIntervalMin

The minimum desired connection interval. Default: 100 ms.

uint16_t connIntervalMax

The maximum desired connection interval. Default: 200 ms.

uint16_t connLatency

The desired connection latency (the maximum number of consecutive connection events the Peripheral is allowed to ignore). Default: 0.

uint16_t supervisionTimeout

The maximum time interval between consecutive over-the-air packets; if this timer expires, the connection is dropped. Default: 10 s.

uint16_t connEventLengthMin

The minimum desired connection event length. Default: 0 ms.

uint16_t connEventLengthMax

The maximum desired connection event length. Default: maximum possible, ~41 s. (lets the Controller decide).

bool_t usePeerIdentityAddress

If Controller Privacy is enabled and this parameter is TRUE, the address defined in the peerAddressType and peerAddress is an identity address. Otherwise, it is a device address.

gapLePhyFlags_t initiatingPHYs

Indicates the PHY on which the advertising packets should be received on the primary advertising channel and the PHY for which connection parameters have been specified.

uint8_t advHandle

Advertising handle identifying the periodic advertising train.

uint8_t subevent

Subevent where the connection request is to be sent.

struct gapConnectionParameters_t

#include <gap_types.h> Connection parameters as received in the gConnEvtConnected_c connection event.

Public Members

uint16_t connInterval

Interval between connection events.

uint16_t connLatency

Number of consecutive connection events the Peripheral may ignore.

uint16_t supervisionTimeout

The maximum time interval between consecutive over-the-air packets; if this timer expires, the connection is dropped.

bleCentralClockAccuracy_t centralClockAccuracy

Accuracy of central's clock, allowing for frame detection optimizations.

struct gapGenerateDHKeyV2Params_t

#include <gap_types.h> DH Key Generate V2

Public Members

ecdhPublicKey_t remoteP256PublicKey

The remote P-256 public key

gapPrivateKeyType_t keyType

The private key type used for generating the DH key

struct gapConnectionlessCteTransmitParams_t

#include <gap_types.h> Parameter structure to be used in the Gap_SetConnectionlessCteTransmitParameters function.

Public Members

uint8_t handle
: Advertising set handle.

uint8_t cteLength
: Constant Tone Extension length in 8 us.

bleCteType_t cteType
: Type of CTE.

uint8_t cteCount
: Number of CTEs to transmit in each periodic advertising interval.

uint8_t switchingPatternLength
: Number of Antenna IDs in pattern.

uint8_t aAntennaIds[1]
: List of Antenna IDs in pattern.

struct gapConnectionlessIqSamplingParams_t
: *#include <gap_types.h>* Parameter structure to be used in the Gap_EnableConnectionlessIqSampling function.

Public Members

bleIqSamplingEnable_t iqSamplingEnable
: Enable or disable IQ sampling.

bleSlotDurations_t slotDurations
: Switching and sampling slot durations.

uint8_t maxSampledCtes
: Maximum number of CTEs to sample and report in each periodic adv interval.

uint8_t switchingPatternLength
: Number of Antenna IDs in pattern.

uint8_t aAntennaIds[1]
: List of Antenna IDs in pattern.

struct gapConnectionCteTransmitParams_t
: *#include <gap_types.h>* Parameter structure to be used in the Gap_SetConnectionCteTransmitParameters function.

Public Members

bleCteAllowedTypesMap_t cteTypes
Allowed CTE types.

uint8_t switchingPatternLength
Number of Antenna IDs in pattern.

uint8_t aAntennaIds[1]
List of Antenna IDs in pattern.

struct gapConnectionCteReceiveParams_t
#include <gap_types.h> Parameter structure to be used in the Gap_SetConnectionCteReceiveParameters function.

Public Members

bleIqSamplingEnable_t iqSamplingEnable
Enable or disable IQ sampling.

bleSlotDurations_t slotDurations
Switching and sampling slot durations.

uint8_t switchingPatternLength
Number of Antenna IDs in pattern.

uint8_t aAntennaIds[1]
List of Antenna IDs in pattern.

struct gapConnectionCteReqEnableParams_t
#include <gap_types.h> Parameter structure to be used in the Gap_EnableConnectionCteRequest function.

Public Members

bleCteReqEnable_t cteReqEnable
Enable or disable CTE Req procedure.

uint16_t cteReqInterval
Requested interval for initiating CTE Req procedure.

uint8_t requestedCteLength
Minimum length of CTEs requested in 8 us units.

bleCteType_t requestedCteType
Requested types of CTE.

struct gapPathLossReportingParams_t
#include <gap_types.h> Parameter structure to be used in the Gap_SetPathLossReportingParameters function.

Public Members

uint8_t highThreshold

High threshold for the path loss. Units: dB.

uint8_t highHysteresis

Hysteresis value for the high threshold. Units: dB.

uint8_t lowThreshold

Low threshold for the path loss. Units: dB.

uint8_t lowHysteresis

Hysteresis value for the low threshold. Units: dB.

uint16_t minTimeSpent

Minimum time in number of connection events to be observed once the path crosses the threshold before an event is generated.

struct gapAdStructure_t

#include <gap_types.h> Definition of an AD Structure as contained in Advertising and Scan Response packets. An Advertising or Scan Response packet contains several AD Structures.

Public Members

uint8_t length

Total length of the [adType + aData] fields. Equal to 1 + lengthOf(aData).

gapAdType_t adType

AD Type of this AD Structure.

uint8_t *aData

Data contained in this AD Structure; length of this array is equal to (*gapAdStructure_t.length* - 1).

struct gapAdvertisingData_t

#include <gap_types.h> Advertising Data structure : a list of several *gapAdStructure_t* structures.

Public Members

uint8_t cNumAdStructures

Number of AD Structures.

gapAdStructure_t *aAdStructures

Array of AD Structures.

struct gapAdvertisingDecisionData_t

#include <gap_types.h> Extended Advertising Decision Data structure.

Public Members

uint8_t *pKey

Pointer to the key for the resolvable tag. When pKey != NULL Decision data should contain only arbitrary data or pDecisionData should be NULL.

uint8_t *pPrand

Used only when pKey != NULL. When pPrand != NULL it should point the 3 bytes value of the prand. Otherwise it will be generated by the host.

uint8_t *pDecisionData

Pointer to the decision data. When pDecisionData != NULL decision data may contain the resolvable tag and/or arbitrary data.

uint8_t dataLength

The length of the decision data pointed by pDecisionData. When pKey is NULL it should not exceed 8. Otherwise it should not exceed 2

bool_t resolvableTagPresent

When pKey is NULL it indicates whether decision data contains the resolvable tag. In this case the 6 <= dataLength <= 8

struct gapDecisionInstructionsData_tag

#include <gap_types.h>

struct gapSubeventDataStructure_t

#include <gap_types.h> Definition of a Subevent Data structure as contained in Periodic Advertising subevents.

Public Members

uint8_t subevent

Subevent index for this data.

uint8_t responseSlotStart

The first response slots to be used in this subevent.

uint8_t responseSlotCount

The number of response slots to be used.

gapAdvertisingData_t *pAdvertisingData

Advertising data.

struct gapPeriodicAdvertisingSubeventData_t

#include <gap_types.h> Advertising Data structure : a list of several *gapAdStructure_t* structures.

Public Members

uint8_t cNumSubevents
: Number of subevents.

gapSubeventDataStructure_t *aSubeventDataStructures
: Data for each subevent.

struct gapPeriodicAdvertisingResponseData_t
: *#include <gap_types.h>* Periodic Advertising Response data

Public Members

uint16_t requestEvent
: The value of paEventCounter (see [Vol 6] Part B, Section 4.4.2.1) for the periodic advertising packet that the Host is responding to

uint8_t requestSubevent
: The subevent for the periodic advertising packet that the Host is responding to.

uint8_t responseSubevent
: Used to identify the subevent of the PAwR train.

uint8_t responseSlot
: Used to identify the response slot of the PAwR train.

gapAdvertisingData_t *pResponseData
: Response data.

struct gapPeriodicSyncSubeventParameters_t
: *#include <gap_types.h>* Periodic Sync Subevent Parameters

Public Members

uint16_t perAdvProperties
: Bit 6: Include TxPower in the advertising PDU

uint8_t numSubevents
: Number of subevents.

uint8_t aSubevents[1]
: List of subevents

struct gapExtScanNotification_t
: *#include <gap_types.h>*

Public Members

uint8_t handle
Advertising Handle

bleAddressType_t scannerAddrType
Scanner device's address type.

bleDeviceAddress_t aScannerAddr
Scanner device's address.

bool_t scannerAddrResolved
Whether the address corresponds to Resolved Private Address.

struct gapAdvertisingSetTerminated_t
#include <gap_types.h>

Public Members

bleResult_t status
Status of advertising set termination

uint8_t handle
Advertising Handle

deviceId_t deviceId
Valid only if the advertising ended with a connection

uint8_t numCompletedExtAdvEvents
Number of advertising events sent by Controller

struct gapPerAdvSubeventDataRequest_t
#include <gap_types.h>

Public Members

uint8_t handle
Used to identify a periodic advertising train.

uint8_t subeventStart
The first subevent that data is requested for.

uint8_t subeventDataCount
The number of subevents that data is requested for.

struct gapPerAdvResponse_t
#include <gap_types.h>

struct gapAdvertisingEvent_t

#include <gap_types.h> Advertising event structure: type + data.

Public Members

gapAdvertisingEventType_t eventType

Event type.

union *gapAdvertisingEvent_t* eventData

Event data, to be interpreted according to *gapAdvertisingEvent_t.eventType*.

struct gapScannedDevice_t

#include <gap_types.h> Scanned device information structure, obtained from LE Advertising Reports.

Public Members

bleAddressType_t addressType

Device's advertising address type.

bleDeviceAddress_t aAddress

Device's advertising address.

int8_t rssi

RSSI on the advertising channel; may be compared to the TX power contained in the AD Structure of type gAdTxPowerLevel_c to estimate distance from the advertiser.

uint8_t dataLength

Length of the advertising or scan response data.

uint8_t *data

Advertising or scan response data.

bleAdvertisingReportEventType_t advEventType

Advertising report type, indicating what type of event generated this data (advertising, scan response).

bool_t directRpaUsed

TRUE if directed advertising with Resolvable Private Address as Direct Address was detected while Enhanced Privacy is enabled.

bleDeviceAddress_t directRpa

Resolvable Private Address set as Direct Address for directed advertising. Valid only when directRpaUsed is TRUE.

bool_t advertisingAddressResolved

If this is TRUE, the address contained in the addressType and aAddress fields is the identity address of a resolved RPA from the Advertising Address field. Otherwise, the address from the respective fields is the public or random device address contained in the Advertising Address field.

struct gapExtScannedDevice_t

#include <gap_types.h>

Public Members

bleAddressType_t addressType

Device's advertising address type.

bleDeviceAddress_t aAddress

Device's advertising address.

uint8_t SID

Advertising set id

bool_t advertisingAddressResolved

If this is TRUE, the address contained in the addressType and aAddress fields is the identity address of a resolved RPA from the Advertising Address field. Otherwise, the address from the respective fields is the public or random device address contained in the Advertising Address field.

bleAdvReportEventProperties_t advEventProperties

Advertising report properties, indicating what type of event generated this data (advertising, scan response).

int8_t rssi

RSSI on the advertising channel; may be compared to the TX power contained in the AD Structure of type gAdTxPowerLevel_c to estimate distance from the advertiser.

int8_t txPower

The Tx power level of the advertiser

uint8_t primaryPHY

Advertiser PHY for primary channel

uint8_t secondaryPHY

Advertiser PHY for secondary channel

uint16_t periodicAdvInterval

Interval of the periodic advertising. Zero if not periodic advertising.

bool_t directRpaUsed

TRUE if directed advertising with Resolvable Private Address as Direct Address was detected while Enhanced Privacy is enabled.

bleAddressType_t directRpaType

Address type for directed advertising. Valid only when directRpaUsed is TRUE.

bleDeviceAddress_t directRpa

Resolvable Private Address set as Direct Address for directed advertising. Valid only when directRpaUsed is TRUE.

uint16_t dataLength

Length of the advertising or scan response data.

uint8_t *pData

Advertising or scan response data.

struct gapPeriodicScannedDevice_t

#include <gap_types.h>

Public Members

uint16_t syncHandle

Sync Handle

int8_t txPower

The Tx power level of the advertiser

int8_t rssi

RSSI on the advertising channel; may be compared to the TX power contained in the AD Structure of type gAdTxPowerLevel_c to estimate distance from the advertiser.

bleCteType_t cteType

Type of Constant Tone Extension in the periodic advertising packets.

uint16_t dataLength

Length of the advertising or scan response data.

uint8_t *pData

Advertising or scan response data.

struct gapPeriodicScannedDeviceV2_t

#include <gap_types.h>

Public Members

uint16_t syncHandle

Sync Handle

int8_t txPower

The Tx power level of the advertiser

int8_t rssi

RSSI on the advertising channel; may be compared to the TX power contained in the AD Structure of type gAdTxPowerLevel_c to estimate distance from the advertiser.

bleCteType_t cteType

Type of Constant Tone Extension in the periodic advertising packets.

uint16_t periodicEventCounter

The value of paEventCounter (see [Vol 6] Part B, Section 4.4.2.1) for the reported periodic advertising packet.

uint8_t subevent

Subevent number.

uint16_t dataLength

Length of the advertising or scan response data.

uint8_t *pData

Advertising or scan response data.

struct gapSyncEstbEventData_t

#include <gap_types.h>

Public Members

bleResult_t status

Status of the Sync Established Event

uint16_t syncHandle

Sync Handle

uint8_t SID

Value of the Advertising SID subfield in the ADI field of the PDU

bleAddressType_t peerAddressType

Advertiser Address Type

bleDeviceAddress_t peerAddress

Advertiser Address

gapLePhyMode_t PHY

Advertiser PHY

uint16_t periodicAdvInterval

Periodic advertising interval

bleAdvertiserClockAccuracy_t advertiserClockAccuracy

Advertiser Clock Accuracy

uint8_t numSubevents
: Only relevant for v2 of the event, otherwise value is 0

uint8_t subeventInterval
: Only relevant for v2 of the event, otherwise value is 0

uint8_t responseSlotDelay
: Only relevant for v2 of the event, otherwise value is 0

uint8_t responseSlotSpacing
: Only relevant for v2 of the event, otherwise value is 0

struct gapSyncLostEventData_t
: *#include <gap_types.h>*

Public Members

uint16_t syncHandle
: Sync Handle

struct gapConnectionlessIqReport_t
: *#include <gap_types.h>*

Public Members

uint16_t syncHandle
: Sync Handle.

uint8_t channelIndex
: Index of the channel on which the packet was received.

int16_t rssi
: RSSI of the packet.

uint8_t rssiAntennaId
: Antenna ID.

bleCteType_t cteType
: Type of CTE on the received packet (AoA, AoD 1 us, AoD 2 us).

bleSlotDurations_t slotDurations
: Durations of switching/sampling slots.

bleIqReportPacketStatus_t packetStatus
: Packet status, information about CRC.

uint16_t periodicEventCounter

The value of paEventCounter for the reported AUX_SYNC_IND PDU.

uint8_t sampleCount

Total number of sample pairs.

int8_t *aI_samples

List of sampleCount I_samples.

int8_t *aQ_samples

List of sampleCount Q_samples.

struct gapScanningEvent_t

#include <gap_types.h> Scanning event structure: type + data.

Public Members

gapScanningEventType_t eventType

Event type.

union *gapScanningEvent_t* eventData

Event data, to be interpreted according to *gapScanningEvent_t.eventType*.

struct gapConnectedEvent_t

#include <gap_types.h> Event data structure for the gConnEvtConnected_c event.

Public Members

gapConnectionParameters_t connParameters

Connection parameters established by the Controller.

bleAddressType_t peerAddressType

Connected device's address type.

bleDeviceAddress_t peerAddress

Connected device's address.

bool_t peerRpaResolved

If this is TRUE, the address defined by peerAddressType and peerAddress is the identity address of the peer, and the peer used an RPA that was resolved by the Controller and is contained in the peerRpa field. Otherwise, it is a device address. This parameter is irrelevant if Controller Privacy is not enabled.

bleDeviceAddress_t peerRpa

Peer Resolvable Private Address if Controller Privacy is active and peerRpaResolved is TRUE.

bool_t localRpaUsed

If this is TRUE, the Controller has used an RPA contained in the localRpa field. This parameter is irrelevant if Controller Privacy is not enabled.

bleDeviceAddress_t localRpa

Local Resolvable Private Address if Controller Privacy is active and localRpaUsed is TRUE.

bleLlConnectionRole_t connectionRole

Connection Role - central or peripheral.

uint8_t advHandle

Only relevant if the connection was from PAWR.

uint16_t syncHandle

Only relevant if the connection was from PAWR.

struct gapKeyExchangeRequestEvent_t

#include <gap_types.h> Event data structure for the gConnEvtKeyExchangeRequest_c event.

Public Members

gapSmpKeyFlags_t requestedKeys

Mask identifying the keys being requested.

uint8_t requestedLtkSize

Requested size of the encryption key.

struct gapKeysReceivedEvent_t

#include <gap_types.h> Event data structure for the gConnEvtKeysReceived_c event.

Public Members

gapSmpKeys_t *pKeys

The SMP keys distributed by the peer.

struct gapAuthenticationRejectedEvent_t

#include <gap_types.h> Event data structure for the gConnEvtAuthenticationRejected_c event.

Public Members

gapAuthenticationRejectReason_t rejectReason

Peripheral's reason for rejecting the authentication.

struct gapPairingCompleteEvent_t

#include <gap_types.h> Event data structure for the gConnEvtPairingComplete_c event.

Public Members

bool_t pairingSuccessful

TRUE if pairing succeeded, FALSE otherwise.

union *gapPairingCompleteEvent_t* pairingCompleteData

Information of completion, selected upon the value of *gapPairingCompleteEvent_t.pairingSuccessful*.

struct gapLongTermKeyRequestEvent_t

#include <gap_types.h> Event data structure for the gConnEvtLongTermKeyRequest_c event.

Public Members

uint16_t ediv

The Encryption Diversifier, as defined by the SMP.

uint8_t aRand[(8U)]

The Random number, as defined by the SMP.

uint8_t randSize

Usually equal to gcMaxRandSize_d.

struct gapEncryptionChangedEvent_t

#include <gap_types.h> Event data structure for the gConnEvtEncryptionChanged_c event.

Public Members

bool_t newEncryptionState

TRUE if link has been encrypted, FALSE if encryption was paused or removed.

struct gapDisconnectedEvent_t

#include <gap_types.h> Event data structure for the gConnEvtDisconnected_c event.

Public Members

gapDisconnectionReason_t reason

Reason for disconnection.

struct gapConnParamsUpdateReq_t

#include <gap_types.h> Event data structure for the gConnEvtParameterUpdateRequest_c event.

Public Members

uint16_t intervalMin

Minimum interval between connection events.

uint16_t intervalMax

Maximum interval between connection events.

uint16_t peripheralLatency

Number of consecutive connection events the Peripheral may ignore.

uint16_t timeoutMultiplier

The maximum time interval between consecutive over-the-air packets; if this timer expires, the connection is dropped.

struct gapConnParamsUpdateComplete_t

#include <gap_types.h> Event data structure for the gConnEvtParameterUpdateComplete_c event.

Public Members

uint16_t connInterval

Interval between connection events.

uint16_t connLatency

Number of consecutive connection events the Peripheral may ignore.

uint16_t supervisionTimeout

The maximum time interval between consecutive over-the-air packets; if this timer expires, the connection is dropped.

struct gapConnLeDataLengthChanged_t

#include <gap_types.h> Event data structure for the gConnEvtLeDataLengthChanged_c event.

Public Members

uint16_t maxTxOctets

The maximum number of payload octets in a Link Layer Data Channel PDU to transmit on this connection.

uint16_t maxTxTime

The maximum time that the local Controller will take to send a Link Layer Data Channel PDU on this connection.

uint16_t maxRxOctets

The maximum number of payload octets in a Link Layer Data Channel PDU to receive on this connection.

uint16_t maxRxTime

The maximum time that the local Controller will take to receive a Link Layer Data Channel PDU on this connection.

struct gapConnIqReport_t

#include <gap_types.h> Event data structure for the gConnEvtIqReportReceived_c event.

Public Members

gapLePhyMode_t rxPhy

Identifies receiver PHY for this connection.

uint8_t dataChannelIndex

Index of the data channel on which the Data Physical Channel PDU was received.

int16_t rssi

RSSI of the packet.

uint8_t rssiAntennaId

Antenna ID.

bleCteType_t cteType

Type of CTE on the received packet (AoA, AoD 1 us, AoD 2 us).

bleSlotDurations_t slotDurations

Durations of switching/sampling slots.

bleIqReportPacketStatus_t packetStatus

Packet status, information about CRC.

uint16_t connEventCounter

The value of the connEventCounter for the reported PDU.

uint8_t sampleCount

Total number of sample pairs.

int8_t *aI_samples

List of sampleCount I_samples

int8_t *aQ_samples

List of sampleCount Q_samples

struct gapConnCteRequestFailed_t

#include <gap_types.h> Event data structure for the gConnEvtCteRequestFailed_c event.

Public Members

bleResult_t status

Status (0x00 - received response but without CTE, 0x01-0xFF - peer rejected request

struct gapPathLossThresholdEvent_t

#include <gap_types.h> Event data structure for the gConnEvtPathLossThreshold_c event.

Public Members

uint8_t currentPathLoss

Current path loss. Units: dB.

blePathLossThresholdZoneEntered_t zoneEntered

Low, middle or high.

struct gapTransmitPowerReporting_t

#include <gap_types.h> Event data structure for the gConnEvtTransmitPowerReporting_c event.

Public Members

bleTxPowerReportingReason_t reason

Reason for generating this event

- local tx power changed
- remote tx power changed
- a HCI_LE_Read_Remote_Transmit_Power_Level command completed

blePowerControlPhyType_t phy

The PHY for which the event is generated.

int8_t txPowerLevel

New transmit power level on this connection and PHY.

bleTxPowerLevelFlags_t flags

Tx power level flags.

int8_t delta

Change in tx power level. Units: dB.

struct gapTransmitPowerInfo_t

#include <gap_types.h> Event data structure for the gConnEvtEnhancedReadTransmitPowerLevel_c event.

Public Members

blePowerControlPhyType_t phy
The PHY for which the event is generated.

int8_t currTxPowerLevel
Current tx power level on this connection and PHY.

int8_t maxTxPowerLevel
Maximum tx power level on this connection and PHY.

struct gapEattConnectionRequest_t
#include <gap_types.h> Event data structure for the gConnEvtEattConnectionRequest_c event.

struct gapEattConnectionComplete_t
#include <gap_types.h> Event data structure for the gConnEvtEattConnectionComplete_c event.

struct gapEattReconfigureResponse_t
#include <gap_types.h> Event data structure for the gConnEvtEattChannelReconfigureResponse_c event.

struct gapEattBearerStatusNotification_t
#include <gap_types.h> Event data structure for the bearer status update event.

struct gapHandoverConnectedEvent_t
#include <gap_types.h> Event data structure for the gConnEvtHandoverConnected_c event.

Public Members

bleAddressType_t peerAddressType
Connected device's address type.

bleDeviceAddress_t peerAddress
Connected device's address.

bleLlConnectionRole_t connectionRole
Connection Role - master or slave.

struct gapHandoverDisconnectedEvent_t
#include <gap_types.h> Event data structure for the gHandoverDisconnected_c event.

Public Members

bleResult_t status
Status for the handover disconnect command

struct gapConnectionEvent_t

#include <gap_types.h> Connection event structure: type + data.

Public Members

gapConnectionEventType_t eventType

Event type

union *gapConnectionEvent_t* eventData

Event data, to be interpreted according to *gapConnectionEvent_t.eventType*.

struct gapIdentityInformation_t

#include <gap_types.h> Identity Information structure definition

Public Members

bleIdentityAddress_t identityAddress

Identity Address - Public or Random Static

uint8_t irk[(16U)]

Identity Resolving Key - must not be all-zero if Network Privacy is used

blePrivacyMode_t privacyMode

Privacy mode to be used for the entry on the resolving list

struct gapAutoConnectParams_t

#include <gap_types.h> Parameters for the Auto Connect Scan Mode.

Public Members

uint8_t cNumAddresses

Number of device addresses to automatically connect to.

bool_t writeInFilterAcceptList

If set to TRUE, the device addresses are written in the Filter Accept List before scanning is enabled.

gapConnectionRequestParameters_t *aAutoConnectData

The array of connection request parameters, of size equal to cNumAddresses.

struct gapHostVersion_tag

#include <gap_types.h>

union testParameters

Public Members

uint8_t resolvableTagKey[(16U)]

struct *gapDecisionInstructionsData_tag* arbitraryData

struct *gapDecisionInstructionsData_tag* rssi

struct *gapDecisionInstructionsData_tag* pathLoss

struct *gapDecisionInstructionsData_tag* advA

gapDecisionInstructionsAdvMode_t advMode

struct arbitraryData

struct rssi

struct pathLoss

struct advA

union eventData

Public Members

bleResult_t failReason

Event data for gAdvertisingCommandFailed_c event type: reason of failure to enable or disable advertising.

gapExtScanNotification_t scanNotification

Event data for gExtScanNotification_c event type: Scan Request Received Event.

gapAdvertisingSetTerminated_t advSetTerminated

Event received when advertising in a given advertising set has stopped.

gapPerAdvSubeventDataRequest_t subeventDataRequest

Event received when doing PAWR.

gapPerAdvResponse_t perAdvResponse

Periodic Advertising Response.

uint8_t advHandle

Event data for gExtAdvertisingStateChanged_c event type.

union eventData

Public Members

bleResult_t failReason

Event data for gScanCommandFailed_c or gPeriodicAdvSyncEstablished_c event type: reason of failure to enable/disable scanning or to establish sync.

gapScannedDevice_t scannedDevice

Event data for gDeviceScanned_c event type: scanned device information.

gapExtScannedDevice_t extScannedDevice

Event data for gExtDeviceScanned_c event type: extended scanned device information.

gapPeriodicScannedDevice_t periodicScannedDevice

Event data for gPeriodicDeviceScanned_c event type.

gapPeriodicScannedDeviceV2_t periodicScannedDeviceV2

Event data for gPeriodicDeviceScannedV2_c event type.

gapSyncEstbEventData_t syncEstb

Event data for gPeriodicAdvSyncEstablished_c event type: Sync handle information for the application.

gapSyncLostEventData_t syncLost

Event data for gPeriodicAdvSyncLost_c event type: Sync handle information for the application.

gapConnectionlessIqReport_t iqReport

Event data for gConnectionlessIqReportReceived_c event type: IQ information for the application.

union pairingCompleteData

Public Members

bool_t withBonding

If pairingSuccessful is TRUE, this indicates whether the devices bonded.

bleResult_t failReason

If pairingSuccessful is FALSE, this contains the reason of failure.

union eventData

Public Members

gapConnectedEvent_t connectedEvent

Data for gConnEvtConnected_c: information about the connection parameters.

gapPairingParameters_t pairingEvent

Data for gConnEvtPairingRequest_c, gConnEvtPairingResponse_c: pairing parameters.

gapAuthenticationRejectedEvent_t authenticationRejectedEvent

Data for gConnEvtAuthenticationRejected_c: reason for rejection.

gapPeripheralSecurityRequestParameters_t peripheralSecurityRequestEvent

Data for gConnEvtPeripheralSecurityRequest_c: Peripheral's security requirements.

gapKeyExchangeRequestEvent_t keyExchangeRequestEvent

Data for gConnEvtKeyExchangeRequest_c: mask indicating the keys that were requested by the peer.

gapKeysReceivedEvent_t keysReceivedEvent

Data for gConnEvtKeysReceived_c: the keys received from the peer.

gapPairingCompleteEvent_t pairingCompleteEvent

Data for gConnEvtPairingComplete_c: fail reason or (if successful) bonding state.

gapLongTermKeyRequestEvent_t longTermKeyRequestEvent

Data for gConnEvtLongTermKeyRequest_c: encryption diversifier and random number.

gapEncryptionChangedEvent_t encryptionChangedEvent

Data for gConnEvtEncryptionChanged_c: new encryption state.

gapDisconnectedEvent_t disconnectedEvent

Data for gConnEvtDisconnected_c: reason for disconnection.

int8_t rssi_dBm

Data for gConnEvtRssiRead_c: value of the RSSI in dBm.

int8_t txPowerLevel_dBm

Data for gConnEvtTxPowerLevelRead_c: value of the TX power.

bleResult_t failReason

Data for gConnEvtPowerReadFailure_c: reason for power reading failure.

uint32_t passkeyForDisplay

gapConnParamsUpdateReq_t connectionUpdateRequest

Data for gConnEvtParameterUpdateRequest_c: connection parameters update.

gapConnParamsUpdateComplete_t connectionUpdateComplete

Data for gConnEvtParameterUpdateComplete_c: connection parameters update.

gapConnLeDataLengthChanged_t leDataLengthChanged

Data for gConnEvtLeDataLengthChanged_c: new data length parameters

gapKeypressNotification_t incomingKeypressNotification

uint32_t numericValueForDisplay

bleChannelMap_t channelMap

Data for gConnEvtChannelMapRead_c: channel map read from the Controller

gapConnIqReport_t connIqReport

Data for gConnEvtIqReportReceived_c: IQ information received from a peer

gapConnCteRequestFailed_t cteRequestFailedEvent

Data for gConnEvtCteRequestFailed_c: CTE Request to peer has failed

bleResult_t perAdvSyncTransferStatus

gapPathLossThresholdEvent_t pathLossThreshold

Data for gConnEvtPathLossThreshold_c: current path loss and zone entered.

gapTransmitPowerReporting_t transmitPowerReporting

Data for gConnEvtTransmitPowerReporting_c: changes in power levels.

gapTransmitPowerInfo_t transmitPowerInfo

Data for gConnEvtEnhancedReadTransmitPowerLevel_c: local power level information.

gapEattConnectionRequest_t eattConnectionRequest

Data for gConnEvtEattConnectionRequest_c: notification of L2Cap Enhanced Connect request for EATT.

gapEattConnectionComplete_t eattConnectionComplete

Data for gConnEvtEattConnectionComplete_c: result of *Gap_EattConnectionRequest()*.

gapEattReconfigureResponse_t eattReconfigureResponse

Data for gConnEvtEattChannelReconfigureResponse_c: result of *Gap_EattReconfigureRequest()*.

gapEattBearerStatusNotification_t eattBearerStatusNotification

Data for gConnEvtEattBearerStatusNotification_c: bearer status update.

gapHandoverConnectedEvent_t handoverConnectedEvent

Data for gConnEvtHandoverConnected_c: information about the connection parameters.

gapHandoverDisconnectedEvent_t handoverDisconnectedEvent

Data for gHandoverDisconnected_c: status of the Gap_HandoverDisconnect.

bleResult_t smError

Data for gConnEvtSmError_c: SM error status.

GATT

enum attErrorCode_t

ATT error codes

Values:

enumerator gAttErrCodeNoError_c

No error has occured.

enumerator gAttErrCodeInvalidHandle_c

The attribute handle given was not valid on this server.

enumerator gAttErrCodeReadNotPermitted_c

The attribute cannot be read.

enumerator gAttErrCodeWriteNotPermitted_c

The attribute cannot be written.

enumerator gAttErrCodeInvalidPdu_c

The attribute PDU was invalid.

enumerator gAttErrCodeInsufficientAuthentication_c

The attribute requires authentication before it can be read or written.

enumerator gAttErrCodeRequestNotSupported_c

ATT Server does not support the request received from the client.

enumerator gAttErrCodeInvalidOffset_c

Offset specified was past the end of the attribute.

enumerator gAttErrCodeInsufficientAuthorization_c

The attribute requires authorization before it can be read or written.

enumerator gAttErrCodePrepareQueueFull_c

Too many prepare writes have been queued.

enumerator gAttErrCodeAttributeNotFound_c

No attribute found within the given attribute handle range.

enumerator gAttErrCodeAttributeNotLong_c

The attribute cannot be read using the ATT_READ_BLOB_REQ PDU.

enumerator gAttErrCodeInsufficientEncryptionKeySize_c

The Encryption Key Size used for encrypting this link is too short.

enumerator gAttErrCodeInvalidAttributeValueLength_c

The attribute value length is invalid for the operation.

enumerator gAttErrCodeUnlikelyError_c

The attribute request could not be completed due to an unlikely error.

enumerator gAttErrCodeInsufficientEncryption_c

The attribute requires encryption before it can be read or written.

enumerator gAttErrCodeUnsupportedGroupType_c

The attribute type is not a supported grouping attribute.

enumerator gAttErrCodeInsufficientResources_c

Insufficient Resources to complete the request.

enumerator gAttErrCodeDatabaseOutOfSync_c

The server requests the client to rediscover the database.

enumerator gAttErrCodeValueNotAllowed_c

The attribute parameter value was not allowed.

enumerator gAttErrCodeWriteRequestRejected_c

Write request cannot be fulfilled for reasons other than permissions.

enumerator gAttErrCodeCccdImproperlyConfigured_c

CCCD is not configured according to the requirements of the profile or service.

enumerator gAttErrCodeProcedureAlreadyInProgress_c

Profile or service request cannot be serviced because another operation is still in progress.

enumerator gAttErrCodeOutOfRange_c

Attribute value is out of range as defined by a profile or service specification.

enum gattCachingClientState_c

GATT Caching Client states

Values:

enumerator gGattClientChangeUnaware_c

Gatt client is “change-unaware” regarding changes in the database definitions on the Server.

enumerator gGattClientStateChangePending_c

Gatt client is in the process of going from “change-unaware” to “change-aware”.

enumerator gGattClientChangeAware_c

Gatt client is “change-aware” regarding the database definitions on the Server.

enum gattClientHashUpdateType_t

Hash Update type

Values:

enumerator gattClientFirstConnection_c

Hash update for the first connection with a peer

enumerator gattClientReconnectBondedPeer_c
Hash update after reconnecting with a bonded peer

enumerator gattClientActiveConnectionUpdate
Hash update when a change occurs during an active connection

enumerator gattClientNoChange
Idle state - no change

enum gattProcedureType_t
GATT Client Procedure type
Values:

enumerator gGattProcExchangeMtu_c
MTU Exchange

enumerator gGattProcDiscoverAllPrimaryServices_c
Primary Service Discovery

enumerator gGattProcDiscoverPrimaryServicesByUuid_c
Discovery of Services by UUID

enumerator gGattProcFindIncludedServices_c
Discovery of Included Services within a Service range

enumerator gGattProcDiscoverAllCharacteristics_c
Characteristic Discovery within Service range

enumerator gGattProcDiscoverCharacteristicByUuid_c
Characteristic Discovery by UUID

enumerator gGattProcDiscoverAllCharacteristicDescriptors_c
Characteristic Descriptor Discovery

enumerator gGattProcReadCharacteristicValue_c
Characteristic Reading using Value handle

enumerator gGattProcReadUsingCharacteristicUuid_c
Characteristic Reading by UUID

enumerator gGattProcReadMultipleCharacteristicValues_c
Reading multiple Characteristics at once

enumerator gGattProcWriteCharacteristicValue_c
Characteristic Writing

enumerator gGattProcReadCharacteristicDescriptor_c
Reading Characteristic Descriptors

enumerator gGattProcWriteCharacteristicDescriptor_c
Writing Characteristic Descriptors

enumerator gGattProcReadMultipleVarLengthCharValues_c
Read Multiple Variable Length Characteristic Values

enum gattProcedurePhase_t
GATT Procedure phase

Values:

enumerator gattProcPhaseInitiated
GATT procedure has been initiated.

enumerator gattProcPhaseRunning
GATT procedure is running.

typedef struct *gattService_tag* gattService_t
GATT Service structure definition

typedef uint8_t gattCccdFlags_t
Flags for the value of the Client Characteristic Configuration Descriptor.

bleResult_t Gatt_Init(void)
Initializes the GATT module.

Remark

If the GAP module is present, this function is called internally by *Ble_HostInitialize()*. Otherwise, the application must call this function once at device start-up.

Remark

This function executes synchronously.

Return values
gBleSuccess_c –

bleResult_t Gatt_GetMtu(*deviceId_t* deviceId, uint16_t *pOutMtu)
Retrieves the MTU used with a given connected device.

Remark

This function executes synchronously.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- pOutMtu – **[out]** Pointer to integer to be written.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.

gCccdEmpty_c
: Nothing is enabled.

gCccdNotification_c
: Enables notifications.

gCccdIndication_c
: Enabled indications.

struct gattAttribute_t
: *#include <gatt_types.h>* GATT Attribute structure definition

Public Members

uint16_t handle
: Attribute handle.

bleUuidType_t uuidType
: Type of the UUID.

bleUuid_t uuid
: The attribute's UUID.

uint16_t valueLength
: Length of the attribute value array.

uint16_t maxValueLength
: Maximum length of the attribute value array; if this is set to 0, then the attribute's length is fixed and cannot be changed.

uint8_t *paValue
: Attribute value array.

struct gattCharacteristic_t
: *#include <gatt_types.h>* GATT Characteristic structure definition

Public Members

gattCharacteristicPropertiesBitFields_t properties
: Characteristic Properties as defined by GATT.

gattAttribute_t value
: Characteristic Value attribute.

uint8_t cNumDescriptors

Size of the Characteristic Descriptors array.

gattAttribute_t *aDescriptors

Characteristic Descriptors array.

struct gattService_tag

#include <gatt_types.h> GATT Service structure definition

Public Members

uint16_t startHandle

The handle of the Service Declaration attribute.

uint16_t endHandle

The last handle belonging to this Service (followed by another Service declaration of the end of the database).

bleUuidType_t uuidType

Service UUID type.

bleUuid_t uuid

Service UUID.

uint8_t cNumCharacteristics

Size of the Characteristic array.

gattCharacteristic_t *aCharacteristics

Characteristic array.

uint8_t cNumIncludedServices

Size of the Included Services array.

struct *gattService_tag* *aIncludedServices

Included Services array.

struct gattDbCharPresFormat_t

#include <gatt_types.h> Characteristic Presentation Format Descriptor structure

Public Members

uint8_t format

Format of the value of this characteristic.

int8_t exponent

Exponent field to determine how the value of this characteristic is further formatted.

uint16_t unitUuid16
: The unit of this characteristic.

uint8_t ns
: The name space of the description.

uint16_t description
: The description of this characteristic.

struct gattHandleRange_t
: *#include <gatt_types.h>* GATT Handle Range structure definition

Public Members

uint16_t startHandle
: Start Handle.

uint16_t endHandle
: End Handle - shall be greater than or equal to Start Handle.

struct procStatus_t
: *#include <gatt_types.h>* GATT Procedure Status structure definition

Public Members

bool_t isOngoing
: Indicates whether the GATT procedure type is ongoing.

gattProcedureType_t ongoingProcedureType
: Procedure type.

gattProcedurePhase_t ongoingProcedurePhase
: Procedure phase.

struct procDataStruct_t
: *#include <gatt_types.h>* GATT Procedure Data structure definition. Structure members are ordered to minimize the padding size

Public Members

uint16_t index
: Number of entries currently stored.

uint16_t max
: Maximum number of entries to store.

bleUuid_t charUuid
: UUID of the characteristic to be discovered.

bleUuidType_t charUuidType
: UUID type of the characteristic to be discovered.

bool_t reliableLongWrite
: Indicates whether to do reliable long writes.

bool_t bAllocatedArray
: Indicates whether the array is allocated.

union *procDataStruct_t* pOutActualCount
: Pointer to the memory locatio where to store the final number of added entries.

union *procDataStruct_t* array
: Array where data is stored.

union *procDataStruct_t* reqParams
: Parameters of the GATT procedure

union pOutActualCount

Public Members

uint8_t *pCount8b
: Pointer to a uint8_t memory location where to store the final number of added entries.

uint16_t *pCount16b
: Pointer to a uint16_t memory location where to store the final number of added entries.

union array

Public Members

gattService_t *aServices
: Array of services.

gattCharacteristic_t *aChars
: Array of characteristics.

gattAttribute_t *aDescriptors
: Array of descriptors.

uint8_t *aBytes
: Array of bytes.

uint16_t *aHandles
Array of handles.

union reqParams

Public Members

attReadByGroupTypeRequestParams_t rbgtParams
Read By Group Type Request Parameters.

attFindByTypeValueRequestParams_t fbtvParams
Find By Type Value Request Parameters.

attReadByTypeRequestParams_t rbtParams
Read By Type Request Parameters.

attFindInformationRequestParams_t fiParams
Find Information Request Parameters.

attReadRequestParams_t rParams
Read Request Parameters.

attReadBlobRequestParams_t rbParams
Read Blob Request Parameters.

attReadMultipleRequestParams_t rmParams
Read Multiple Request Parameters.

attVarWriteRequestAndCommandParams_t wParams
Write Request and Write Command Parameters for variable value length.

attSignedWriteCommandParams_t swParams
Signed Write Command parameters.

attPrepareWriteRequestResponseParams_t pwParams
Prepare Write Request and Prepare Write Response Parameters.

attExecuteWriteRequestParams_t ewParams
Execute Write Request Parameters

GATT Client

enum gattProcedureResult_t
GATT Client Procedure Result type
Values:

enumerator gGattProcSuccess_c

The procedure was completed successfully.

enumerator gGattProcError_c

The procedure was terminated due to an error.

typedef void (*gattClientProcedureCallback_t)(*deviceId_t* deviceId, *gattProcedureType_t* procedureType, *gattProcedureResult_t* procedureResult, *bleResult_t* error)

GATT Client Procedure Callback type

typedef void (*gattClientNotificationCallback_t)(*deviceId_t* deviceId, uint16_t characteristicValueHandle, uint8_t *aValue, uint16_t valueLength)

GATT Client Notification Callback prototype

typedef *gattClientNotificationCallback_t* gattClientIndicationCallback_t

GATT Client Indication Callback prototype

typedef void (*gattClientMultipleValueNotificationCallback_t)(*deviceId_t* deviceId, uint8_t *aHandleLenValue, uint32_t totalLength)

GATT Client Multiple Value Notification Callback prototype

typedef void (*gattClientEnhancedProcedureCallback_t)(*deviceId_t* deviceId, *bearerId_t* bearerId, *gattProcedureType_t* procedureType, *gattProcedureResult_t* procedureResult, *bleResult_t* error)

GATT Client Enhanced Procedure Callback type

typedef void (*gattClientEnhancedNotificationCallback_t)(*deviceId_t* deviceId, *bearerId_t* bearerId, uint16_t characteristicValueHandle, uint8_t *aValue, uint16_t valueLength)

GATT Client Enhanced Notification Callback prototype

typedef *gattClientEnhancedNotificationCallback_t* gattClientEnhancedIndicationCallback_t

GATT Client Enhanced Indication Callback prototype

typedef void (*gattClientEnhancedMultipleValueNotificationCallback_t)(*deviceId_t* deviceId, *bearerId_t* bearerId, uint8_t *aHandleLenValue, uint32_t totalLength)

GATT Client Enhanced Multiple Value Notification Callback prototype

procDataStruct_t *pProcedureData[]

bleResult_t GattClient_Init(void)

Initializes the GATT Client functionality.

Remark

This should be called once at device startup, if necessary.

Remark

This function executes synchronously.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_ResetProcedure(void)

Resets any ongoing GATT Client Procedure.

Remark

This function should be called if an ongoing Client procedure needs to be stopped.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_RegisterProcedureCallback(*gattClientProcedureCallback_t* callback)

Installs the application callback for the GATT Client module Procedures.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_RegisterNotificationCallback(*gattClientNotificationCallback_t* callback)

Installs the application callback for Server Notifications.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_RegisterIndicationCallback(*gattClientIndicationCallback_t* callback)

Installs the application callback for Server Indications.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_RegisterMultipleValueNotificationCallback(*gattClientMultipleValueNotificationCallback_t* callback)

Installs the application callback for Server Multiple Value Notification.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_ExchangeMtu(*deviceId_t* deviceId, uint16_t mtu)

Initializes the MTU Exchange procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- mtu – **[in]** Desired MTU size.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.

- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_DiscoverAllPrimaryServices(*deviceId_t* deviceId, *gattService_t* *aOutPrimaryServices, uint8_t maxServiceCount, uint8_t *pOutDiscoveredCount)

Initializes the Primary Service Discovery procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- aOutPrimaryServices – **[out]** Statically allocated array of gattService_t. The GATT module fills each Service's handle range and UUID.
- maxServiceCount – **[in]** Maximum number of services to be filled.
- pOutDiscoveredCount – **[out]** The actual number of services discovered.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_DiscoverPrimaryServicesByUuid(*deviceId_t* deviceId, *bleUuidType_t* uuidType, const *bleUuid_t* *pUuid, *gattService_t* *aOutPrimaryServices, uint8_t maxServiceCount, uint8_t *pOutDiscoveredCount)

Initializes the Primary Service Discovery By UUID procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- uuidType – **[in]** Service UUID type.
- pUuid – **[in]** Service UUID.

- aOutPrimaryServices – **[out]** Statically allocated array of gattService_t. The GATT module fills each Service's handle range.
- maxServiceCount – **[in]** Maximum number of services to be filled.
- pOutDiscoveredCount – **[out]** The actual number of services discovered.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_FindIncludedServices(*deviceId_t* deviceId, *gattService_t* *pIoService, uint8_t maxServiceCount)

Initializes the Find Included Services procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- pIoService – **[inout]** The service within which inclusions should be searched. The GATT module uses the Service's handle range and fills the included Services' handle ranges, UUID types and the UUIDs if they are 16-bit UUIDs.
- maxServiceCount – **[in]** Maximum number of included services to be filled.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_DiscoverAllCharacteristicsOfService(*deviceId_t* deviceId, *gattService_t* *pIoService, uint8_t maxCharacteristicCount)

Initializes the Characteristic Discovery procedure for a given Service.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- pIoService – **[inout]** The service within which characteristics should be searched. The GATT module uses the Characteristic's range.
- maxCharacteristicCount – **[in]** Maximum number of characteristics to be filled.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_DiscoverCharacteristicOfServiceByUuid(*deviceId_t* deviceId, *bleUuidType_t* uuidType, const *bleUuid_t* *pUuid, const *gattService_t* *pService, *gattCharacteristic_t* *aOutCharacteristics, uint8_t maxCharacteristicCount, uint8_t *pOutDiscoveredCount)

Initializes the Characteristic Discovery procedure for a given Service, with a given UUID.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- uuidType – **[in]** Characteristic UUID type.
- pUuid – **[in]** Characteristic UUID.
- pService – **[in]** The service within which characteristics should be searched.
- aOutCharacteristics – **[out]** The allocated array of Characteristics to be filled.
- maxCharacteristicCount – **[in]** Maximum number of characteristics to be filled.
- pOutDiscoveredCount – **[out]** The actual number of characteristics discovered.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_DiscoverAllCharacteristicDescriptors(*deviceId_t* deviceId, *gattCharacteristic_t* *pIoCharacteristic, uint16_t endingHandle, uint8_t maxDescriptorCount)

Initializes the Characteristic Descriptor Discovery procedure for a given Characteristic.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback. The endingHandle parameter should be known by the application if Characteristic Discovery was performed, i.e., if the next Characteristic declaration handle is known, then subtract 1 to obtain the endingHandle for the current Characteristic. If the last handle of the Characteristic is still unknown, set the endingHandle parameter to 0xFFFF.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- pIoCharacteristic – **[inout]** The characteristic within which descriptors should be searched. The GATT module uses the Characteristic's handle and fills each descriptor's handle and UUID.
- endingHandle – **[in]** The last handle of the Characteristic.
- maxDescriptorCount – **[in]** Maximum number of descriptors to be filled.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_ReadCharacteristicValue(*deviceId_t* deviceId, *gattCharacteristic_t* *pIoCharacteristic, uint16_t maxReadBytes)

Initializes the Characteristic Read procedure for a given Characteristic.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- pIoCharacteristic – **[inout]** The characteristic whose value must be read. The GATT module uses the value handle and fills the value and length.
- maxReadBytes – **[in]** Maximum number of bytes to be read.

Return values

- gBleSuccess_c –

- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_ReadUsingCharacteristicUuid(*deviceId_t* deviceId, *bleUuidType_t* uuidType, const *bleUuid_t* *pUuid, const *gattHandleRange_t* *pHandleRange, uint8_t *aOutBuffer, uint16_t maxReadBytes, uint16_t *pOutActualReadBytes)

Initializes the Characteristic Read By UUID procedure.

Remark

This procedure returns the Characteristics found within the specified range with the specified UUID. aOutBuffer will contain the Handle-Value pair length (1 byte), then Handle-Value pairs for all Characteristic Values found with the specified UUID.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- uuidType – **[in]** Characteristic UUID type.
- pUuid – **[in]** Characteristic UUID.
- pHandleRange – **[in]** Handle range for the search or NULL. If this is NULL, the search range is 0x0001-0xffff.
- aOutBuffer – **[out]** The allocated buffer to read into.
- maxReadBytes – **[in]** Maximum number of bytes to be read.
- pOutActualReadBytes – **[out]** The actual number of bytes read.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_ReadMultipleCharacteristicValues(*deviceId_t* deviceId, uint8_t cNumCharacteristics, *gattCharacteristic_t* *aIoCharacteristics)

Initializes the Characteristic Read Multiple procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- aIoCharacteristics – **[inout]** Array of the characteristics whose values are to be read. The GATT module uses each Characteristic's value handle and maxValueLength fills each value and length.
- cNumCharacteristics – **[in]** Number of characteristics in the array.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_WriteCharacteristicValue(*deviceId_t* deviceId, const *gattCharacteristic_t* *pCharacteristic, uint16_t valueLength, const uint8_t *aValue, bool_t withoutResponse, bool_t signedWrite, bool_t doReliableLongCharWrites, const uint8_t *aCsrk)

Initializes the Characteristic Write procedure for a given Characteristic.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- pCharacteristic – **[in]** The characteristic whose value must be written. The GATT module uses the value handle.
- valueLength – **[in]** Number of bytes to be written.
- aValue – **[in]** Array of bytes to be written.
- withoutResponse – **[in]** Indicates if a Write Command is used.
- signedWrite – **[in]** Indicates if a Signed Write is performed.
- doReliableLongCharWrites – **[in]** Indicates Reliable Long Writes.
- aCsrk – **[in]** The CSRK (gcCsrkSize_d bytes) if signedWrite is TRUE, ignored otherwise.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleOverflow_c – TX queue for device is full.

- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_ReadCharacteristicDescriptor(*deviceId_t* deviceId, *gattAttribute_t* *pIoDescriptor, uint16_t maxReadBytes)

Initializes the Characteristic Descriptor Read procedure for a given Characteristic Descriptor.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- pIoDescriptor – **[inout]** The characteristic descriptor whose value must be read. The GATT module uses the attribute's handle and fills the attribute's value and length.
- maxReadBytes – **[in]** Maximum number of bytes to be read.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_WriteCharacteristicDescriptor(*deviceId_t* deviceId, const *gattAttribute_t* *pDescriptor, uint16_t valueLength, const uint8_t *aValue)

Initializes the Characteristic Descriptor Write procedure for a given Characteristic Descriptor.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- pDescriptor – **[in]** The characteristic descriptor whose value must be written. The GATT module uses the attribute's handle.
- valueLength – **[in]** Number of bytes to be written.
- aValue – **[in]** Array of bytes to be written.

Return values

- gBleSuccess_c –

- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_ReadMultipleVariableCharacteristicValues(*deviceId_t* deviceId, uint8_t cNumCharacteristics, *gattCharacteristic_t* *pIoCharacteristics)

Initializes the Read Multiple Variable Length Characteristic Values procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- cNumCharacteristics – **[in]** Number of characteristics in the array.
- pIoCharacteristics – **[in]** Pointer to the array of the characteristics whose values are to be read.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_RegisterEnhancedProcedureCallback(*gattClientEnhancedProcedureCallback_t* callback)

Installs the application callback for the GATT Client module Procedures on Enhanced ATT bearers.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_RegisterEnhancedNotificationCallback(*gattClientEnhancedNotificationCallback_t* callback)

Installs the application callback for Server Notifications.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_RegisterEnhancedIndicationCallback(*gattClientEnhancedIndicationCallback_t* callback)

Installs the application callback for Server Indications.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_RegisterEnhancedMultipleValueNotificationCallback(*gattClientEnhancedMultipleValueNotific* callback)

Installs the application callback for Server Multiple Value Notification.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedDiscoverAllPrimaryServices(*deviceId_t* deviceId, *bearerId_t* bearerId, *gattService_t* *aOutPrimaryServices, uint8_t maxServiceCount, uint8_t *pOutDiscoveredCount)

Initializes the Primary Service Discovery procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- aOutPrimaryServices – **[out]** Statically allocated array of gattService_t. The GATT module fills each Service's handle range and UUID.
- maxServiceCount – **[in]** Maximum number of services to be filled.
- pOutDiscoveredCount – **[out]** The actual number of services discovered.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedDiscoverPrimaryServicesByUuid(*deviceId_t* deviceId, *bearerId_t* bearerId, *bleUuidType_t* uuidType, const *bleUuid_t* *pUuid, *gattService_t* *aOutPrimaryServices, uint8_t maxServiceCount, uint8_t *pOutDiscoveredCount)

Initializes the Primary Service Discovery By UUID procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- uuidType – **[in]** Service UUID type.
- pUuid – **[in]** Service UUID.

- aOutPrimaryServices – **[out]** Statically allocated array of gattService_t. The GATT module fills each Service's handle range.
- maxServiceCount – **[in]** Maximum number of services to be filled.
- pOutDiscoveredCount – **[out]** The actual number of services discovered.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedFindIncludedServices(*deviceId_t* deviceId, *bearerId_t* bearerId, *gattService_t* *pIoService, uint8_t maxServiceCount)

Initializes the Find Included Services procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- pIoService – **[inout]** The service within which inclusions should be searched. The GATT module uses the Service's handle range and fills the included Services' handle ranges, UUID types and the UUIDs if they are 16-bit UUIDs.
- maxServiceCount – **[in]** Maximum number of included services to be filled.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedDiscoverAllCharacteristicsOfService(*deviceId_t* deviceId, *bearerId_t* bearerId, *gattService_t* *pIoService, uint8_t maxCharacteristicCount)

Initializes the Characteristic Discovery procedure for a given Service.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- pIoService – **[inout]** The service within which characteristics should be searched. The GATT module uses the Characteristic's range.
- maxCharacteristicCount – **[in]** Maximum number of characteristics to be filled.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedDiscoverCharacteristicOfServiceByUuid(*deviceId_t* deviceId, *bearerId_t* bearerId, *bleUuidType_t* uuidType, const *bleUuid_t* *pUuid, const *gattService_t* *pService, *gattCharacteristic_t* *aOutCharacteristics, uint8_t maxCharacteristicCount, uint8_t *pOutDiscoveredCount)

Initializes the Characteristic Discovery procedure for a given Service, with a given UUID.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- uuidType – **[in]** Characteristic UUID type.
- pUuid – **[in]** Characteristic UUID.
- pService – **[in]** The service within which characteristics should be searched.
- aOutCharacteristics – **[out]** The allocated array of Characteristics to be filled.
- maxCharacteristicCount – **[in]** Maximum number of characteristics to be filled.

- pOutDiscoveredCount – **[out]** The actual number of characteristics discovered.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedDiscoverAllCharacteristicDescriptors(*deviceId_t* deviceId, *bearerId_t* bearerId, *gattCharacteristic_t* *pIoCharacteristic, uint16_t endingHandle, uint8_t maxDescriptorCount)

Initializes the Characteristic Descriptor Discovery procedure for a given Characteristic.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback. The endingHandle parameter should be known by the application if Characteristic Discovery was performed, i.e., if the next Characteristic declaration handle is known, then subtract 1 to obtain the endingHandle for the current Characteristic. If the last handle of the Characteristic is still unknown, set the endingHandle parameter to 0xFFFF.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- pIoCharacteristic – **[inout]** The characteristic within which descriptors should be searched. The GATT module uses the Characteristic's handle and fills each descriptor's handle and UUID.
- endingHandle – **[in]** The last handle of the Characteristic.
- maxDescriptorCount – **[in]** Maximum number of descriptors to be filled.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedReadCharacteristicValue(*deviceId_t* deviceId, *bearerId_t* bearerId, *gattCharacteristic_t* *pIoCharacteristic, uint16_t maxReadBytes)

Initializes the Characteristic Read procedure for a given Characteristic.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- pIoCharacteristic – **[inout]** The characteristic whose value must be read. The GATT module uses the value handle and fills the value and length.
- maxReadBytes – **[in]** Maximum number of bytes to be read.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedReadUsingCharacteristicUuid(*deviceId_t* deviceId, *bearerId_t* bearerId, *bleUuidType_t* uuidType, const *bleUuid_t* *pUuid, const *gattHandleRange_t* *pHandleRange, uint8_t *aOutBuffer, uint16_t maxReadBytes, uint16_t *pOutActualReadBytes)

Initializes the Characteristic Read By UUID procedure.

Remark

This procedure returns the Characteristics found within the specified range with the specified UUID. aOutBuffer will contain the Handle-Value pair length (1 byte), then Handle-Value pairs for all Characteristic Values found with the specified UUID.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- uuidType – **[in]** Characteristic UUID type.
- pUuid – **[in]** Characteristic UUID.
- pHandleRange – **[in]** Handle range for the search or NULL. If this is NULL, the search range is 0x0001-0xffff.

- aOutBuffer – **[out]** The allocated buffer to read into.
- maxReadBytes – **[in]** Maximum number of bytes to be read.
- pOutActualReadBytes – **[out]** The actual number of bytes read.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedReadMultipleCharacteristicValues(*deviceId_t* deviceId, *bearerId_t* bearerId, uint8_t cNumCharacteristics, *gattCharacteristic_t* *aIoCharacteristics)

Initializes the Characteristic Read Multiple procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- aIoCharacteristics – **[inout]** Array of the characteristics whose values are to be read. The GATT module uses each Characteristic's value handle and maxValueLength fills each value and length.
- cNumCharacteristics – **[in]** Number of characteristics in the array.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedWriteCharacteristicValue(*deviceId_t* deviceId, *bearerId_t* bearerId, const *gattCharacteristic_t* *pCharacteristic, uint16_t valueLength, const uint8_t *aValue, bool_t withoutResponse, bool_t doReliableLongCharWrites, const uint8_t *aCsrk)

Initializes the Characteristic Write procedure for a given Characteristic.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- pCharacteristic – **[in]** The characteristic whose value must be written. The GATT module uses the value handle.
- valueLength – **[in]** Number of bytes to be written.
- aValue – **[in]** Array of bytes to be written.
- withoutResponse – **[in]** Indicates if a Write Command is used.
- signedWrite – **[in]** Indicates if a Signed Write is performed.
- doReliableLongCharWrites – **[in]** Indicates Reliable Long Writes.
- aCsrk – **[in]** The CSRK (gcCsrkSize_d bytes) if signedWrite is TRUE, ignored otherwise.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOverflow_c – TX queue for device is full.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedReadCharacteristicDescriptor(*deviceId_t* deviceId, *bearerId_t* bearerId, *gattAttribute_t* *pIoDescriptor, uint16_t maxReadBytes)

Initializes the Characteristic Descriptor Read procedure for a given Characteristic Descriptor.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- pIoDescriptor – **[inout]** The characteristic descriptor whose value must be read. The GATT module uses the attribute's handle and fills the attribute's value and length.
- maxReadBytes – **[in]** Maximum number of bytes to be read.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedWriteCharacteristicDescriptor(*deviceId_t* deviceId, *bearerId_t* bearerId, const *gattAttribute_t* *pDescriptor, uint16_t valueLength, const uint8_t *aValue)

Initializes the Characteristic Descriptor Write procedure for a given Characteristic Descriptor.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- pDescriptor – **[in]** The characteristic descriptor whose value must be written. The GATT module uses the attribute's handle.
- valueLength – **[in]** Number of bytes to be written.
- aValue – **[in]** Array of bytes to be written.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedReadMultipleVariableCharacteristicValues(*deviceId_t* deviceId, *bearerId_t* bearerId, uint8_t cNumCharacteristics, *gattCharacteristic_t* *pIoCharacteristics)

Initializes the Read Multiple Variable Length Characteristic Values procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- cNumCharacteristics – **[in]** Number of characteristics in the array.
- pIoCharacteristics – **[in]** Pointer to the array of the characteristics whose values are to be read.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

GattClient_SimpleCharacteristicWrite(deviceId, pChar, valueLength, aValue)

Executes the basic Characteristic Write operation (with server confirmation).

Parameters

- deviceId – **[in]** Device ID of the connected GATT Server.
- pChar – **[in]** Pointer to the Characteristic being written.
- valueLength – **[in]** Size in bytes of the value to be written.
- aValue – **[in]** Array of bytes to be written.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOverflow_c – TX queue for device is full.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

GattClient_CharacteristicWriteWithoutResponse(deviceId, pChar, valueLength, aValue)

Executes the Characteristic Write Without Response operation.

Parameters

- deviceId – **[in]** Device ID of the connected GATT Server.
- pChar – **[in]** Pointer to the Characteristic being written.
- valueLength – **[in]** Size in bytes of the value to be written.
- aValue – **[in]** Array of bytes to be written.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOverflow_c – TX queue for device is full.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

GattClient_CharacteristicSignedWrite(deviceId, pChar, valueLength, aValue, aCsrk)

Executes the Characteristic Signed Write Without Response operation.

Parameters

- deviceId – **[in]** Device ID of the connected GATT Server.
- pChar – **[in]** Pointer to the Characteristic being written.
- valueLength – **[in]** Size in bytes of the value to be written.
- aValue – **[in]** Array of bytes to be written.
- aCsrk – **[in]** CSRK to be used for data signing.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOverflow_c – TX queue for device is full.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

GATT Server

enum gattServerEventType_t

GATT Server Event type enumeration

Values:

enumerator gEvtMtuChanged_c

ATT_MTU was changed after the MTU exchange.

enumerator gEvtHandleValueConfirmation_c

Received a Handle Value Confirmation from the Client.

enumerator gEvtAttributeWritten_c

An attribute registered with GattServer_RegisterHandlesForWriteNotifications was written. After receiving this event, application must call GattServer_SendAttributeWrittenStatus. Application must write the Attribute in the Database if it considers necessary.

enumerator gEvtCharacteristicCccdWritten_c

A CCCD was written. Application should save the CCCD value with Gap_SaveCccd.

enumerator gEvtAttributeWrittenWithoutResponse_c

An attribute registered with GattServer_RegisterHandlesForWriteNotifications was written without response (with ATT Write Command). Application must write the Attribute Value in the Database if it considers necessary.

enumerator gEvtError_c

An error appeared during a Server-initiated procedure.

enumerator gEvtLongCharacteristicWritten_c

A long characteristic was written.

enumerator gEvtAttributeRead_c

An attribute registered with GattServer_RegisterHandlesForReadNotifications is being read. After receiving this event, application must call GattServer_SendAttributeReadStatus.

enumerator gEvtInvalidPduReceived_c

An invalid PDU was received from Client. Application decides if disconnection is required

enum gattServerProcedureType_t

Server-initiated procedure type enumeration

Values:

enumerator gSendAttributeWrittenStatus_c

Procedure initiated by GattServer_SendAttributeWrittenStatus.

enumerator gSendAttributeReadStatus_c

Procedure initiated by GattServer_SendAttributeReadStatus.

enumerator gSendNotification_c

Procedure initiated by GattServer_SendNotification.

enumerator gSendIndication_c

Procedure initiated by GattServer_SendIndication.

enumerator gSendMultipleValNotification_c

Procedure initiated by GattServer_SendMultipleHandleValueNotification.

typedef void (*gattServerCallback_t)(*deviceId_t* deviceId, *gattServerEvent_t* *pServerEvent)

GATT Server Callback prototype

typedef void (*gattServerEnhancedCallback_t)(*deviceId_t* deviceId, *bearerId_t* bearerId, *gattServerEvent_t* *pServerEvent)

GATT Server Enhanced Callback prototype

bleResult_t GattServer_Init(void)

Initializes the GATT Server module.

Remark

Application does not need to call this function if *Gatt_Init()* is called.

Remark

This function executes synchronously.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_CheckServerSupportedFeaturesCharacteristicValue(void)

If the GAP module is present, this function is called internally by *Ble_HostInitialize()*. Signals support for EATT and Robust Caching, when appropriate, by setting the corresponding BIT for each feature in the value of the Server Supported Features characteristic of the database.

Remark

This function executes synchronously.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_RegisterCallback(*gattServerCallback_t* callback)

Installs an application callback for the GATT Server module.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application-defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_RegisterHandlesForWriteNotifications(uint8_t handleCount, const uint16_t *aAttributeHandles)

Registers the attribute handles that will be notified through the GATT Server callback when a GATT Client attempts to modify the attributes' values.

Remark

The application is responsible for actually writing the new requested values in the GATT database. Service and profile-specific control-point characteristics should have their value handles in this list so that the application may get notified when a GATT Client writes it.

Remark

This function executes synchronously.

Parameters

- handleCount – **[in]** Number of handles in array.
- aAttributeHandles – **[in]** Array of handles.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOverflow_c – The maximum number of supported handles for write notifications has been reached.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_UnregisterHandlesForWriteNotifications(uint8_t handleCount, const uint16_t *aAttributeHandles)

Unregisters the attribute handles that will be notified through the GATT Server callback when a GATT Client attempts to modify the attributes' values.

Remark

To unregister all the list, pass 0 count and NULL.

Remark

This function executes synchronously.

Parameters

- handleCount – **[in]** Number of handles in array.
- aAttributeHandles – **[in]** Array of handles.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_SendAttributeWrittenStatus(*deviceId_t* deviceId, uint16_t attributeHandle, uint8_t status)

Responds to an intercepted attribute write operation.

Remark

This function must be called by the application when receiving the gEvtAttributeWritten_c Server event. The status value may contain application- or profile-defined error codes.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- attributeHandle – **[in]** The attribute handle that was written.
- status – **[in]** The status of the write operation. If this parameter is equal to gAttErrCodeNoError_c then an ATT Write Response will be sent to the peer. Otherwise, an ATT Error Response with the provided status will be sent to the peer.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_RegisterHandlesForReadNotifications(uint8_t handleCount, const uint16_t *aAttributeHandles)

Registers the attribute handles that will be notified through the GATT Server callback when a GATT Client attempts to read the attributes' values.

Remark

The application may modify the attribute's value in the GATT Database before sending the response with GattServer_SendAttributeReadStatus.

Remark

This function executes synchronously.

Parameters

- handleCount – **[in]** Number of handles in array.
- aAttributeHandles – **[in]** Array of handles.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleOverflow_c – The maximum number of supported handles for read notifications has been reached.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_UnregisterHandlesForReadNotifications(uint8_t handleCount, const uint16_t *aAttributeHandles)

Unregisters the attribute handles that will be notified through the GATT Server callback when a GATT Client attempts to read the attributes' values.

Remark

To unregister all the list, pass 0 count and NULL.

Remark

This function executes synchronously.

Parameters

- handleCount – **[in]** Number of handles in array.
- aAttributeHandles – **[in]** Array of handles.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_SendAttributeReadStatus(*deviceId_t* deviceId, uint16_t attributeHandle, uint8_t status)

Responds to an intercepted attribute read operation.

Remark

This function must be called by the application when receiving the gEvtAttributeRead_c Server event. The status value may contain application- or profile-defined error codes.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- attributeHandle – **[in]** The attribute handle that was being read.
- status – **[in]** The status of the read operation. If this parameter is equal to gAttErrCodeNoError_c then an ATT Read Response will be sent to the peer containing the attribute value from the GATT Database. Otherwise, an ATT Error Response with the provided status will be sent to the peer.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_SendNotification(*deviceId_t* deviceId, uint16_t handle)

Sends a notification to a peer GATT Client using the Characteristic Value from the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.

- handle – **[in]** Handle of the Value of the Characteristic to be notified.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_SendIndication(*deviceId_t* deviceId, uint16_t handle)

Sends an indication to a peer GATT Client using the Characteristic Value from the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- handle – **[in]** Handle of the Value of the Characteristic to be indicated.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_SendInstantValueNotification(*deviceId_t* deviceId, uint16_t handle, uint16_t valueLength, const uint8_t *aValue)

Sends a notification to a peer GATT Client with data given as parameter, ignoring the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- handle – **[in]** Handle of the Value of the Characteristic to be notified.
- valueLength – **[in]** Length of data to be notified.
- aValue – **[in]** Data to be notified.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOverflow_c – TX queue for device is full.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_SendMultipleHandleValueNotification(*deviceId_t* deviceId, uint32_t totalLength, const uint8_t *pHandleLengthValueList)

Sends a notification to a peer GATT Client with data given as parameter, ignoring the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.

- totalLength – **[in]** Length of the handle, value, value length tuples.
- pHandleLengthValueList – **[in]** Pointer to data to be notified.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_SendInstantValueIndication(*deviceId_t* deviceId, uint16_t handle, uint16_t valueLength, const uint8_t *aValue)

Sends an indication to a peer GATT Client with data given as parameter, ignoring the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- handle – **[in]** Handle of the Value of the Characteristic to be indicated.
- valueLength – **[in]** Length of data to be indicated.
- aValue – **[in]** Data to be indicated.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleOverflow_c – TX queue for device is full.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_RegisterUniqueHandlesForNotifications(bool_t bWrite, bool_t bRead)

Registers all GATT DB dynamic attribute handles with unique value buffers to be notified through the GATT Server callback when a GATT Client attempts to read/write the attributes' values.

Remark

This function executes synchronously.

Remark

This function should be called when adding GATT DB unique value buffer characteristics or descriptors.

Parameters

- bWrite – **[in]** Enables/Disables write notifications.
- bRead – **[in]** Enables/Disables read notifications.

Return values

- gBleSuccess_c –

- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_RegisterEnhancedCallback(*gattServerEnhancedCallback_t* callback)

Installs an application callback for the Enhanced ATT GATT Server module.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application-defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_EnhancedSendAttributeWrittenStatus(*deviceId_t* deviceId, *bearerId_t* bearerId, uint16_t attributeHandle, uint8_t status)

Responds to an intercepted attribute write operation.

Remark

This function must be called by the application when receiving the gEvtAttributeWritten_c Server event. The status value may contain application- or profile-defined error codes.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- bearerId – **[in]** The Enhanced ATT bearer ID of the connected peer.
- attributeHandle – **[in]** The attribute handle that was written.
- status – **[in]** The status of the write operation. If this parameter is equal to gAttErrCodeNoError_c then an ATT Write Response will be sent to the peer. Else an ATT Error Response with the provided status will be sent to the peer.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_EnhancedSendAttributeReadStatus(*deviceId_t* deviceId, *bearerId_t* bearerId, uint16_t attributeHandle, uint8_t status)

Responds to an intercepted attribute read operation.

Remark

This function must be called by the application when receiving the gEvtAttributeRead_c Server event. The status value may contain application- or profile-defined error codes.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- bearerId – **[in]** The Enhanced ATT bearer ID of the connected peer.
- attributeHandle – **[in]** The attribute handle that was being read.
- status – **[in]** The status of the read operation. If this parameter is equal to gAttErrCodeNoError_c then an ATT Read Response will be sent to the peer containing the attribute value from the GATT Database. Else an ATT Error Response with the provided status will be sent to the peer.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_EnhancedSendNotification(*deviceId_t* deviceId, *bearerId_t* bearerId, uint16_t handle)

Sends a notification to a peer GATT Client using the Characteristic Value from the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- bearerId – **[in]** The Enhanced ATT bearer ID of the connected peer.
- handle – **[in]** Handle of the Value of the Characteristic to be notified.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_EnhancedSendIndication(*deviceId_t* deviceId, *bearerId_t* bearerId, uint16_t handle)

Sends an indication to a peer GATT Client using the Characteristic Value from the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- bearerId – **[in]** The Enhanced ATT bearer ID of the connected peer.

- handle – **[in]** Handle of the Value of the Characteristic to be indicated.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_EnhancedSendInstantValueNotification(*deviceId_t* deviceId, *bearerId_t* bearerId, uint16_t handle, uint16_t valueLength, const uint8_t *aValue)

Sends a notification to a peer GATT Client with data given as parameter, ignoring the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- bearerId – **[in]** The Enhanced ATT bearer ID of the connected peer.
- handle – **[in]** Handle of the Value of the Characteristic to be notified.
- valueLength – **[in]** Length of data to be notified.
- aValue – **[in]** Data to be notified.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOverflow_c – TX queue for device is full.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_EnhancedSendMultipleHandleValueNotification(*deviceId_t* deviceId, *bearerId_t* bearerId, uint32_t totalLength, const uint8_t *pHandleLengthValueList)

Sends a notification to a peer GATT Client with data given as parameter, ignoring the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- bearerId – **[in]** The Enhanced ATT bearer ID of the connected peer.
- totalLength – **[in]** Length of the handle, value, value length tuples.
- pHandleLengthValueList – **[in]** Pointer to data to be notified.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_EnhancedSendInstantValueIndication(*deviceId_t* deviceId, *bearerId_t* bearerId, uint16_t handle, uint16_t valueLength, const uint8_t *aValue)

Sends an indication to a peer GATT Client with data given as parameter, ignoring the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- bearerId – **[in]** The Enhanced ATT bearer ID of the connected peer.
- handle – **[in]** Handle of the Value of the Characteristic to be indicated.
- valueLength – **[in]** Length of data to be indicated.
- aValue – **[in]** Data to be indicated.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOverflow_c – TX queue for device is full.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

struct gattServerMtuChangedEvent_t

#include <gatt_server_interface.h> GATT Server MTU Changed Event structure

Public Members

uint16_t newMtu

Value of the agreed ATT_MTU for this connection.

struct gattServerAttributeWrittenEvent_t

#include <gatt_server_interface.h> GATT Server Attribute Written Event structure

Public Members

uint16_t handle

Handle of the attribute.

uint16_t cValueLength

Length of the attribute value array.

uint8_t *aValue

Attribute value array attempted to be written.

bearerId_t bearerId

Used by EATT. Send response on the same bearer. For ATT value is 0.

struct gattServerLongCharacteristicWrittenEvent_t

#include <gatt_server_interface.h> GATT Server Long Characteristic Written Event structure

Public Members

uint16_t handle

Handle of the Characteristic Value.

uint16_t cValueLength

Length of the value written.

uint8_t *aValue

Pointer to the attribute value in the database.

struct gattServerCccdWrittenEvent_t

#include <gatt_server_interface.h> GATT Server CCCD Written Event structure

Public Members

uint16_t handle

Handle of the CCCD attribute.

gattCccdFlags_t newCccd

New value of the CCCD.

struct gattServerAttributeReadEvent_t

#include <gatt_server_interface.h> GATT Server Attribute Read Event structure

Public Members

uint16_t handle

Handle of the attribute.

struct gattServerProcedureError_t

#include <gatt_server_interface.h> Server-initiated procedure error structure

Public Members

gattServerProcedureType_t procedureType

Procedure that generated error.

bleResult_t error

Error generated.

struct gattServerInvalidPdu_t

#include <gatt_server_interface.h> ATT PDU that generated the error

Public Members

attOpcode_t attOpCode
The invalid ATT op code that generated the error

struct gattServerEvent_t
#include <gatt_server_interface.h> GATT Server Event structure: type + data.

Public Members

gattServerEventType_t eventType
Event type.

union *gattServerEvent_t* eventData
Event data : selected according to event type.

union eventData

Public Members

gattServerMtuChangedEvent_t mtuChangedEvent
For event type gEvtMtuChanged_c: the new value of the ATT_MTU.

gattServerAttributeWrittenEvent_t attributeWrittenEvent
For event types gEvtAttributeWritten_c, gEvtAttributeWrittenWithoutResponse_c: handle and value of the attempted write.

gattServerCccdWrittenEvent_t charCccdWrittenEvent
For event type gEvtCharacteristicCccdWritten_c: handle and value of the CCCD.

gattServerProcedureError_t procedureError
For event type gEvtError_c: error that terminated a Server-initiated procedure.

gattServerLongCharacteristicWrittenEvent_t longCharWrittenEvent
For event type gEvtLongCharacteristicWritten_c: handle and value.

gattServerAttributeReadEvent_t attributeReadEvent
For event types gEvtAttributeRead_c: handle of the attempted read.

gattServerInvalidPdu_t attributeOpCode
For event type gEvtInvalidPduReceived_c: the ATT PDU that generated the error

GATT Database

enum gattCharacteristicPropertiesBitFields_tag
Values:

enumerator gGattCharPropNone_c
No Properties selected.

enumerator gGattCharPropBroadcast_c
Characteristic can be broadcast.

enumerator gGattCharPropRead_c
Characteristic can be read.

enumerator gGattCharPropWriteWithoutRsp_c
Characteristic can be written without response.

enumerator gGattCharPropWrite_c
Characteristic can be written with response.

enumerator gGattCharPropNotify_c
Characteristic can be notified.

enumerator gGattCharPropIndicate_c
Characteristic can be indicated.

enumerator gGattCharPropAuthSignedWrites_c
Characteristic can be written with signed data.

enumerator gGattCharPropExtendedProperties_c
Extended Characteristic properties.

enum gattDbAccessType_t
Attribute access type
Values:

enumerator gAccessRead_c

enumerator gAccessWrite_c

enumerator gAccessNotify_c

typedef uint8_t gattCharacteristicPropertiesBitFields_t
Bit fields for Characteristic properties

typedef uint8_t gattAttributePermissionsBitFields_t
Bit fields for attribute permissions

uint16_t gGattDbAttributeCount_c
The number of attributes in the GATT Database.

gattDbAttribute_t *gattDatabase
Reference to the GATT database

uint16_t mServerServiceChangedCharHandle

uint16_t mServerServiceChangedCCCDHandle

uint32_t gGattDynamicAttrSize

uint8_t gaGattDynamicAttrBlob[]

uint32_t gGattDynamicValSize

uint8_t gaGattDynamicValBlob[]

uint16_t GattDb_GetIndexOfHandle(uint16_t handle)

Returns the database index for a given attribute handle.

Parameters

- handle – **[in]** The attribute handle.

Returns

The index of the given attribute in the database or gGattDbInvalidHandleIndex_d.

uint16_t GattDb_ServiceStartHandle(uint16_t handle)

Returns the handle of the service to which the given attribute belongs.

Parameters

- handle – **[in]** The attribute handle.

Returns

The handle of the service or gGattDbInvalidHandleIndex_d.

bleResult_t GattDb_FindServiceRange(uint16_t serviceHandle, uint16_t *pOutStartIndex, uint16_t *pOutAttributeCount)

Finds the start index and attribute count for a given service.

Parameters

- serviceHandle – **[in]** The service handle.
- pOutStartIndex – **[in]** The index in the database where the service declaration begins.
- pOutAttributeCount – **[in]** The number of attributes contained by the service.

Return values

- gBleSuccess_c –
- gGattDbInvalidHandleIndex_d – Service does not exist in gatt database.

uint16_t GattDb_GetAttributeValueSize(uint16_t handle)

Returns the value length for a given attribute handle.

Parameters

- handle – **[in]** The attribute handle.

Returns

The length of the value of the attribute at the given handle or maxVariableValueLength in case of variable length attributes.

bleResult_t GattDb_ComputeDatabaseHash(void)

Computes the database hash for a static or a dynamic database.

Parameters

- void. –

Return values

- gBleSuccess_c –
- gBleInvalidState_c – Database not initialized or empty.
- gBleOutOfMemory_c – Could not allocate memory for the database content used to compute the database hash.
- gGattDbInvalidHandleIndex_d – Service does not exist in gatt database.

bleResult_t GattDb_Init(void)

Initializes the GATT database at runtime.

Remark

This function should be called only once at device start-up. In the current stack implementation, it is called internally by Ble_HostInitialize.

Remark

This function executes synchronously.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Could not allocate memory for the GATT dynamic database.
- gBleAlreadyInitialized_c – GATT database already initialized.

bleResult_t GattDb_Deinit(void)

Function performing runtime deinitialization of the GATT database.

Remark

This function has effect for dynamic data base only .

Parameters

- none. –

Return values

- gBleSuccess_c –
- gBleInvalidState_c – GATT dynamic database not initialized.

bleResult_t GattDb_WriteAttribute(uint16_t handle, uint16_t valueLength, const uint8_t *aValue)

Writes an attribute from the application level.

This function can be called by the application code to modify an attribute in the database. It should only be used by the application to modify a Characteristic's value based on the application logic (e.g., external sensor readings).

Remark

This function executes synchronously.

Parameters

- handle – **[in]** The handle of the attribute to be written.
- valueLength – **[in]** The number of bytes to be written.
- aValue – **[in]** The source buffer containing the value to be written.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – aValue NULL and length higher than 0.
- gAttStatusBase_c – + gAttErrCodeInvalidHandle_c handle not found in GATT database.
- gGattInvalidValueLength_c – valueLength not equal to attribute value length, or higher than the maximum length for variable size attributes.
- gBleFeatureNotSupported_c – GATT Server not enabled.

bleResult_t GattDb_ReadAttribute(uint16_t handle, uint16_t maxBytes, uint8_t *aOutValue, uint16_t *pOutValueLength)

Reads an attribute from the application level.

This function can be called by the application code to read an attribute in the database.

Remark

This function executes synchronously.

Parameters

- handle – **[in]** The handle of the attribute to be read.
- maxBytes – **[in]** The maximum number of bytes to be received.
- aOutValue – **[out]** The pre-allocated buffer ready to receive the bytes.
- pOutValueLength – **[out]** The actual number of bytes received.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – aOutValue NULL, pOutValueLength NULL or maxBytes 0.
- gAttStatusBase_c – + gAttErrCodeInvalidHandle_c handle not found in GATT database.

- gBleFeatureNotSupported_c – GATT Server not enabled.

bleResult_t GattDb_FindServiceHandle(uint16_t startHandle, *bleUuidType_t* serviceUuidType, const *bleUuid_t* *pServiceUuid, uint16_t *pOutServiceHandle)

Finds the handle of a Service Declaration with a given UUID inside the database.

Remark

This function executes synchronously.

Remark

The startHandle should be set to 0x0001 when this function is called for the first time. If multiple Services with the same UUID are expected, then after the first successful call the function may be called again with the startHandle equal to the found service handle plus one.

Parameters

- startHandle – **[in]** The handle to start the search. Should be 0x0001 on the first call.
- serviceUuidType – **[in]** Service UUID type.
- pServiceUuid – **[in]** Service UUID.
- pOutServiceHandle – **[out]** Pointer to the service declaration handle to be written.

Return values

- gBleSuccess_c – Service Declaration found, handle written in pOutCharValueHandle.
- gGattDbInvalidHandle_c – Invalid Start Handle.
- gBleInvalidParameter_c – pServiceUuid or pOutServiceHandle NULL.
- gGattDbServiceNotFound_c – Service with given UUID not found.
- gBleFeatureNotSupported_c – GATT Server not enabled.

bleResult_t GattDb_FindCharValueHandleInService(uint16_t serviceHandle, *bleUuidType_t* characteristicUuidType, const *bleUuid_t* *pCharacteristicUuid, uint16_t *pOutCharValueHandle)

Finds the handle of a Characteristic Value with a given UUID inside a Service.

The Service is input by its declaration handle.

Remark

This function executes synchronously.

Parameters

- serviceHandle – **[in]** The handle of the Service declaration.
- characteristicUuidType – **[in]** Characteristic UUID type.
- pCharacteristicUuid – **[in]** Characteristic UUID.
- pOutCharValueHandle – **[out]** Pointer to the characteristic value handle to be written.

Return values

- gBleSuccess_c – Characteristic Value found, handle written in pOutCharValueHandle.
- gGattDbInvalidHandle_c – Handle not found or not a Service declaration.
- gBleInvalidParameter_c – pCharacteristicUuid or pOutCharValueHandle NULL.
- gGattDbCharacteristicNotFound_c – Characteristic Value with given UUID not found.
- gBleFeatureNotSupported_c – GATT Server not enabled.

bleResult_t GattDb_FindCccdHandleForCharValueHandle(uint16_t charValueHandle, uint16_t *pOutCccdHandle)

Finds the handle of a Characteristic's CCCD given the Characteristic's Value handle.

Remark

This function executes synchronously.

Parameters

- charValueHandle – **[in]** The handle of the Service declaration.
- pOutCccdHandle – **[out]** Pointer to the CCCD handle to be written.

Return values

- gBleSuccess_c – CCCD found, handle written in pOutCccdHandle.
- gBleInvalidParameter_c – pOutCccdHandle is NULL.
- gGattDbInvalidHandle_c – Invalid Characteristic Value handle.
- gGattDbCccdNotFound_c – CCCD not found for this Characteristic.
- gBleFeatureNotSupported_c – GATT Server not enabled.

bleResult_t GattDb_FindDescriptorHandleForCharValueHandle(uint16_t charValueHandle, *bleUuidType_t* descriptorUuidType, const *bleUuid_t* *pDescriptorUuid, uint16_t *pOutDescriptorHandle)

Finds the handle of a Characteristic Descriptor given the Characteristic's Value handle and Descriptor's UUID.

Remark

This function executes synchronously.

Parameters

- charValueHandle – **[in]** The handle of the Service declaration.
- descriptorUuidType – **[in]** Descriptor's UUID type.
- pDescriptorUuid – **[in]** Descriptor's UUID.
- pOutDescriptorHandle – **[out]** Pointer to the Descriptor handle to be written.

Return values

- gBleSuccess_c – Descriptor found.
- gBleInvalidParameter_c – pDescriptorUuid or pOutDescriptorHandle are NULL.
- gGattDbInvalidHandle_c – Invalid Characteristic Value handle.
- gGattDbDescriptorNotFound_c – Descriptor not found for this Characteristic.
- gBleFeatureNotSupported_c – GATT Server not enabled.

gGattDbInvalidHandleIndex_d

Special value returned by GattDb_GetIndexOfHandle to signal that an invalid attribute handle was given as parameter.

gGattDbInvalidHandle_d

Special value used to mark an invalid attribute handle. Attribute handles are strictly positive.

gPermissionNone_c

No permissions selected.

gPermissionFlagReadable_c

Attribute can be read.

gPermissionFlagReadWithEncryption_c

Attribute may be read only if link is encrypted.

gPermissionFlagReadWithAuthentication_c

Attribute may be read only by authenticated peers.

gPermissionFlagReadWithAuthorization_c

Attribute may be read only by authorized peers.

gPermissionFlagWritable_c

Attribute can be written.

gPermissionFlagWriteWithEncryption_c

Attribute may be written only if link is encrypted.

gPermissionFlagWriteWithAuthentication_c

Attribute may be written only by authenticated peers.

gPermissionFlagWriteWithAuthorization_c

Attribute may be written only by authorized peers.

gGattDatabaseHashSize_c

struct gattDbAttribute_t

#include <gatt_database.h> Attribute structure

Public Members

uint16_t handle

The attribute handle - cannot be 0x0000. The attribute handles need not be consecutive, but must be strictly increasing.

uint16_t permissions

Attribute permissions as defined by the ATT.

uint32_t uuid

The UUID should be read according to the *gattDbAttribute_t.uuidType* member: for 2-byte and 4-byte UUIDs, this contains the value of the UUID; for 16-byte UUIDs, this is a pointer to the allocated 16-byte array containing the UUID.

uint8_t *pValue

A pointer to allocated value array.

uint16_t valueLength

The size of the value array.

uint16_t uuidType

Identifies the length of the UUID; values interpreted according to the *bleUuidType_t* enumeration.

uint16_t maxVariableValueLength

The maximum length of the attribute value array; if this is set to 0, then the attribute's length is fixed and cannot be changed.

Bluetooth Low Energy

enum bleResult_tag

BLE result type - the return value of BLE API functions

Values:

enumerator gBleStatusBase_c

General status base.

enumerator gBleSuccess_c

Function executed successfully.

enumerator gBleInvalidParameter_c
Parameter has an invalid value or is outside the accepted range.

enumerator gBleOverflow_c
An internal limit is reached.

enumerator gBleUnavailable_c
A requested parameter is not available.

enumerator gBleFeatureNotSupported_c
The requested feature is not supported by this stack version.

enumerator gBleOutOfMemory_c
An internal memory allocation failed.

enumerator gBleAlreadyInitialized_c
Ble_HostInitialize function is incorrectly called a second time.

enumerator gBleOsError_c
An error occurred at the OS level.

enumerator gBleUnexpectedError_c
A “should never get here”-type error occurred.

enumerator gBleInvalidState_c
The requested API cannot be called in the current state.

enumerator gBleTimerError_c
Timer allocation failed.

enumerator gBleReassemblyInProgress_c
HCI Packet reassembly was in progress. The old packet was discarded

enumerator gBleNVMError_c
An error occurred when performing an NVM operation

enumerator gBleRngError_c
error generated by a RNG function call e.g. RNG_GetPseudoRandomNo

enumerator gBleSecLibError_c
error generated by a SecLib function call e.g. SecLib_VerifyBluetoothAh

enumerator gHciStatusBase_c
HCI status base.

enumerator gHciSuccess_c
Alias.

enumerator gHciUnknownHciCommand_c

The HCI Command packet opcode is unknown.

enumerator gHciUnknownConnectionIdentifier_c

The connection does not exist or it is of a wrong type.

enumerator gHciHardwareFailure_c

A failure occurred in the Controller.

enumerator gHciPageTimeout_c

A page timed out based on the Page Timeout parameter.

enumerator gHciAuthenticationFailure_c

Pairing or authentication failed. Possible causes: incorrect PIN or Link Key.

enumerator gHciPinOrKeyMissing_c

Pairing failed because of missing PIN or authentication failed because of missing Key.

enumerator gHciMemoryCapacityExceeded_c

The controller doesn't have enough memory to store new parameters.

enumerator gHciConnectionTimeout_c

The link supervision timeout has expired for a connection or the synchronization timeout has expired for a broadcast.

enumerator gHciConnectionLimitExceeded_c

The maximum number of connections has already been reached.

enumerator gHciSynchronousConnectionLimitToADeviceExceeded_c

The maximum number of synchronous connections has already been reached.

enumerator gHciAclConnectionAlreadyExists_c

A connection to this device already exists.

enumerator gHciCommandDisallowed_c

The controller can't process the command at this time.

enumerator gHciConnectionRejectedDueToLimitedResources_c

The connection was rejected due to limited resources.

enumerator gHciConnectionRejectedDueToSecurityReasons_c

The connection was rejected because the security requirements were not fulfilled.

enumerator gHciConnectionRejectedDueToUnacceptableBdAddr_c

The connection was rejected because the device does not accept the given BD_ADDR. A possible cause is that the device only accepts connections from specific BD_ADDRs.

enumerator gHciConnectionAcceptTimeoutExceeded_c

The connection accept timeout for this connection has been exceeded.

enumerator gHciUnsupportedFeatureOrParameterValue_c

The feature or parameter in the HCI command is not supported.

enumerator gHciInvalidHciCommandParameters_c

At least one of the HCI command parameters is invalid.

enumerator gHciRemoteUserTerminatedConnection_c

The remote device's user terminated the connection or stopped broadcasting.

enumerator gHciRemoteDeviceTerminatedConnectionLowResources_c

The remote device terminated the connection due to low resources.

enumerator gHciRemoteDeviceTerminatedConnectionPowerOff_c

The remote device terminated the connection because it will power off.

enumerator gHciConnectionTerminatedByLocalHost_c

The local device terminated the connection, synchronization with a broadcaster or stopped broadcasting.

enumerator gHciRepeatedAttempts_c

The Controller disallows the authentication or pairing because not enough time has passed since the failed attempt.

enumerator gHciPairingNotAllowed_c

The device does not allow pairing.

enumerator gHciUnknownLpmPdu_c

The Controller has received an unknown LMP code.

enumerator gHciUnsupportedRemoteFeature_c

The remote device doesn't support the feature associated with the issued command, LMP PDU or LL Control PDU.

enumerator gHciScoOffsetRejected_c

The offset requested in the LMP_SCO_LINK_REQ PDU has been rejected.

enumerator gHciScoIntervalRejected_c

The interval requested in the LMP_SCO_LINK_REQ PDU has been rejected.

enumerator gHciScoAirModeRejected_c

The air mode requested in the LMP_SCO_LINK_REQ PDU has been rejected.

enumerator gHciInvalidLpmParameters_c

Some LMP PDU or LL Control PDU parameters were invalid.

enumerator gHciUnspecifiedError_c

No other error code was appropriate.

enumerator gHciUnsupportedLpmParameterValue_c

An LMP PDU or LL Control PDU contains at least one parameter value not supported by the Controller at this time.

enumerator gHciRoleChangeNotAllowed_c

The Controller doesn't allow a role change at this time.

enumerator gHciLLResponseTimeout_c

An LMP transaction failed to respond within the LMP response timeout or an LL transaction failed to respond within the LL response timeout.

enumerator gHciLmpErrorTransactionCollision_c

An LMP transaction or LL procedure has collided with the same transaction or procedure which is already in progress.

enumerator gHciLmpPduNotAllowed_c

A controller sent an LMP PDU with an opcode that isn't allowed.

enumerator gHciEncryptionModeNotAcceptable_c

The requested encryption mode is not allowed at this time.

enumerator gHciLinkKeyCannotBeChanged_c

The link key can't be changed because a fixed unit key is being used.

enumerator gHciRequestedQosNotSupported_c

The requested QoS is not supported.

enumerator gHciInstantPassed_c

An LMP PDU or LL PDU that includes an instant cannot be performed because the instant when this would have occurred has passed.

enumerator gHciPairingWithUnitKeyNotSupported_c

It wasn't possible to pair because a unit key was requested but it is not supported.

enumerator gHciDifferentTransactionCollision_c

An LMP transaction or LL Procedure was started that collides with another one.

enumerator gHciReserved_0x2B_c

enumerator gHciQosNotAcceptableParameter_c

The specified QoS parameters couldn't be accepted at this time.

enumerator gHciQosRejected_c

The specified QoS parameters couldn't be accepted and QoS negotiation should be terminated.

enumerator gHciChannelClassificationNotSupported_c

The Controller can't perform a channel assessment because it isn't supported.

enumerator gHciInsufficientSecurity_c

The HCI command or LMP PDU sent is only possible on an encrypted link.

enumerator gHciParameterOutOfMandatoryRange_c

A parameter value requested is outside the mandatory range of parameters for the given HCI command or LMP PDU. The recipient does not accept that value.

enumerator gHciReserved_0x31_c

enumerator gHciRoleSwitchPending_c

A role switch is pending.

enumerator gHciReserved_0x33_c

enumerator gHciReservedSlotViolation_c

The Synchronous negotiation was terminated with its state set to Reserved Slot Violation.

enumerator gHciRoleSwitchFailed_c

A role switch was attempted but it failed. The original piconet structure is restored.

enumerator gHciExtendedInquiryResponseTooLarge_c

The extended inquiry response, with the requested requirements for FEC, is too large to fit in any of the packet types supported by the Controller.

enumerator gHciSecureSimplePairingNotSupportedByHost_c

The IO capabilities request / response was rejected because the sending Host does not support Secure Simple Pairing even though the receiving Link Manager does.

enumerator gHciHostBusyPairing_c

The Host is busy with another pairing request. Pairing should be retried again later.

enumerator gHciConnectionRejectedDueToNoSuitableChannelFound_c

An appropriate value for the Channel selection operation couldn't be calculated by the Controller.

enumerator gHciControllerBusy_c

The operation was rejected because the Controller was busy.

enumerator gHciUnacceptableConnectionParameters_c

The remote device terminated the connection or rejected a request because of at least one unacceptable connection parameter.

enumerator gHciDirectedAdvertisingTimeout_c

Advertising for a fixed duration completed. For directed advertising, advertising completed without a connection being created.

enumerator gHciConnectionTerminatedDueToMicFailure_c

The connection or the synchronization was terminated because the Message Integrity Check failed.

enumerator gHciConnectionFailedToBeEstablishedOrSyncTimeout_c

The LL initiated a connection / synchronization to periodic advertising but the connection has failed to be established or the LL failed to synchronize with the periodic advertising within 6 periodic advertising events of the first attempt.

enumerator gHciMacConnectionFailed_c

enumerator gHciCoarseClockAdjustmentRejected_c

The Central is unable to make a coarse adjustment to the piconet clock, using the given parameters. It will attempt to move the clock using clock dragging.

enumerator gHciType0SubmapNotDefined_c

The LMP PDU is rejected because the Type 0 submap is not currently defined.

enumerator gHciUnknownAdvertisingIdentifier_c

A command was sent from the Host that should identify an Advertising or Sync handle, but that handle doesn't exist.

enumerator gHciLimitReached_c

The number of operations requested has been reached.

enumerator gHciOperationCancelledByHost_c

A request sent from the Host to the Controller which was still pending has been successfully canceled.

enumerator gHciPacketTooLong_c

An attempt was made to send or receive a packet that exceeds the maximum allowed packet length.

enumerator gHciPacketTooLate_c

Information was provided too late to the Controller.

enumerator gHciPacketTooEarly_c

Information was provided too early to the Controller.

enumerator gHciAlreadyInit_c

HCI has already been initialized.

enumerator gHciInvalidParameter_c

At least one of the HCI command parameters is invalid.

enumerator gHciCallbackNotInstalled_c

Callback was not installed.

enumerator gHciCallbackAlreadyInstalled_c

Callback has already been installed.

enumerator gHciCommandNotSupported_c

The HCI command is not supported.

enumerator gHciEventNotSupported_c

The HCI event is not supported.

enumerator gHciTransportError_c

HCI layer initialization failure. HCI data buffering semaphore allocation error. HCI layer received an unknown packet type. Serial initialization or write failure.

enumerator gCtrlStatusBase_c

Controller status base.

enumerator gCtrlSuccess_c

Alias.

enumerator gL2caStatusBase_c

L2CAP status base.

enumerator gL2caSuccess_c

Alias.

enumerator gL2caAlreadyInit_c

L2CAP has already been initialized.

enumerator gL2caInsufficientResources_c

L2CAP could not allocate resources to perform operations (memory or timers).

enumerator gL2caCallbackNotInstalled_c

Callback was not installed.

enumerator gL2caCallbackAlreadyInstalled_c

Callback has already been installed.

enumerator gL2caLePsmInvalid_c

Invalid LE_PSM value.

enumerator gL2caLePsmAlreadyRegistered_c

LE_PSM has already been registered.

enumerator gL2caLePsmNotRegistered_c

LE_PSM value was not registered.

enumerator gL2caLePsmInsufficientResources_c

No free LE_PSM registration slot was found.

enumerator gL2caChannelInvalid_c

L2CA channel is invalid.

enumerator gL2caChannelClosed_c

L2CA channel is closed.

enumerator gL2caChannelAlreadyConnected_c

L2CA channel is already connected.

enumerator gL2caConnectionParametersRejected_c

Connection parameters were rejected.

enumerator gL2caChannelBusy_c

L2CA channel is busy.

enumerator gL2caInvalidParameter_c

The command contains at least one invalid parameter.

enumerator gL2caInternalError_c

There are connected L2CAP channels for the LE_PSM.

enumerator gSmStatusBase_c

Security Manager status base.

enumerator gSmSuccess_c

Alias.

enumerator gSmNullCBFunction_c

enumerator gSmCommandNotSupported_c

The Security Manager (SM) does not have the required features or version to support this command

enumerator gSmUnexpectedCommand_c

This command is not or cannot be handled in the current context of the SM.

enumerator gSmInvalidCommandCode_c

The provided SM command code is invalid.

enumerator gSmInvalidCommandLength_c

The provided command length is not valid for the SM command code.

enumerator gSmInvalidCommandParameter_c

One of the parameters of the SM command is not valid.

enumerator gSmInvalidDeviceId_c

The provided Device ID is invalid.

enumerator gSmInvalidInternalOperation_c

There is a problem with the internal state of the SM. This should not happen during normal operation. A memory corruption or invalid operation may have occurred.

enumerator gSmInvalidConnectionHandle_c

The target device does not have a valid connection handle. It might be disconnected.

enumerator gSmInproperKeyDistributionField_c

The Responder upper layer has set to “1” one or more flags in the Initiator or Responder Key Distribution Fields from the Pairing Request which were set to “0” by the peer device.

enumerator gSmUnexpectedKeyType_c

The Responder upper layer has set a key type field in the Passkey Request Reply command, which is different than the field negotiated with the peer device.

enumerator gSmUnexpectedPairingTerminationReason_c

The upper layer tried to cancel the pairing procedure with an unexpected pairing failure reason for the current phase of the pairing procedure.

enumerator gSmUnexpectedKeyset_c

The Responder upper layer is trying to distribute keys which were not requested during the pairing procedure or the peer device has sent a Key Distribution packet which was not expected.

enumerator gSmSmpTimeoutOccurred_c

An SMP timeout has occurred for the peer device. No more operations are accepted until a new physical link is established.

enumerator gSmUnknownSmpPacketType_c

An SMP packet with an unknown (or invalid) type has been received.

enumerator gSmInvalidSmpPacketLength_c

An SMP packet with an invalid length for the SMP packet type has been received.

enumerator gSmInvalidSmpPacketParameter_c

An SMP packet with an invalid parameter has been received.

enumerator gSmReceivedUnexpectedSmpPacket_c

An unexpected SMP packet was received.

enumerator gSmReceivedSmpPacketFromUnknownDevice_c

An SMP packet is received but the source Device ID cannot be identified.

enumerator gSmReceivedUnexpectedHciEvent_c

An HCI event has been received which cannot be handled by the SM or cannot be handled in the current context.

enumerator gSmReceivedHciEventFromUnknownDevice_c

An HCI event is received but the source Device ID cannot be identified.

enumerator gSmInvalidHciEventParameter_c

An HCI Event is received with an invalid parameter.

enumerator gSmLlConnectionEncryptionInProgress_c

A Link Layer Connection encryption was requested by the upper layer or attempted internally by the SM, but it could no be completed because an encryption was already

in progress. This situation could lead to an SMP Pairing Failure when the SM cannot encrypt the link with the STK. An unspecified pairing failure reason is used in this instance.

enumerator gSmLlConnectionEncryptionFailure_c

The Link Layer connection encryption procedure has failed.

enumerator gSmInsufficientResources_c

The SM could not allocate resources to perform operations (memory or timers).

enumerator gSmOobDataAddressMismatch_c

The address of the peer contained in the remote OOB data sent to the stack does not match the address used by the remote device for the connection/pairing procedure.

enumerator gSmSmpPacketReceivedAfterTimeoutOccurred_c

A SMP packet has been received from a peer device for which a pairing procedure has timed out. No further operations are permitted until a new connection is established.

enumerator gSmReceivedTimerEventForUnknownDevice_c

An Timer event is received but the source Device ID cannot be identified.

enumerator gSmUnattainableLocalDeviceSecRequirements_c

The provided pairing parameters cannot lead to a Pairing Procedure which satisfies the minimum security properties for the local device.

enumerator gSmUnattainableLocalDeviceMinKeySize_c

The provided pairing parameters cannot lead to a Pairing Procedure which satisfies the minimum encryption key size for the local device.

enumerator gSmUnattainablePeripheralSecReqRequirements_c

The provided pairing parameters cannot lead to a Pairing Procedure which satisfies the minimum security properties requested by the local device via an SMP Peripheral Security Request.

enumerator gSmInvalidPeerPublicKey_c

This status covers the case where the peer provides a public key with an identical X coordinate to our own.

enumerator gSmPairingErrorPasskeyEntryFailed_c

The passkey entry failed.

enumerator gSmPairingErrorConfirmValueFailed_c

The received random confirm value does not match the computed random confirm value.

enumerator gSmPairingErrorCommandNotSupported_c

The command is not supported.

enumerator gSmPairingErrorInvalidParameters_c

The command contains at least one invalid parameter.

enumerator gSmPairingErrorUnknownReason_c

Unknown pairing failure reason.

enumerator gSmPairingErrorTimeout_c

The pairing procedure timed out.

enumerator gSmPairingErrorAuthenticationRequirements_c

Authentication requirements were not met.

enumerator gSmPairingAlreadyStarted_c

The pairing process has already started.

enumerator gSmPairingErrorKeyRejected_c

The key was rejected.

enumerator gSmPairingErrorPairingNotSupported_c

Pairing is not supported by the device.

enumerator gSmPairingErrorEncryptionKeySize_c

The resultant encryption key size is not long enough for the security requirements of this device.

enumerator gSmPairingErrorDhKeyCheckFailed_c

DHKey Check value received doesn't match the one calculated by the local device.

enumerator gSmPairingErrorNumericComparisonFailed_c

Indicates that the confirm values in the numeric comparison protocol do not match.

enumerator gSmPairingErrorOobNotAvailable_c

Indicates that the OOB data is not available.

enumerator gSmPairingErrorRepeatedAttempts_c

Indicates that the pairing or authentication procedure is disallowed because too little time has elapsed since last pairing request or security request.

enumerator gSmPairingErrorBusy_c

Indicates that the device is not ready to perform a pairing procedure

enumerator gSmTbResolvableAddressDoesNotMatchIrk_c

The provided Resolvable Private Address and IRK do not match.

enumerator gSmTbInvalidDataSignature_c

The provided data signature does not match the computed data signature.

enumerator gSmKeySessionKeyDerivationFailed_c

The session key derivation failed.

enumerator gAttStatusBase_c

ATT status base.

enumerator gAttSuccess_c

Alias.

enumerator gGattStatusBase_c

GATT status base.

enumerator gGattSuccess_c

Alias.

enumerator gGattAnotherProcedureInProgress_c

Trying to start a GATT procedure while one is already in progress.

enumerator gGattLongAttributePacketsCorrupted_c

Writing a Long Characteristic failed because Prepare Write Request packets were corrupted.

enumerator gGattMultipleAttributesOverflow_c

Too many Characteristics are given for a Read Multiple Characteristic procedure.

enumerator gGattUnexpectedReadMultipleResponseLength_c

Read Multiple Characteristic procedure failed because unexpectedly long data was read.

enumerator gGattInvalidValueLength_c

An invalid value length was supplied to a Characteristic Read/Write operation.

enumerator gGattServerTimeout_c

No response was received from the Server.

enumerator gGattIndicationAlreadyInProgress_c

A Server Indication is already waiting for Client Confirmation.

enumerator gGattClientConfirmationTimeout_c

No Confirmation was received from the Client after a Server Indication.

enumerator gGattInvalidPduReceived_c

An invalid PDU length was received.

enumerator gGattPeerDisconnected_c

An ongoing GATT procedure could not be finished due to peer's disconnection.

enumerator gGattMtuExchangeInProgress_c

A Server Indication is already waiting for Client Confirmation.

enumerator gGattOutOfSyncProceduresOngoing_c

Client can't read the Database Hash until all pending procedures are done.

enumerator gGattConnectionSecurityRequirementsNotMet_c

Client cannot initiate communication if the device security requirements are not met, e.g., link is not yet encrypted/authenticated.

enumerator gGapStatusBase_c
GAP status base.

enumerator gGapSuccess_c
Alias.

enumerator gGapAdvDataTooLong_c
Trying to set too many bytes in the advertising payload.

enumerator gGapScanRspDataTooLong_c
Trying to set too many bytes in the scan response payload.

enumerator gGapDeviceNotBonded_c
Trying to execute an API that is only available for bonded devices.

enumerator gGapAnotherProcedureInProgress_c
Trying to start a GAP procedure while one is already in progress.

enumerator gDevDbStatusBase_c
DeviceDatabase status base.

enumerator gDevDbSuccess_c
Alias.

enumerator gDevDbCccdLimitReached_c
CCCD value cannot be saved because Server's CCCD list is full for the current client.

enumerator gDevDbCccdNotFound_c
CCCD with the given handle is not found in the Server's list for the current client.

enumerator gGattDbStatusBase_c
GATT Database status base.

enumerator gGattDbSuccess_c
Alias.

enumerator gGattDbInvalidHandle_c
An invalid handle was passed as parameter.

enumerator gGattDbCharacteristicNotFound_c
Characteristic was not found.

enumerator gGattDbCccdNotFound_c
CCCD was not found.

enumerator gGattDbServiceNotFound_c
Service Declaration was not found.

enumerator gGattDbDescriptorNotFound_c
Characteristic Descriptor was not found.

enumerator gGattDbServiceOrCharAlreadyDeclared_c
Service or characteristic already declared

enumerator gCsStatusBase_c
Channel Sounding status base.

enumerator gCsSuccess_c
Alias.

enumerator gCsCallbackAlreadyInstalled_c
The selected callback was already installed.

enumerator gCsSecurityCheckFail_c
GAP Mode 4 security check fail.

enum bearerStatus_tag
Enhanced ATT bearer status values
Values:

enumerator gEattBearerActive_c

enumerator gEattBearerReconfInProgress_c

enumerator gEattBearerSuspended_c

enumerator gEattBearerAllocated_c

enumerator gEattBearerFree_c

enumerator gEattBearerAlreadyAllocated_c

enum bleAdvertisingType_t
Advertising Type
Values:

enumerator gAdvConnectableUndirected_c
Answers to both connect and scan requests.

enumerator gAdvDirectedHighDutyCycle_c
Answers only to connect requests; smaller advertising interval for quicker connection.

enumerator gAdvScannable_c
Answers only to scan requests.

enumerator gAdvNonConnectable_c
Does not answer to connect nor scan requests.

enumerator gAdvDirectedLowDutyCycle_c
Answers only to connect requests; larger advertising interval.

enum bleAdvReportEventProperties_tag
Values:

enumerator gAdvEventConnectable_c
Connectable Advertisement

enumerator gAdvEventScannable_c
Scannable Advertisement

enumerator gAdvEventDirected_c
Directed Advertisement

enumerator gAdvEventScanResponse_c
Scan Response

enumerator gAdvEventLegacy_c
Legacy Advertisement PDU

enumerator gAdvEventAnonymous_c
Anonymous Advertisement

enum bleAdvRequestProperties_tag
Values:

enumerator gAdvReqConnectable_c
Connectable Advertising

enumerator gAdvReqScannable_c
Scannable Advertising

enumerator gAdvReqDirected_c
Directed Advertising

enumerator gAdvReqHighDutyCycle_c
High Duty Cycle

enumerator gAdvReqLegacy_c
Legacy Advertising PDU

enumerator gAdvReqAnonymous_c
Anonymous Advertising

enumerator gAdvIncludeTxPower_c
Set this option to include the Tx power in advertising packet.

enumerator gAdvUseDecisionPDU_c
Use ADV_DECISION_IND PDU(0b1001).

enumerator gAdvIncludeAdvAinDecisionPDU_c
Include AdvA in the extended header of all decision PDUs.

enumerator gAdvIncludeADIinDecisionPDU_c
Include ADI in the extended header of all decision PDUs.

enum bleAdvertisingFilterPolicy_t
Values:

enumerator gBleAdvFilterAllowScanFromAnyAllowConnFromAny_c
Filter Accept List is ignored.

enumerator gBleAdvFilterAllowScanFromWLAllowConnFromAny_c
Filter Accept List is used only for Scan Requests.

enumerator gBleAdvFilterAllowScanFromAnyAllowConnFromWL_c
Filter Accept List is used only for Connection Requests.

enumerator gBleAdvFilterAllowScanFromWLAllowConnFromWL_c
Filter Accept List is used for both Scan and Connection Requests.

enum bleLlConnectionRole_t
Values:

enumerator gBleLlConnectionCentral_c
Link Layer Central Role

enumerator gBleLlConnectionPeripheral_c
Link Layer Peripheral Role

enum bleCentralClockAccuracy_tag
Values:

enumerator gBleCentralClkAcc500ppm_c

enumerator gBleCentralClkAcc250ppm_c

enumerator gBleCentralClkAcc150ppm_c

enumerator gBleCentralClkAcc100ppm_c

enumerator gBleCentralClkAcc75ppm_c

enumerator gBleCentralClkAcc50ppm_c

enumerator gBleCentralClkAcc30ppm_c

enumerator gBleCentralClkAcc20ppm_c

enum bleAdvertiserClockAccuracy_tag

Values:

enumerator gBleAdvertiserClkAcc500ppm_c

enumerator gBleAdvertiserClkAcc250ppm_c

enumerator gBleAdvertiserClkAcc150ppm_c

enumerator gBleAdvertiserClkAcc100ppm_c

enumerator gBleAdvertiserClkAcc75ppm_c

enumerator gBleAdvertiserClkAcc50ppm_c

enumerator gBleAdvertiserClkAcc30ppm_c

enumerator gBleAdvertiserClkAcc20ppm_c

enum bleAdvertisingReportEventType_t

Values:

enumerator gBleAdvRepAdvInd_c

enumerator gBleAdvRepAdvDirectInd_c

enumerator gBleAdvRepAdvScanInd_c

enumerator gBleAdvRepAdvNonconnInd_c

enumerator gBleAdvRepScanRsp_c

enum hciPacketType_t

Values:

enumerator gHciCommandPacket_c

HCI Command

enumerator gHciDataPacket_c

L2CAP Data Packet

enumerator gHciSynchronousDataPacket_c
Not used in BLE

enumerator gHciEventPacket_c
HCI Event

enumerator gHciIsoDataPacket_c
HCI ISO data packet

enum bleScanType_t
Scanning type enumeration.
Values:

enumerator gScanTypePassive_c
Passive Scanning - advertising packets are immediately reported to the Host.

enumerator gScanTypeActive_c
Active Scanning - the scanner sends scan requests to the advertiser and reports to the Host after the scan response is received.

enum bleTransmitPowerLevelType_t
Values:

enumerator gReadCurrentTxPowerLevel_c
Current TX Power level.

enumerator gReadMaximumTxPowerLevel_c
Maximum recorded TX Power level.

enum bleTransmitPowerChannelType_t
Values:

enumerator gTxPowerAdvChannel_c
Advertising channel type when setting Tx Power.

enumerator gTxPowerConnChannel_c
Connection channel type when setting Tx Power.

enum bleChannelOverrideMode_t
Values:

enumerator gOverrideAdvChannels_c
Set the advertising channels

enumerator gOverrideScanChannels_c
Set the scanning channels

enumerator gOverrideInitChannels_c
Set the connection initiation channels

enum bleChannelFrequency_t

Values:

enumerator gBleFreq2402MHz_c

enumerator gBleFreq2404MHz_c

enumerator gBleFreq2406MHz_c

enumerator gBleFreq2408MHz_c

enumerator gBleFreq2410MHz_c

enumerator gBleFreq2412MHz_c

enumerator gBleFreq2414MHz_c

enumerator gBleFreq2416MHz_c

enumerator gBleFreq2418MHz_c

enumerator gBleFreq2420MHz_c

enumerator gBleFreq2422MHz_c

enumerator gBleFreq2424MHz_c

enumerator gBleFreq2426MHz_c

enumerator gBleFreq2428MHz_c

enumerator gBleFreq2430MHz_c

enumerator gBleFreq2432MHz_c

enumerator gBleFreq2434MHz_c

enumerator gBleFreq2436MHz_c

enumerator gBleFreq2438MHz_c

enumerator gBleFreq2440MHz_c

enumerator gBleFreq2442MHz_c

enumerator gBleFreq2444MHz_c

enumerator gBleFreq2446MHz_c

enumerator gBleFreq2448MHz_c

enumerator gBleFreq2450MHz_c

enumerator gBleFreq2452MHz_c

enumerator gBleFreq2454MHz_c

enumerator gBleFreq2456MHz_c

enumerator gBleFreq2458MHz_c

enumerator gBleFreq2460MHz_c

enumerator gBleFreq2462MHz_c

enumerator gBleFreq2464MHz_c

enumerator gBleFreq2466MHz_c

enumerator gBleFreq2468MHz_c

enumerator gBleFreq2470MHz_c

enumerator gBleFreq2472MHz_c

enumerator gBleFreq2474MHz_c

enumerator gBleFreq2476MHz_c

enumerator gBleFreq2478MHz_c

enumerator gBleFreq2480MHz_c

enum bleTxTestPacketPayload_t

Values:

enumerator gBleTestPacketPayloadPrbs9_c

enumerator gBleTestPacketPayloadPattern11110000_c

enumerator gBleTestPacketPayloadPattern10101010_c

enumerator gBleTestPacketPayloadPrbs15_c

enumerator gBleTestPacketPayloadPatternAllBits1_c

enumerator gBleTestPacketPayloadPatternAllBits0_c

enumerator gBleTestPacketPayloadPattern00001111_c

enumerator gBleTestPacketPayloadPattern01010101_c

enum bleHardwareErrorCode_t

Values:

enumerator bleHwErrCodeNoError_c

enum leSupportedFeatures_tag

Values:

enumerator gLeEncryption_c

enumerator gLeConnectionParametersRequestProcedure_c

enumerator gLeExtendedRejectIndication_c

enumerator gLePeripheralInitiatedFeaturesExchange_c

enumerator gLePing_c

enumerator gLeDataPacketLengthExtension_c

enumerator gLeLlPrivacy_c

enumerator gLeExtendedScannerFilterPolicies_c

enumerator gLe2MbPhy_c

enumerator gLeStableModulationIdxTx_c

enumerator gLeStableModulationIdxRx_c

enumerator gLeCodedPhy_c

enumerator gLeExtendedAdv_c

enumerator gLePeriodicAdv_c

enumerator gLeChannelSelAlg2_c

enumerator gLePowerClass1_c

enumerator gLeMinNumOfUsedChanProcedure_c

enumerator gLePeriodicAdvSyncTransferSender_c

enumerator gLePeriodicAdvSyncTransferReceiver_c

enumerator gLePowerControlRequest1_c

enumerator gLePowerControlRequest2_c

enumerator gLePathLossMonitoring_c

enumerator gAdvertisingCodingSelection_c

enumerator gAdvertisingCodingSelectionHostSupport_c

enumerator gLePawrAdvertiser_c

enumerator gLePawrScanner_c

enum gapGenericEventType_t

Generic Event Type

Values:

enumerator gInitializationComplete_c

Initial setup started by Ble_HostInitialize is complete.

enumerator gInternalError_c

An internal error occurred.

enumerator gAdvertisingSetupFailed_c

Error during advertising setup.

enumerator gAdvertisingParametersSetupComplete_c

Advertising parameters have been successfully set. Response to Gap_SetAdvertisingParameters.

enumerator gAdvertisingDataSetupComplete_c

Advertising and/or scan response data has been successfully set. Response to Gap_SetAdvertisingData.

enumerator gFilterAcceptListSizeRead_c

Contains the Filter Accept List size. Response to Gap_ReadFilterAcceptListSize.

enumerator gDeviceAddedToFilterAcceptList_c

Device has been added to Filter Accept List. Response to Gap_AddDeviceToFilterAcceptList.

enumerator gDeviceRemovedFromFilterAcceptList_c

Device has been removed from the Filter Accept List. Response to Gap_RemoveDeviceFromFilterAcceptList.

enumerator gFilterAcceptListCleared_c

Filter Accept List has been cleared. Response to Gap_ClearFilterAcceptList.

enumerator gRandomAddressReady_c

A random device address has been created. Response to Gap_CreateRandomDeviceAddress.

enumerator gCreateConnectionCanceled_c

Connection initiation was successfully cancelled. Response to Gap_CancelInitiatingConnection.

enumerator gPublicAddressRead_c

Contains the public device address. Response to Gap_ReadPublicDeviceAddress.

enumerator gAdvTxPowerLevelRead_c

Contains the TX power on the advertising channel. Response to Gap_ReadAdvertisingTxPowerLevel.

enumerator gPrivateResolvableAddressVerified_c

Contains the result of PRA verification. Response to Gap_VerifyPrivateResolvableAddress.

enumerator gRandomAddressSet_c

Random address has been set into the Controller. Response to Gap_SetRandomAddress.

enumerator gLeScPublicKeyRegenerated_c

The private/public key pair used for LE Secure Connections pairing has been regenerated.

enumerator gLeScLocalOobData_c

Local OOB data used for LE Secure Connections pairing.

enumerator gHostPrivacyStateChanged_c

Host Privacy was enabled or disabled.

enumerator gControllerPrivacyStateChanged_c

Controller Privacy was enabled or disabled.

enumerator gControllerTestEvent_c
Controller Test was started or stopped.

enumerator gTxPowerLevelSetComplete_c
Controller Tx Power Level set complete or invalid.

enumerator gLePhyEvent_c
Phy Mode of a connection has been updated by the Controller.

enumerator gControllerNotificationEvent_c
Controller Enhanced Notification received.

enumerator gGetConnParamsComplete_c
Get Connection Parameters command complete

enumerator gBondCreatedEvent_c
Bond Created Event signalling the stack created a bond after pairing or at app request.

enumerator gChannelMapSet_c
Channel map set complete in the Controller.

enumerator gExtAdvertisingParametersSetupComplete_c
Extended advertising parameters have been successfully set.

enumerator gExtAdvertisingDataSetupComplete_c
Extended advertising data has been successfully set.

enumerator gExtAdvertisingSetRemoveComplete_c
An advertising set has been removed from the Controller.

enumerator gPeriodicAdvParamSetupComplete_c
Periodic advertising parameters have been successfully set.

enumerator gPeriodicAdvDataSetupComplete_c
Periodic advertising data have been successfully set.

enumerator gPeriodicAdvertisingStateChanged_c
Event received when periodic advertising has been successfully enabled or disabled.

enumerator gPeriodicAdvListUpdateComplete_c
Periodic advertiser list has been successfully updated.

enumerator gPeriodicAdvCreateSyncCancelled_c
Periodic advertising create sync command was successfully cancelled

enumerator gTxEntryAvailable_c
This event is generated when a TX entry becomes available after they were all in use.

enumerator gControllerLocalRPARead_c

Contains the resolvable private device address. Response to Gap_ReadControllerLocalRPA.

enumerator gConnectionlessCteTransmitParamsSetupComplete_c

Connectionless CTE transmit parameters have been successfully set.

enumerator gConnectionlessCteTransmitStateChanged_c

Connectionless CTE for an advertising set was enabled or disabled.

enumerator gConnectionlessIqSamplingStateChanged_c

Connectionless CTE IQ sampling for an advertising train was enabled or disabled.

enumerator gAntennaInformationRead_c

Antenna information was read from the controller.

enumerator gModifiedSleepClockAccuracy_c

The Sleep Clock accuracy was changed

enumerator gPeriodicAdvRecvEnableComplete_c

Enable or disable reports for the periodic advertising train command is complete

enumerator gPeriodicAdvSyncTransferComplete_c

The command used to instruct the Controller to send synchronization information about the periodic advertising train identified by the Sync_Handle parameter to a connected device is complete

enumerator gPeriodicAdvSetInfoTransferComplete_c

The command used to instruct the Controller to send synchronization information about the periodic advertising in an advertising set to a connected device is complete

enumerator gSetPeriodicAdvSyncTransferParamsComplete_c

The command specifying how the Controller will process periodic advertising synchronization information is complete

enumerator gSetDefaultPeriodicAdvSyncTransferParamsComplete_c

The command which set the default parameters for periodic advertising synchronization information is complete

enumerator gPeriodicAdvSyncTransferSucceeded_c

Event received when Controller has succeeded the Synchronization to the periodic advertising train

enumerator gPeriodicAdvSyncTransferFailed_c

Event received when Controller has failed the Synchronization to the periodic advertising train

enumerator gConnEvtLeGenerateDhKeyComplete_c

DHKey generation is complete. Key can be found in gapConnectionEvent_t.eventData.leGenerateDhKeyCompleteEvent

enumerator gHandoverGetComplete_c
Handover data get complete.

enumerator gHandoverSetComplete_c
Handover data set complete.

enumerator gHandoverGetCsLlContextComplete_c
Handover CS LL context data get complete.

enumerator gHandoverSetCsLlContextComplete_c
Handover CS LL context data set complete.

enumerator gHandoverGetTime_c
Handover Get Time command complete

enumerator gHandoverSuspendTransmitComplete_c
Handover Suspend Transmit command complete

enumerator gHandoverResumeTransmitComplete_c
Handover Resume Transmit command complete

enumerator gHandoverAnchorNotificationStateChanged_c
Handover Anchor Notification command complete

enumerator gHandoverAnchorSearchStarted_c
Handover Anchor Search Start command complete

enumerator gHandoverAnchorSearchStopped_c
Handover Anchor Search Stop command complete

enumerator gHandoverTimeSyncTransmitStateChanged_c
Handover Time Sync Transmit command complete

enumerator gHandoverTimeSyncReceiveComplete_c
Handover Time Sync Receive command complete

enumerator gHandoverAnchorMonitorEvent_c
Event received from Controller - Handover Anchor Monitor

enumerator gHandoverTimeSyncEvent_c
Event received from Controller - Handover Time Sync

enumerator gHandoverConnParamUpdateEvent_c
Event received from Controller - Handover Conn Params Update

enumerator gRemoteVersionInformationRead_c
Version Information of a peer was read

enumerator gLlSkdReportEvent_c

Session Key Diversifier report

enumerator gLeSetSchedulerPriorityComplete_c

LE Set Scheduler Priority command complete

enumerator gDeInitializationComplete_c

Event received when Ble_HostDeInitialize is complete.

enumerator gHandoverAnchorMonitorPacketEvent_c

Event received from Controller - Handover Anchor Monitor Packet. pPdu must be freed by the application

enumerator gHandoverAnchorMonitorPacketContinueEvent_c

Event received from Controller - Handover Anchor Monitor Packet Continue. pPdu must be freed by the application

enumerator gHandoverFreeComplete_c

Handover data free complete.

enumerator gHandoverUpdateConnParamsComplete_c

Handover Update Connection Parameters command complete

enumerator gExtAdvertisingDecisionDataSetupComplete_c

Extended advertising decision data has been successfully set.

enumerator gDecisionInstructionsSetupComplete_c

decision instructions used when listening for decision advertisements PDUs has been successfully set.

enumerator gHandoverLlPendingData_c

ACL Data pending to be transmited by the LL

enumerator gLeChannelOverrideComplete_c

LE Channel Override command complete

enumerator gPeriodicAdvSetSubeventDataComplete_c

Periodic advertising subevent data has been successfully set.

enumerator gPeriodicAdvSetResponseDataComplete_c

Periodic advertising response data has been successfully set.

enumerator gPeriodicSyncSubeventComplete_c

Set Sync Subevent command successfully completed.

enumerator gHandoverConnectionUpdateProcedureEvent_c

This event is used to report the new connection parameters indicated during the Connection Update procedure

enumerator gHandoverApplyConnectionUpdateProcedureComplete_c

This event is used to report the new connection parameters indicated during the Connection Update procedure

enumerator gVendorUnitaryTestComplete_c

Vendor Unitary Test command complete

enumerator gLeSetDataRelatedAddressChangesComplete_c

Set Data Related Address Changes command complete

enum gapInternalErrorSource_t

Internal Error Source - the command that triggered the error

Values:

enumerator gHciCommandStatus_c

enumerator gCheckPrivateResolvableAddress_c

enumerator gVerifySignature_c

enumerator gAddNewConnection_c

enumerator gResetController_c

enumerator gSetEventMask_c

enumerator gReadLeBufferSize_c

An error occurred during the Set Data Related Address procedure

enum gapControllerTestEventType_t

Controller Test Event Type

Values:

enumerator gControllerReceiverTestStarted_c

enumerator gControllerTransmitterTestStarted_c

enumerator gControllerTestEnded_c

enum gapLeAllPhyFlags_t

Le All Phys Preferences flags.

Values:

enumerator gLeTxPhyNoPreference_c

Host has no preference for Tx Phy

enumerator gLeRxPhyNoPreference_c

Host has no preference for Rx Phy

enum gapLePhyOptionsFlags_t

Le Phys Options Preferences flags.

Values:

enumerator gLeCodingNoPreference_c

Host has no preference on the LE Coded Phy

enumerator gLeCodingS2_c

Host prefers to use S=2 on the LE Coded Phy

enumerator gLeCodingS8_c

Host prefers to use S=8 on the LE Coded Phy

enumerator gLeCodingS2Req_c

Host requires to use S=2 on the LE Coded Phy

enumerator gLeCodingS8Req_c

Host requires to use S=8 on the LE Coded Phy

enum gapLePhyMode_tag

Values:

enumerator gLePhy1M_c

Tx/Rx Phy on the connection is LE 1M

enumerator gLePhy2M_c

Tx/Rx Phy on the connection is LE 2M

enumerator gLePhyCoded_c
Tx/Rx Phy on the connection is LE Coded

enum gapPhyEventType_t
Phy Event Type
Values:

enumerator gPhySetDefaultComplete_c
Gap_LeSetPhy default mode was successful

enumerator gPhyRead_c
Gap_LeReadPhy return values

enumerator gPhyUpdateComplete_c
Gap_LeSetPhy return values for a connection or an update occurred

enum bleNotificationEventType_tag
Values:

enumerator gNotifEventNone_c
No enhanced notification event enabled

enumerator gNotifConnEventOver_c
Connection event over

enumerator gNotifConnRxPdu_c
Connection Rx PDU

enumerator gNotifAdvEventOver_c
Advertising event over

enumerator gNotifAdvTx_c
Advertising ADV transmitted

enumerator gNotifAdvScanReqRx_c
Advertising SCAN REQ Rx

enumerator gNotifAdvConnReqRx_c
Advertising CONN REQ Rx

enumerator gNotifScanEventOver_c
Scanning event over

enumerator gNotifScanAdvPktRx_c
Scanning ADV PKT Rx

enumerator gNotifScanRspRx_c
Scanning SCAN RSP Rx

enumerator gNotifScanReqTx_c
Scanning SCAN REQ Tx

enumerator gNotifConnCreated_c
Connection created

enumerator gNotifChannelMatrix_c
Enable channel status monitoring (KW37 only)

enumerator gNotifPhyReq_c
Phy Req Pdu ack received (KW37 only)

enumerator gNotifConnChannelMapUpdate_c
Channel map update

enumerator gNotifConnInd_c
Connect indication

enumerator gNotifPhyUpdateInd_c
Phy update indication

enum bleCteTransmitEnable_t
Values:

enumerator gCteTransmitDisable_c

enumerator gCteTransmitEnable_c

enum bleIqSamplingEnable_t
Values:

enumerator gIqSamplingDisable_c

enumerator gIqSamplingEnable_c

enum bleCteReqEnable_t
Values:

enumerator gCteReqDisable_c

enumerator gCteReqEnable_c

enum bleCteRspEnable_t
Values:

enumerator gCteRspDisable_c

enumerator gCteRspEnable_c

enum bleCteType_tag

Values:

enumerator gCteTypeAoA_c

AoA Constant Tone Extension

enumerator gCteTypeAoD1us_c

AoD Constant Tone Extension with 1 microsecond slots

enumerator gCteTypeAoD2us_c

AoD Constant Tone Extension with 2 microsecond slots

enumerator gCteTypeNoCte_c

No Constant Tone Extension

enum bleSlotDurations_tag

Values:

enumerator gSlotDurations1us_c

Switching and sampling slot durations are 1 microsecond each

enumerator gSlotDurations2us_c

Switching and sampling slot durations are 2 microseconds each

enum bleIqReportPacketStatus_tag

Values:

enumerator gIqReportPacketStatusCorrectCrc_c

CRC was correct

enumerator gIqReportPacketStatusCrcIncorrectUsedLength_c

CRC was incorrect and the Length and CTETime fields of the packet were used to determine sampling points

enumerator gIqReportPacketStatusCrcIncorrectUsedOther_c

CRC was incorrect but the Controller has determined the position and length of the Constant Tone Extension in some other way

enumerator gIqReportPacketStatusInsufficientResources_c

Insufficient resources to sample (Channel_Index, CTE_Type, and Slot_Durations invalid).

enum blePathLossThresholdZoneEntered_tag

Values:

enumerator gPathLossThresholdLowZone_c

Entered low zone.

enumerator gPathLossThresholdMiddleZone_c
Entered middle zone.

enumerator gPathLossThresholdHighZone_c
Entered high zone.

enum bleTxPowerReportingReason_tag
Values:

enumerator gLocalTxPowerChanged_c
Local transmit power changed.

enumerator gRemoteTxPowerChanged_c
Remote transmit power changed.

enumerator gReadRemoteTxPowerLevelCommandCompleted_c
HCI_LE_Read_Remote_Transmit_Power_Level command completed.

enum blePowerControlPhyType_tag
Values:

enumerator gPowerControlLePhy1M_c
LE 1M Phy.

enumerator gPowerControlLePhy2M_c
LE 2M Phy.

enumerator gPowerControlLePhyCodedS8_c
LE Coded Phy with S=8 data coding.

enumerator gPowerControlLePhyCodedS2_c
LE Coded Phy with S=2 data coding.

enum blePathLossReportingEnable_t
Values:

enumerator gPathLossReportingDisable_c

enumerator gPathLossReportingEnable_c

enum bleTxPowerReportingEnable_t
Values:

enumerator gTxPowerReportingDisable_c

enumerator gTxPowerReportingEnable_c

enum bleHandoverSuspendTransmitMode_t

Values:

enumerator gDoNotUseEventCounter_c

enumerator gUseEventCounter_c

enumerator gSafeStopLlTx_c

enumerator gSafeStopHostLlTx_c

enum bleHandoverAnchorSearchMode_t

Values:

enumerator gSuspendTxMode_c

enumerator gRssiSniffingMode_c

enumerator gPacketMode_c

enum bleGetConnParamsMode_t

Values:

enumerator gSendEventAfterRemoteSNChange_c

enumerator gSendEventAfterLLProcUpdate_c

enum bleHandoverAnchorNotificationEnable_t

Values:

enumerator gAnchorNotificationDisable_c

enumerator gAnchorNotificationEnable_c

enum bleHandoverTimeSyncEnable_t

Values:

enumerator gTimeSyncDisable_c

enumerator gTimeSyncEnable_c

enum bleHandoverTimeSyncStopWhenFound_t

Values:

enumerator gTimeSyncDoNotStopWhenFound_c

enumerator gTimeSyncStopWhenFound_c

enum bleAdvIndexType_t

Values:

enumerator gAdvIndexAscend_c

enumerator gAdvIndexDescend_c

enumerator gAdvIndexUser_c

enumerator gAdvIndexRandom_c

typedef enum *bleResult_tag* bleResult_t

BLE result type - the return value of BLE API functions

typedef uint8_t deviceId_t

Unique identifier type for a connected device.

typedef uint8_t bearerId_t

ATT bearer identifier.

typedef enum *bearerStatus_tag* bearerStatus_t

Enhanced ATT bearer status values

typedef uint8_t bleAddressType_t

Bluetooth Device Address Type - Size: 1 Octet, Range: [gBleAddrTypePublic_c:gBleAddrTypeRandom_c]

typedef uint8_t bleDeviceAddress_t[(6U)]

Bluetooth Device Address - array of 6 bytes.

typedef uint8_t bleUuidType_t

Bluetooth UUID type - values chosen to correspond with the ATT UUID format

typedef uint16_t bleAdvReportEventProperties_t

Advertising Event properties

typedef uint16_t bleAdvRequestProperties_t

Advertising Request properties

typedef uint8_t bleCentralClockAccuracy_t

typedef uint8_t bleAdvertiserClockAccuracy_t

typedef uint8_t bleScanningFilterPolicy_t

Scanning filter policy enumeration - Size: 1 Octet, Range: [gScanAll_c:gScanWithFilterAcceptList_c]

typedef uint8_t bleInitiatorFilterPolicy_t

Initiator filter policy enumeration - Size: 1 Octet, Range: [gUseDeviceAddress_c:gUseFilterAcceptList_c]

typedef uint8_t blePrivacyMode_t

Privacy Mode enumeration - Size: 1 Octet, Range: [gNetworkPrivacy_c:gDevicePrivacy_c]

typedef uint8_t bleChannelMap_t[(5U)]

Bluetooth Channel map - array of 5 bytes.

typedef uint64_t leSupportedFeatures_t

typedef uint8_t gapLePhyFlags_t

Le Tx/Rx Phys Preferences flags.

typedef uint8_t gapLePhyMode_t

Le Tx/Rx Phys.

typedef uint16_t bleNotificationEventType_t

Controller Enhanced Notification Event Type

typedef struct *bleBondCreatedEvent_tag* bleBondCreatedEvent_t

Bond Created Event

typedef struct *gapAddrReadyEvent_t_tag* gapAddrReadyEvent_t

Address Ready Event

typedef struct *bleAntennaInformation_tag* bleAntennaInformation_t

Antenna Information Read Event

const uint16_t gcConnectionEventMinDefault_c

const uint16_t gcConnectionEventMaxDefault_c

const uint8_t gBleEattMaxConnectionChannels

const uint16_t gBleEattPsmMtu

const uint8_t gMaxAdvReportQueueSize

const bool_t gUseHciCommandFlowControl

Enables/Disables Hci Command Flow Control if the host lib supports this feature

messaging_t gApp2Host_TaskQueue

App to Host message queue for the Host Task

messaging_t gHci2Host_TaskQueue

HCI to Host message queue for the Host Task

bleResult_t Ble_HostInitialize(*gapGenericCallback_t* genericCallback, *hciHostToControllerInterface_t* hostToControllerInterface)

Performs initialization of the BLE Host stack.

Remark

Application must wait for the gInitializationComplete_c generic event.

Parameters

- genericCallback – **[in]** Callback used to propagate GAP generic events to the application.
- hostToControllerInterface – **[in]** LE Controller uplink interface function pointer

Returns
gBleSuccess_c or error.

bleResult_t Ble_HostDeInitialize(void)
performs De-Initialize the Bluetooth LE Host

Remark

Application must wait for the gDeInitializationComplete_c generic event.

Parameters

- none –

Return values
gBleSuccess_c – or error.

bleResult_t Ble_HciRecv(*hciPacketType_t* packetType, void *pHciPacket, uint16_t packetSize)
This is the BLE Host downlink interface function.

Remark

This function must be registered as a callback by the LE Controller and called to send HCI packets (events and LE-U data) to the BLE Host.

Parameters

- packetType – **[in]** The type of the packet sent by the LE Controller
- pHciPacket – **[in]** Pointer to the packet sent by the LE Controller
- packetSize – **[in]** Number of bytes sent by the LE Controller

Returns
gBleSuccess_c or gBleOutOfMemory_c

bleResult_t Ble_HciRecvFromIsr(*hciPacketType_t* packetType, void *pHciPacket, uint16_t packetSize)
This is the BLE Host downlink interface function to be used in ISR context.

Remark

This function must be registered as a callback by the HCI Transport layer and called to send HCI packets from the controller (events and LE-U data) to the BLE Host.

Parameters

- packetType – **[in]** The type of the packet sent by the LE Controller
- pHciPacket – **[in]** Pointer to the packet sent by the LE Controller
- packetSize – **[in]** Number of bytes sent by the LE Controller

Returns
gBleSuccess_c or gBleOutOfMemory_c

bool_t Ble_CheckMemoryStorage(void)
This function performs runtime checks to determine whether memory storage is properly configured for the application settings.

Returns
True if memory is configured correctly False otherwise.

OSA_EVENT_HANDLE_DEFINE (gHost_TaskEvent)
Event for the Host Task Queue

void Host_TaskHandler(void *args)
Contains the Host Task logic.

Remark

This function must be called exclusively by the Host Task code from the application.

---

gMaxAdvSets_c

gInvalidDeviceId_c

gInvalidNvmIndex_c

gcConnectionIntervalMin_c
Boundary values for the Connection Parameters (Standard GAP).

gcConnectionIntervalMax_c

gcConnectionPeripheralLatencyMax_c

gcConnectionSupervisionTimeoutMin_c

gcConnectionSupervisionTimeoutMax_c

gcConnectionIntervalMinDefault_c
Default values for the Connection Parameters (Preferred).

connIntervalmin = Conn_Interval_Min * 1.25 ms

Value of 0xFFFF indicates no specific minimum.

gcConnectionIntervalMaxDefault_c
connIntervalmax = Conn_Interval_Max * 1.25 ms

Value of 0xFFFF indicates no specific maximum.

gcConnectionPeripheralLatencyDefault_c

gcConnectionSupervisionTimeoutDefault_c

Time = N * 10 ms

STATIC

When unit testing is performed, access from unit test module to static functions/variables within the tested module is not possible and therefore the static storage class identifier shall be removed

gBleAddrTypePublic_c

Bluetooth Device Address Types Public Device Address - fixed into the Controller by the manufacturer.

gBleAddrTypeRandom_c

Random Device Address - set by the Host into the Controller for privacy reasons.

Ble_IsPrivateResolvableDeviceAddress(bleAddress)

PRA condition: check the 6th byte - MSB should be 0; 2nd MSB should be 1.

Ble_IsPrivateNonresolvableDeviceAddress(bleAddress)

PNRA condition: check the 6th byte - MSB should be 0; 2nd MSB should be 0.

Ble_IsRandomStaticDeviceAddress(bleAddress)

RSA condition: check the 6th byte - MSB should be 1; 2nd MSB should be 1.

Ble_DeviceAddressesMatch(bleAddress1, bleAddress2)

A macro used to compare two device addresses

Ble_CopyDeviceAddress(destinationAddress, sourceAddress)

A macro used to copy device addresses

gBleUuidType16_c

16-bit standard UUID

gBleUuidType128_c

128-bit long/custom UUID

gBleUuidType32_c

32-bit UUID - not available as ATT UUID format

gLePhy1MFlag_c

Host prefers to use LE 1M Tx/Rx Phy, possibly among others

gLePhy2MFlag_c

Host prefers to use LE 2M Tx/Rx Phy, possibly among others

gLePhyCodedFlag_c

Host prefers to use LE Coded Tx/Rx Phy, possibly among others

gAdvDataChange_c

Advertising Data Change reason

gScanRspDataChange_c

Scan Response Data Change reason

gUseDeviceAddress_c

Initiator filter policy values Initiates a connection with a specific device identified by its address.

gUseFilterAcceptList_c

Initiates connections with all the devices in the Filter Accept List at the same time.

gUseDeviceAddressNoDecisionPDUs_c

Initiator filter policy values extended for gBLE60_DecisionBasedAdvertisingFilteringSupport_d == TRUE Filter Accept List is not used to determine which advertiser to connect to. Decision PDUs shall be ignored. Peer_Address_Type and Peer_Address shall be used.

gUseFilterAcceptListNoDecisionPDUs_c

Filter Accept List is used to determine which advertiser to connect to. Decision PDUs shall be ignored. Peer_Address_Type and Peer_Address shall be ignored.

gUseOnlyDecisionPDUs_c

Filter Accept List is not used to determine which advertiser to connect to. Only Decision PDUs shall be processed. Peer_Address_Type and Peer_Address shall be ignored.

gUseFilterAcceptListAllPDUs_c

Filter Accept List is used to determine which advertiser to connect to. All PDUs shall be processed. Peer_Address_Type and Peer_Address shall be ignored.

gUseDecisionPDU_UseFilterAcceptListForOtherPDUs_c

All decision PDUs shall be processed. Filter Accept List is used to determine which other PDUs to process. Peer_Address_Type and Peer_Address shall be ignored.

gScanAll_c

Basic Scanning filter policy values. Kept for apps backward compatibility Basic unfiltered scanning filter policy.

gScanWithFilterAcceptList_c

Basic filtered scanning filter policy (using the Filter Accept List).

gBasicUnfilteredScan_c

Scanning filter policy values. Basic unfiltered scanning filter policy.

gBasicFilteredScan_c

Basic filtered scanning filter policy (using the Filter Accept List).

gExtendedUnfilteredScan_c

Extended unfiltered scanning filter policy.

gExtendedFilteredScan_c

Extended filtered scanning filter policy(using the Filter Accept List).

gScanOnlyNonDecisionPDUs_c

PDU Scanning filter policy values. To be used in bitwise OR operations with scanning filter policy above only with gBLE60_DecisionBasedAdvertisingFilteringSupport_d == TRUE e.g. ((uint8_t)(gExtendedUnfilteredScan_c | gScanAllPDUs_c)) Scan Only Non Decision Advertising PDU.

gScanAllPDUs_c

Scan Decision and Non Decision Advertising PDU.

gScanOnlyDecisionPDUs_c

Scan Only Decision Advertising PDU.

gNetworkPrivacy_c

Privacy mode values Use Network Privacy Mode for the peer device (default)

gDevicePrivacy_c

Use Device Privacy Mode for the peer device

gUnenhancedBearerId_c

bearer id 0 is used for the Unenhanced ATT bearer

gDHKeySize_c

LE Secure Connections 256 bit DHKey

gSkdSize_c

LL Session Key Diversfier size

LL_PHY_1M

LL_PHY_2M

LL_PHY_S8

LL_PHY_S2

gVendorHandoverMaxCsLlContextSize_c

Maximum size of the LL Context for Handover (CS context is largest)

gVendorUnitaryTestSize_c

Maximum size of the VENDOR_UNITARY_TEST response

gBleSig_PrimaryService_d

Bluetooth SIG UUID constants for GATT declarations

Primary Service declaration UUID

gBleSig_SecondaryService_d

Secondary Service declaration UUID

gBleSig_Include_d
: Include declaration UUID

gBleSig_Characteristic_d
: Characteristic declaration UUID

gBleSig_CharExtendedProperties_d
: Characteristic Extended Properties UUID

: Boot Keyboard Input Report UUID

gBleSig_BootKeyboardOutputReport_d
: Boot Keyboard output Report UUID

gBleSig_BootMouseInputReport_d
: Boot Mouse Input Report UUID

gBleSig_GlucoseMeasurementContext_d
: Glucose Measurement Context Characteristic UUID

gBleSig_BpMeasurement_d
: Blood Pressure Measurement UUID

gBleSig_BpEnhancedMeasurement_d
: Blood Pressure Enhanced Measurement UUID

gBleSig_BpRecord_d
: Blood Pressure Record UUID

gBleSig_IntermediateCuffPressure_d
: Intermediate Cuff Pressure UUID

gBleSig_HrMeasurement_d
: Heart Rate Measurement UUID

gBleSig_BodySensorLocation_d
: Body Sensor Location UUID

gBleSig_HrControlPoint_d
: Heart Rate Control Point UUID

gBleSig_AlertStatus_d
: Alert Status UUID

gBleSig_RingerControlPoint_d
: Ringer Control Point UUID

gBleSig_RingerSetting_d
: Ringer Setting UUID

gBleSig_AlertNotifControlPoint_d
: Alert Notif Control Point UUID

gBleSig_UnreadAlertStatus_d
: Unread Alert Status UUID

gBleSig_NewAlert_d
: New Alert UUID

gBleSig_SupportedNewAlertCategory_d
: Supported New Alert Category UUID

gBleSig_SupportedUnreadAlertCategory_d
: Supported Unread Alert Category UUID

gBleSig_BloodPressureFeature_d
: Blood Pressure Feature UUID

gBleSig_HidInformation_d
: HID Information UUID

gBleSig_HidBootMouseInputReport_d
: HID Boot Mouse Input Report UUID

gBleSig_HidCtrlPoint_d
: HID Control Point UUID

gBleSig_Report_d
: Report UUID

gBleSig_ProtocolMode_d
: Protocol Mode UUID

gBleSig_ScanIntervalWindow_d
: Scan Interval Window UUID

gBleSig_PnpId_d
: PnP Id UUID

gBleSig_GlucoseFeature_d
: Glucose Feature Characteristic UUID

gBleSig_RaCtrlPoint_d
: Record Access Ctrl Point Characteristic UUID

gBleSig_RscMeasurement_d
: RSC Measurement UUID

gBleSig_RscFeature_d
: RSC Feature UUID

gBleSig_ScControlPoint_d
: SC Control Point UUID

gBleSig_CscMeasurement_d
: CSC Measurement Characteristic UUID

gBleSig_CscFeature_d
: CSC Feature Characteristic UUID

gBleSig_SensorLocation_d
: Sensor Location Characteristic UUID

gBleSig_PlxSCMeasurement_d
: PLX Spot-Check Measurement Characteristic UUID

gBleSig_PlxContMeasurement_d
: PLX Continuous Measurement Characteristic UUID

gBleSig_PulseOximeterFeature_d
: PLX Feature Characteristic UUID

gBleSig_CpMeasurement_d
: CP Measurement Characteristic UUID

gBleSig_CpVector_d
: CP Measurement Vector UUID

gBleSig_CpFeature_d
: CP Feature CharacteristicUUID

gBleSig_CpControlPoint_d
: CP Control Point UUID

gBleSig_LocationAndSpeed_d
: Location and Speed Characteristic UUID

gBleSig_Navigation_d
: Navigation Characteristic UUID

gBleSig_PositionQuality_d
: Position Quality Characteristic UUID

gBleSig_LnFeature_d
: LN Feature Characteristic UUID

gBleSig_LnControlPoint_d
: LN Control Point Characteristic UUID

gBleSig_Temperature_d
: Temperature Characteristic UUID

gBleSig_CentralAddressResolution_d
: Central Address Resolution Characteristic UUID

gBleSig_URI_d
: URI Characteristic UUID

gBleSig_HTTP_Headers_d
: HTTP Headers Characteristic UUID

gBleSig_HTTP_StatusCode_d
: HTTP Status Code Characteristic UUID

gBleSig_HTTP_EntityBody_d
: HTTP Entity Body Characteristic UUID

gBleSig_HTTP_ControlPoint_d
: HTTP Control Point Characteristic UUID

gBleSig_HTTPS_Security_d
: HTTPS Security Characteristic UUID

gBleSig_ResolvablePrivateAddressOnly_d
: Resolvable Private Address Only Characteristic UUID

gBleSig_MeshProvisioningService_d
: BLE Mesh Provisioning Service UUID

gBleSig_MeshProxyService_d
: BLE Mesh Proxy Service UUID

gBleSig_MeshProvDataIn_d
: BLE Mesh Prov Data In Char UUID

gBleSig_MeshProvDataOut_d
: BLE Mesh Prov Data Out Char UUID

gBleSig_MeshProxyDataIn_d
: BLE Mesh Proxy Data In Char UUID

gBleSig_MeshProxyDataOut_d
: BLE Mesh Proxy Data Out Char UUID

gBleSig_GattSecurityLevels_d
: LE GATT Security Levels characteristic UUID

gBleSig_EncryptedDataKeyMaterial_d
: Encrypted Data Key Material characteristic UUID

gBleSig_CAR_NotSupported_d
: Central Address Resolution Characteristic Values

gBleSig_CAR_Supported_d

gBleSig_RPAO_Used_d
: Resolvable Private Address Only Characteristic Values

gBleSig_RangingService_d
: Ranging Service UUID

gBleSig_RasFeature_d
: RAS Feature Characteristic UUID

gBleSig_RasRealTimeProcData_d
: RAS Real-time Procedure Data Characteristic UUID

gBleSig_RasOnDemandProcData_d
: RAS On-demand Procedure Data Characteristic UUID

gBleSig_RasControlPoint_d
: RAS Control Point Characteristic UUID

gBleSig_RasProcDataReady_d
: RAS Procedure Data Ready Characteristic UUID

gBleSig_RasprocDataOverwritten_d
: RAS Procedure Data Overwritten Characteristic UUID

BleSig_IsGroupingAttributeUuid16(uuid16)
: Macro that returns whether or not an input 16-bit UUID is a grouping type.

BleSig_IsServiceDeclarationUuid16(uuid16)
: Macro that returns whether or not an input 16-bit UUID is a Service declaration.

Uuid16(uuid)
: Macro that declares a 16 bit UUID in a *bleUuid_t* union.

Uuid32(uuid)
: Macro that declares a 32 bit UUID in a *bleUuid_t* union.

UuidArray(value)

PACKED_STRUCT
: Type qualifier - does not affect local variables of integral type

___noreturn
: Type qualifier - does not affect local variables of integral type

  Type qualifier - does not affect local variables of integral type

  Storage class modifier - alignment of a variable. It does not affect the type of the function

  Marks a function that never returns.

Utils_ExtractTwoByteValue(buf)
: Returns a uint16_t from a buffer, little-endian

Utils_ExtractThreeByteValue(buf)
: Returns a 3-byte value from a buffer, little-endian

Utils_ExtractFourByteValue(buf)
: Returns a uint32_t from a buffer, little-endian

Utils_ExtractEightByteValue(buf)
: Returns a uint64_t from a buffer, little-endian

Utils_BeExtractTwoByteValue(buf)
: Returns a uint16_t from a buffer, big-endian

Utils_BeExtractThreeByteValue(buf)
: Returns a 3-byte value from a buffer, big-endian

Utils_BeExtractFourByteValue(buf)
: Returns a uint32_t from a buffer, big-endian

Utils_PackTwoByteValue(value, buf)
: Writes a uint16_t into a buffer, little-endian

Utils_PackThreeByteValue(value, buf)
: Writes a 3-byte value into a buffer, little-endian

Utils_PackFourByteValue(value, buf)
: Writes a uint32_t into a buffer, little-endian

Utils_PackEightByteValue(value, buf)
: Writes a uint64_t into a buffer, little-endian

Utils_BePackTwoByteValue(value, buf)
: Writes a uint16_t into a buffer, big-endian

Utils_BePackThreeByteValue(value, buf)
: Writes a 3-byte value into a buffer, big-endian

Utils_BePackFourByteValue(value, buf)
: Writes a uint32_t into a buffer, big-endian

Utils_Copy8(ptr, val8)
: Writes a uint8_t into a buffer, little-endian, and increments the pointer.

Utils_Copy16(ptr, val16)
: Writes a uint16_t into a buffer, little-endian, and increments the pointer.

Utils_Copy32(ptr, val32)
: Writes a uint32_t into a buffer, little-endian, and increments the pointer.

Utils_Copy64(ptr, val64)
: Writes a uint64_t into a buffer, little-endian, and increments the pointer.

Utils_RevertByteArray(array, size)
: Reverts the order of bytes in an array - useful for changing the endianness

struct bleIdentityAddress_t
: *#include <ble_general.h>* Bluetooth Identity Address - array of 6 bytes.

Public Members

bleAddressType_t idAddressType
: Public or Random (static).

bleDeviceAddress_t idAddress
: 6-byte address.

union bleUuid_t
: *#include <ble_general.h>* Union for a Bluetooth UUID; selected according to an accompanying bleUuidType_t

Public Members

uint16_t uuid16
: For gBleUuidType16_c.

uint32_t uuid32
: For gBleUuidType32_c.

uint8_t uuid128[16]
: For gBleUuidType128_c.

struct bleAdvertisingChannelMap_t
: *#include <ble_general.h>*

Public Members

uint8_t enableChannel37
: Bit for channel 37.

uint8_t enableChannel38
: Bit for channel 38.

uint8_t enableChannel39
: Bit for channel 39.

uint8_t reserved
: Reserved for future use.

struct gapLeScOobData_t
: *#include <ble_general.h>*

Public Members

uint8_t randomValue[(16U)]

LE SC OOB r (Random value)

uint8_t confirmValue[(16U)]

LE SC OOB Cr (Random Confirm value)

struct gapInternalError_t

#include <ble_general.h> Internal Error Event Data

Public Members

bleResult_t errorCode

Host Stack error code.

gapInternalErrorSource_t errorSource

The command that generated the error; useful when it is not obvious from the error code.

uint16_t hciCommandOpcode

Only for errorSource = gHciCommandStatus_c; the HCI Command that received an error status.

struct gapControllerTestEvent_t

#include <ble_general.h> Controller Test Event

struct gapPhyEvent_t

#include <ble_general.h> Phy Event

struct bleNotificationEvent_t

#include <ble_general.h> Controller Enhanced Notification Event

Public Members

bleNotificationEventType_t eventType

Enhanced notification event type

deviceId_t deviceId

Device id of the peer, valid for connection events

int8_t rssi

RSSI, valid for Rx event types

uint8_t channel

Channel, valid for conn event over or Rx/Tx events

uint16_t ce_counter

Connection event counter, valid for conn event over or Conn Rx event

bleResult_t status

Status of the request to select which events to be enabled/disabled

uint32_t timestamp

Timestamp in microseconds, valid for Conn Rx event and Conn Created event

uint8_t adv_handle

Advertising Handle, valid for advertising events, if multiple ADV sets supported

bleDeviceAddress_t scanned_addr

Scanned address, valid for gNotifScanAdvPktRx_c event, all-zeroes otherwise

struct gapInitComplete_t

#include <ble_general.h> gInitializationComplete_c event data

struct bleBondCreatedEvent_tag

#include <ble_general.h> Bond Created Event

Public Members

uint8_t nvmIndex

NVM index for the new created bond

bleAddressType_t addressType

Public or Random (static) address of the bond

bleDeviceAddress_t address

Address of the bond

struct gapAddrReadyEvent_t_tag

#include <ble_general.h> Address Ready Event

Public Members

bleDeviceAddress_t aAddress

Generated device address

uint8_t advHandle

Advertising set handle if the generated device address will be used on an extended set. Reserved value 0xFF for other purposes: legacy advertising or scanning and initiating address.

struct bleSupportedSwitchingSamplingRates_t

#include <ble_general.h>

Public Members

uint8_t switchingSupportedAodTransmission
Bit to mark that 1 us switching is supported for AoD transmission.

uint8_t samplingSupportedAodReception
Bit to mark that 1 us sampling is supported for AoD reception.

uint8_t switchingSamplingSupportedAoaReception
Bit to mark that 1 us switching and sampling is supported for AoA reception.

uint8_t reserved
Reserved for future use.

struct bleAntennaInformation_tag
#include <ble_general.h> Antenna Information Read Event

struct periodicAdvSyncTransferEvent_tag
#include <ble_general.h>

struct periodicAdvSetInfoTransferEvent_tag
#include <ble_general.h>

struct periodicAdvSetSyncTransferParamsEvent_tag
#include <ble_general.h>

struct gapSyncTransferReceivedEventData_tag
#include <ble_general.h>

Public Members

deviceId_t deviceId
Id of the connected device from which we received periodic advertising sync transfer

uint16_t serviceData
A value provided by the peer device

uint16_t syncHandle
Sync Handle identifying the periodic advertising train

uint8_t advSID
Value of the Advertising SID used to advertise the periodic advertising

bleAddressType_t advAddressType
Device's advertising address type.

bleDeviceAddress_t advAddress
Device's advertising address.

gapLePhyMode_t advPhy
PHY used for advertising

uint16_t periodicAdvInt
Periodic advertising interval

bleCentralClockAccuracy_t advClockAccuracy
Advertiser clock accuracy

uint8_t numSubevents
Only relevant for v2 of the event, otherwise value is 0

uint8_t subeventInterval
Only relevant for v2 of the event, otherwise value is 0

uint8_t responseSlotDelay
Only relevant for v2 of the event, otherwise value is 0

uint8_t responseSlotSpacing
Only relevant for v2 of the event, otherwise value is 0

struct getConnParams_tag
#include <ble_general.h>

Public Members

uint16_t connectionHandle
Connection identifier

uint32_t ulTxAccCode
Access address

uint8_t aCrcInitVal[3U]
CRC init

uint16_t uiConnInterval
Connection interval (unit 1.25ms)

uint16_t uiSuperTO
Supervision timeout (unit 10ms)

uint16_t uiConnLatency
Latency (unit connection interval)

uint8_t aChMapBm[5U]
Channel map (FF FF FF FF 1F if all channels are used)

uint8_t ucChannelSelection
: Hop algorithm (0/1 for hop algorithm #1 or #2)

uint8_t ucHop
: Hop increment

uint8_t ucUnMapChIdx
: Unmapped channel index (used only for hop algorithm #1)

uint8_t ucCentralSCA
: Sleep clock accuracy (0 to 7)

uint8_t ucRole
: Role (0 for central and 1 for peripheral)

uint8_t aucRemoteMasRxPHY
: TX/RX PHY

uint8_t seqNum
: Sequence number; b1 and b0: the latest received SN and NESN; b5 and b4: the latest transmitted SN and NESN; other fields are reserved.

uint16_t uiConnEvent
: Current connection event counter

uint32_t ulAnchorClk
: Slot of the anchor point timing of the connection event

uint16_t uiAnchorDelay
: Slot offset of the anchor point timing of the connection event

uint32_t ulRxInstant
: Last successful access address reception instant (unit 625us)

struct handoverGetTime_tag
: *#include <ble_general.h>*

Public Members

bleResult_t status
: Command status

uint32_t slot
: LL timing slot counter (unit 625us)

uint16_t us_offset
: LL timing slot offset (0 to 624, unit us)

struct handoverAnchorSearchStart_tag

#include <ble_general.h>

Public Members

bleResult_t status

Command status

uint16_t connectionHandle

Connection identifier

struct handoverAnchorSearchStop_tag

#include <ble_general.h>

Public Members

bleResult_t status

Command status

uint16_t connectionHandle

Connection identifier

struct handoverConnect_tag

#include <ble_general.h>

Public Members

bleResult_t status

Command status

uint16_t connectionHandle

Connection identifier

struct handoverGetData_tag

#include <ble_general.h>

Public Members

bleResult_t status

Command status

uint32_t *pData

Connection handover data

struct handoverSetData_tag

#include <ble_general.h>

Public Members

bleResult_t status
Command status

uint32_t *pData
Connection handover data

struct handoverGetCsLlContext_tag
#include <ble_general.h>

Public Members

bleResult_t status
Command status

uint16_t responseMask
LL context bitmap indicating the Channel Sounding context

uint8_t llContextLength
Context data length

uint8_t llContext[(224U)]
LL Context

struct handoverAnchorMonitorEvent_tag
#include <ble_general.h>

Public Members

uint16_t connectionHandle
Connection identifier

uint16_t connEvent
Current connection event counter

int8_t rssiRemote
RSSI of the packet from the remote device (+127 if not available)

uint8_t lqiRemote
LQI (Link Quality Indicator) of the packet from the remote device

uint8_t statusRemote
Status of the packet from the remote device; b0: NESN; b1: SN; b2: CRC status valid (1) or invalid (0); b3: RSSI status valid (1) or invalid (0)

int8_t rssiActive
: RSSI of the packet from the active device (+127 if not available)

uint8_t lqiActive
: LQI (Link Quality Indicator) of the packet from the active device

uint8_t statusActive
: Status of the packet from the active device; b0: NESN; b1: SN; b2: CRC status valid (1) or invalid (0); b3: RSSI status valid (1) or invalid (0)

uint32_t anchorClock625Us
: Slot of the anchor point timing of the connection event

uint16_t anchorDelay
: Slot offset of the anchor point timing of the connection event

uint8_t chIdx
: BLE channel index

uint8_t ucNbReports
: Number of remaining reports including the current one; 0: continuous reporting; 1-255: remaining number of reports to receive including the current one

struct handoverAnchorMonitorPacketEvent_tag
: *#include <ble_general.h>*

Public Members

uint8_t packetCounter
: Packet counter, incremented for each event

uint16_t connectionHandle
: Connection identifier

uint8_t statusPacket
: Status of the packet

uint8_t phy
: PHY (0/1/2/3 for 1M/2M/LR S8/LR S2)

uint8_t chIdx
: BLE channel index

int8_t rssiPacket
: RSSI of the packet (+127 if not available)

uint8_t lqiPacket
: LQI (Link Quality Indicator) of the packet

uint16_t connEvent

Current connection event counter

uint32_t anchorClock625Us

Slot value of packet start time (in 625us unit)

uint16_t anchorDelay

Slot offset value of packet start time (in 1us unit)

uint8_t ucNbConnIntervals

Number of remaining connection intervals to monitor including the current one; 0: continuous reporting; 1-255: remaining number of reports to receive including the current one

uint8_t pduSize

PDU length

uint8_t *pPdu

Full or first part of the data PDU including: PDU header, payload if present, MIC if present, CRC

struct handoverAnchorMonitorPacketContinueEvent_tag

#include <ble_general.h>

Public Members

uint8_t packetCounter

Packet counter, incremented for each event

uint16_t connectionHandle

Connection identifier

uint8_t pduSize

PDU length

uint8_t *pPdu

Full or first part of the data PDU including: PDU header, payload if present, MIC if present, CRC

struct handoverConnectionUpdateProcedureEvent_tag

#include <ble_general.h>

Public Members

uint16_t connectionHandle

Connection identifier

uint8_t winSize

Used to indicate the transmitWindowSize value as: transmitWindowSize = winSize * 1.25 ms

uint16_t winOffset

Used to indicate the transmitWindowOffset value as: transmitWindowOffset = winOffset * 1.25 ms

uint16_t interval

Used to indicate the connInterval value, as: connInterval = interval * 1.25 ms

uint16_t latency

Used to indicate the connPeripheralLatency value as: connPeripheralLatency = latency

uint16_t timeout

Used to indicate the connSupervisionTimeout value as: connSupervisionTimeout = timeout * 10 ms

uint16_t instant

Connection event counter value indicating when the new connection parameters are applied

uint16_t currentEventCounter

Current connection event counter

struct handoverTimeSyncEvent_tag

#include <ble_general.h>

Public Members

uint32_t txClkSlot

Transmitter packet start time in slot (625 us)

uint16_t txUs

Transmitter packet start time offset inside the slot (0 to 624 us)

uint32_t rxClkSlot

Receiver packet start time in slot (625 us)

uint16_t rxUs

Receiver packet start time offset inside the slot (0 to 624 us)

uint8_t rssi

RSSI

struct handoverConnParamUpdateEvent_tag

#include <ble_general.h>

Public Members

uint8_t status

Status indicating the event trigger source: bit 0: remote SN^NESN toggled; bit 1: local SN^NESN toggled; bit 2: RFU; bit 3: phy update procedure; bit 4: channel map update procedure

uint16_t connectionHandle

Connection identifier

uint32_t ulTxAccCode

Access address

uint8_t aCrcInitVal[3U]

CRC init

uint16_t uiConnInterval

Connection interval (unit 1.25ms)

uint16_t uiSuperTO

Supervision timeout (unit 10ms)

uint16_t uiConnLatency

Latency (unit connection interval)

uint8_t aChMapBm[5U]

Channel map (FF FF FF FF 1F if all channels are used)

uint8_t ucChannelSelection

Hop algorithm (0/1 for hop algorithm #1 or #2)

uint8_t ucHop

Hop increment

uint8_t ucUnMapChIdx

Unmapped channel index (used only for hop algorithm #1)

uint8_t ucCentralSCA

Sleep clock accuracy (0 to 7)

uint8_t ucRole

Role (0 for central and 1 for peripheral)

uint8_t aucRemoteMasRxPHY

TX/RX PHY

uint8_t seqNum

Sequence number; b1 and b0: the latest received SN and NESN; b5 and b4: the latest transmitted SN and NESN; other fields are reserved.

uint16_t uiConnEvent

Current connection event counter

uint32_t ulAnchorClk

Slot of the anchor point timing of the connection event

uint16_t uiAnchorDelay

Slot offset of the anchor point timing of the connection event

uint32_t ulRxInstant

Last successful access address reception instant (unit 625us)

struct handoverSuspendTransmitCompleteEvent_tag

#include <ble_general.h>

Public Members

uint16_t connectionHandle

Connection identifier

uint8_t noOfPendingAclPackets

Number of pending ACL packets (including the packet being transmitted partially or fully but not fully acked)

uint16_t sizeOfPendingAclPackets

Pending ACL packet data size including all the data in the oldest packet:

- data transmitted but not acked in the oldest ACL packet
- data transmitted and acked in the oldest ACL packet

uint16_t sizeOfDataTxInOldestPacket

Size of data transmitted and acked in the oldest ACL packet

uint8_t sizeOfDataNAckInOldestPacket

Size of data transmitted but not acked in the oldest ACL packet

struct handoverResumeTransmitCompleteEvent_tag

#include <ble_general.h>

Public Members

uint16_t connectionHandle

Connection identifier

struct handoverUpdateConnParams_tag

#include <ble_general.h>

Public Members

bleResult_t status
Command status

uint16_t connectionHandle
Connection identifier

struct handoverApplyConnectionUpdateProcedure_tag
#include <ble_general.h>

Public Members

uint16_t connectionHandle
Connection identifier

struct handoverAnchorNotificationStateChanged_tag
#include <ble_general.h>

Public Members

uint16_t connectionHandle
Connection identifier

struct handoverLlPendingDataIndication_tag
#include <ble_general.h>

Public Members

uint16_t dataSize
Pending HCI ACL data packet size

uint8_t *pData
Pointer to message containing the HCI ACL data packet. Should be free by the application using MSG_Free()

struct gapLEGenerateDhKeyCompleteEvent_t
#include <ble_general.h>

struct gapRemoteVersionInfoRead_tag
#include <ble_general.h>

struct gapLlSkdReport_tag
#include <ble_general.h>

Public Members

deviceId_t deviceId
Peer device identifier

uint8_t aSKD[(16U)]
LL SKD

struct vendorUnitaryTestEvent_tag
#include <ble_general.h>

struct gapGenericEvent_t
#include <ble_general.h> Generic Event Structure = type + data

Public Members

gapGenericEventType_t eventType
Event type.

union *gapGenericEvent_t* eventData
Event data, selected according to event type.

struct bleBondIdentityHeaderBlob_t
#include <ble_general.h>

struct bleBondDataDynamicBlob_t
#include <ble_general.h>

struct bleBondDataStaticBlob_t
#include <ble_general.h>

struct bleBondDataLegacyBlob_t
#include <ble_general.h>

struct bleBondDataDeviceInfoBlob_t
#include <ble_general.h>

struct bleBondDataDescriptorBlob_t
#include <ble_general.h>

struct bleLocalKeysBlob_t
#include <ble_general.h>

struct bleBondDataBlob_t
#include <ble_general.h>

struct bleBondDataRam_t
#include <ble_general.h>

struct bleCteAllowedTypesMap_t

#include <ble_general.h>

Public Members

uint8_t allowAoA

Bit to allow AoA CTE Response.

uint8_t allowAoD1us

Bit to allow AoD CTE Response with 1 microsecond slots.

uint8_t allowAoD2us

Bit to allow AoD CTE Response with 2 microsecond slots.

uint8_t reserved

Reserved for future use.

struct bleSyncCteType_tag

#include <ble_general.h>

Public Members

uint8_t doNotSyncWithAoA

Bit for CTE type AoA.

uint8_t doNotSyncWithAoD1us

Bit for CTE type AoD 1us.

uint8_t doNotSyncWithAoD2us

Bit for CTE type AoD 2us.

uint8_t doNotSyncWithType3

Bit for CTE type 3 (reserved).

uint8_t doNotSyncWithoutCte

Bit for no CTE type.

uint8_t reserved

Reserved for future use.

struct bleTxPowerLevelFlags_t

#include <ble_general.h>

Public Members

uint8_t minimum

Tx Power Level is at minimum level.

uint8_t maximum

Tx Power Level is at maximum level.

uint8_t reserved

Reserved for future use.

union eventData

Public Members

gapInternalError_t internalError

Data for the gInternalError_c event. The error that has occurred and the command that triggered it.

uint8_t filterAcceptListSize

Data for the gFilterAcceptListSizeRead_c event. The size of the Filter Accept List.

bleDeviceAddress_t aAddress

Data for the gPublicAddressRead_c event. Contains the requested device address.

gapAddrReadyEvent_t addrReady

Data for the gRandomAddressReady_c event. Contains the generated device address and advertising handle if applicable (0xFF otherwise).

uint8_t advHandle

Data for the gRandomAddressSet_c event. Contains the handle of the configured advertising set or 0xFF for legacy advertising.

bleResult_t setupFailError

Data for the gAdvertisingSetupFailed_c event. The error that occurred during the advertising setup.

int8_t advTxPowerLevel_dBm

Data for the gExtAdvertisingParametersSetupComplete_c and gAdvTxPowerLevelRead_c events. Value in dBm.

bool_t verified

Data for the gPrivateResolvableAddressVerified_c event. TRUE if the PRA was resolved with the given IRK.

gapLeScOobData_t localOobData

Data for the gLeScLocalOobData_c event. Contains local OOB data for LESC Pairing.

bool_t newHostPrivacyState

Data for the gHostPrivacyStateChanged_c event. TRUE if enabled, FALSE if disabled.

bool_t newControllerPrivacyState

Data for the gControllerPrivacyStateChanged_c event. TRUE if enabled, FALSE if disabled.

gapControllerTestEvent_t testEvent

Data for the gControllerTestEvent_c event. Contains test event type and received packets.

bleResult_t txPowerLevelSetStatus

Data for the gTxPowerLevelSetComplete_c event. Status of the set request.

gapPhyEvent_t phyEvent

Data for the gLePhyEvent_c event. Contains Tx and Rx Phy for a connection.

deviceId_t deviceId

Data for the gTxEntryAvailable_c event.

gapInitComplete_t initCompleteData

Data for the gInitializationComplete_c event. Contains the supported features, number of advertising sets and the size of the periodic advertiser list

bleNotificationEvent_t notifEvent

Data for the gControllerNotificationEvent_c event. Contains status and adv/scan/conn event data.

bleBondCreatedEvent_t bondCreatedEvent

Data for the gBondCreatedEvent_c event. Contains the NVM index and the address of the bond.

bleDeviceAddress_t aControllerLocalRPA

Data for the gControllerLocalRPARead_c event. Contains the requested device address.

getConnParams_t getConnParams

Data for the gGetConnParamsComplete_c event

uint16_t syncHandle

Data for the gConnectionlessIqSamplingStateChanged_c event. Contains the sync handle for the advertising train.

bleAntennaInformation_t antennaInformation

Data for the gAntennaInformationRead_c. Contains antenna information.

bleResult_t perAdvSyncTransferEnable

Data for the gPeriodicAdvRecvEnableComplete_c event

periodicAdvSyncTransferEvent_t perAdvSyncTransfer

Data for the gPeriodicAdvSyncTransferComplete_c event

periodicAdvSetInfoTransferEvent_t perAdvSetInfoTransfer

Data for the gPeriodicAdvSetInfoTransferComplete_c event

periodicAdvSetSyncTransferParamsEvent_t perAdvSetSyncTransferParams

Data for the gSetPeriodicAdvSyncTransferParamsComplete_c event

bleResult_t perAdvSetDefaultPerAdvSyncTransferParams

Data for the gSetDefaultPeriodicAdvSyncTransferParamsComplete_c event

gapSyncTransferReceivedEventData_t perAdvSyncTransferReceived

Data for the gPeriodicAdvSyncTransferReceived_c event

gapLEGenerateDhKeyCompleteEvent_t leGenerateDhKeyCompleteEvent

Data for gConnEvtLeGenerateDhKeyComplete_c: new key value

uint16_t pawrSyncHandle

Bluetooth configuration

gcBleDeviceAddressSize_c
: Size of a BLE Device Address

gBleBondDataDynamicSize_c
: Size of bond data structures for a bonded device

gBleBondDataStaticSize_c

gBleBondDataLegacySize_c

gBleBondDataDeviceInfoSize_c

gBleBondDataDescriptorSize_c

gcSecureModeSavedLocalKeysNo_c

gcGapMaximumSavedCccds_c
: Maximum number of CCCDs

gcGapMaxAuthorizationHandles_c
: Maximum number of attributes that require authorization

gBleBondDataSize_c
: Bonding Data Size

gcBleLongUuidSize_c
: Size of long UUIDs

gcSmpMaxLtkSize_c
: Maximum Long Term Key size in bytes

gcSmpMaxBlobSize_c
: Maximum Long Term Key blob size in bytes

gcSmpIrkSize_c
: Identity Resolving Key size in bytes

gcSmpMaxIrkBlobSize_c
: Maximum Identity Resolving Key blob size in bytes

gcSmpCsrkSize_c
: Connection Signature Resolving Key size in bytes

gcSmpMaxRandSize_c
: Maximum Rand size in bytes

gcSmpOobSize_c
: SMP OOB size in bytes

gSmpLeScRandomValueSize_c

SMP LE Secure Connections Pairing Random size in bytes

gSmpLeScRandomConfirmValueSize_c

SMP LE Secure Connections Pairing Confirm size in bytes

gcGapMaxDeviceNameSize_c

Maximum device name size

gcGapMaxAdvertisingDataLength_c

Maximum size of advertising and scan response data

gAttDefaultMtu_c

Default value of the ATT_MTU

gAttMaxMtu_c

Maximum possible value of the ATT_MTU for this device. This is used during the MTU Exchange.

gEattMaxMtu_c

Maximum possible value of the ATT_MTU for enhanced ATT bearers on this device.

gAttMaxValueLength_c

The maximum length of an attribute value shall be 512 octets.

gEattMinMtu_c

Minimum MTU size for enhanced ATT channels is 64.

gHciTransportUartChannel_c

Channel the number of the UART hardware module (For example, if UART1 is used, this value should be 1).

gcReservedFlashSizeForCustomInformation_c

Number of bytes reserved for storing application-specific information about a device

gcBleChannelMapSize_c

Size of a channel map in a connection

gBleMinTxOctets_c

gBleMinTxTime_c

gBleMaxTxOctets_c

gBleMaxTxTime_c

gBleMaxTxTimeCodedPhy_c

gBleCteMinTxOctets_c

gBleCteMinTxTime_c

gBleCteMaxTxOctets_c

gBleCteMaxTxTime_c

gBleExtAdvMaxSetId_c
: Maximum value of the advertising SID.

gBlePeriodicAdvMaxSyncHandle_c
: Maximum value of the periodic advertising handle.

gBleExtAdvLegacySetId_c
: SID of the legacy advertising set.

gBleExtAdvLegacySetHandle_c
: Handle of the legacy advertising set.

gBleExtAdvDefaultSetId_c
: Default SID for extended advertising.

gBleExtAdvDefaultSetHandle_c
: Default handle for extended advertising.

gBleAdvTxPowerNoPreference_c
: Host has no preference for Tx Power

gBleExtAdvNoDuration_c
: No advertising duration. Advertising to continue until the Host disables it.

gBleHighDutyDirectedAdvDuration
: Default advertising duration in high duty directed advertising 1.28s = 1280ms/10ms(unit) = 128

gBleExtAdvNoMaxEvents_c
: No maximum number of advertising events.

gBlePeriodicAdvDefaultHandle_c
: Periodic advertising default handle.

gBlePeriodicAdvSyncTimeoutMin_c
: Minimum value for the sync_timeout parameter

gBlePeriodicAdvSyncTimeoutMax_c
: Maximum value for the sync_timeout parameter

gBlePeriodicAdvSkipMax_c
: Maximum value for the skip parameter

gBleMaxADStructureLength_c
: Maximum length of an AD structure

gBleMaxExtAdvDataLength_c
: Maximum length of Extended Advertising Data

gBleExtAdvMaxAuxOffsetUsec_c
: Maximum value in us of AUX Offset(13 bits) in AuxPtr in 300us units, i.e. ((1 « 13) - 1) * 300

gBleP256KeyLength_c
: Length of P-256 key in octets

gcDecisionDataKeySize_c
: decision data key size in bytes

gcDecisionInstructionsParamSize_c
: decision instructions parameter size in bytes

gcDecisionInstructionsArbitraryDataMaskSize_c
: decision instructions arbitrary data mask size in bytes

gcDecisionInstructionsArbitraryDataTargetSize_c
: decision instructions arbitrary data target size in bytes

gcDecisionDataPrandSize_c
: decision data random part size in bytes

gcDecisionDataMaxSize_c
: decision data maximum size in bytes

gcDecisionDataResolvableTagSize_c
: decision data maximum size in bytes

gcMaxNumTestsInDecisionInstruction_c
: The maximum number of tests in the Gap_SetDecisionInstructions ((max param length) - sizeof(numTests))/((sizeof(TestFlag) + sizeof(TestField) + sizeof(TestParameters)) = (255-1)/(1 + 1 + 16)

gcEadRandomizerSize_c
: Size of the Encrypted Advertising Data randomizer in bytes

gcEadMicSize_c
: Size of the Encrypted Advertising Data MIC in bytes

gcEadIvSize_c
: Size of the Encrypted Advertising Data Initialization Vector in bytes

gcEadKeySize_c

Size of the Encrypted Advertising Data Key in bytes

gcEadAadValue_c

Value of the Additional Authentication Data field for the CCM algorithm used by EAD

bleResult_t L2ca_RegisterLeCbCallbacks(*l2caLeCbDataCallback_t* pCallback, *l2caLeCbControlCallback_t* pCtrlCallback)

Registers callbacks for credit based data and control events on L2CAP.

Parameters

- pCallback – **[in]** Callback function for data plane messages.
- pCtrlCallback – **[in]** Callback function for control plane messages.

Return values

- gL2caSuccess_c – Successful callbacks installation.
- gL2caCallbackAlreadyInstalled_c – Callbacks already installed.

bleResult_t L2ca_RegisterLePsm(uint16_t lePsm, uint16_t lePsmMtu)

Registers the LE_PSM from the L2CAP.

Parameters

- lePsm – **[in]** Bluetooth SIG or Vendor LE_PSM.
- lePsmMtu – **[in]** MTU of the registered PSM.

Return values

- gL2caLePsmInsufficientResources_c – No free LE_PSM registration slot was found.
- gL2caLePsmInvalid_c – Invalid LE_PSM value.
- gL2caLePsmAlreadyRegistered_c – LE_PSM already registered.
- gL2caSuccess_c – Successful LE_PSM registration.

bleResult_t L2ca_DeregisterLePsm(uint16_t lePsm)

Unregisters the LE_PSM from the L2CAP.

Parameters

- lePsm – **[in]** Bluetooth SIG or Vendor LE_PSM.

Return values

- gL2caSuccess_c – Successful LE_PSM deregistration.
- gL2caLePsmNotRegistered_c – LE_PSM value not registered.
- gL2caInternalError_c – There are connected L2CAP channels for the LE_PSM

Pre

An LE_PSM must be registered a priori.

bleResult_t L2ca_ConnectLePsm(uint16_t lePsm, *deviceId_t* deviceId, uint16_t initialCredits)

Initiates a connection with a peer device for a registered LE_PSM.

Parameters

- lePsm – **[in]** Bluetooth SIG or Vendor LE_PSM.
- deviceId – **[in]** The DeviceID for which the command is intended.
- initialCredits – **[in]** Initial credits.

Return values

- gL2caSuccess_c – Successful application to host message sent.
- gBleOutOfMemory_c – Message allocation fail.
- gBleInvalidParameter_c – Invalid Device Id.

Pre

An LE_PSM must be registered a priori.

bleResult_t L2ca_DisconnectLeCbChannel(*deviceId_t* deviceId, uint16_t channelId)

Disconnects a peer device for a registered LE_PSM.

Remark

Once this command is issued, all incoming data in transit for this device shall be discarded and any new additional outgoing data shall be discarded.

Parameters

- deviceId – **[in]** The DeviceID for which the command is intended.
- channelId – **[in]** The L2CAP Channel Id assigned on the initiator.

Return values

- gL2caSuccess_c – Successful application to host message sent.
- gBleOutOfMemory_c – Message allocation fail.
- gBleInvalidParameter_c – Invalid Device Id.

Pre

A connection must have already been created.

bleResult_t L2ca_CancelConnection(uint16_t lePsm, *deviceId_t* deviceId,
l2caLeCbConnectionRequestResult_t refuseReason)

Terminates an L2CAP channel.

Remark

This interface can be used for a connection pending creation.

Parameters

- lePsm – **[in]** Bluetooth SIG or Vendor LE_PSM.
- deviceId – **[in]** The DeviceID for which the command is intended.
- refuseReason – **[in]** Reason to refuse the channel creation.

Return values

- gL2caSuccess_c – Successful application to host message sent.
- gBleOutOfMemory_c – Message allocation fail.
- gBleInvalidParameter_c – Invalid Device Id.

bleResult_t L2ca_SendLeCbData(*deviceId_t* deviceId, uint16_t channelId, const uint8_t *pPacket, uint16_t packetLength)

Sends a data packet through a Credit-Based Channel.

Parameters

- deviceId – **[in]** The DeviceID for which the command is intended.
- channelId – **[in]** The L2CAP Channel Id assigned on the initiator.
- pPacket – **[in]** Data buffer to be transmitted.
- packetLength – **[in]** Length of the data buffer.

Return values

- gL2caSuccess_c – Successful application to host message sent.
- gBleInvalidParameter_c – Invalid Device Id.
- gBleOverflow_c – Tx queue of the device is not empty.
- gBleOutOfMemory_c – Message or packet allocation fail.

Pre

An L2CAP Credit Based connection must be in place.

bleResult_t L2ca_SendLeCredit(*deviceId_t* deviceId, uint16_t channelId, uint16_t credits)

Sends credits to a device when capable of receiving additional LE-frames.

Parameters

- deviceId – **[in]** The DeviceID to which credits are given.
- channelId – **[in]** The L2CAP Channel Id assigned on the initiator.
- credits – **[in]** Number of credits to be given.

Return values

- gL2caSuccess_c – Successful application to host message sent.
- gBleOutOfMemory_c – Message allocation fail.
- gBleInvalidParameter_c – Invalid device id.

Pre

An L2CAP Credit Based connection must be in place.

bleResult_t L2ca_EnhancedConnectLePsm(uint16_t lePsm, *deviceId_t* deviceId, uint16_t mtu, uint16_t initialCredits, uint8_t noOfChannels, uint16_t *aCids)

Initiates a connection with a peer device for a registered LE_PSM. Enhanced mode: up to 5 channels can be opened.

Parameters

- lePsm – **[in]** Bluetooth SIG or Vendor LE_PSM.
- deviceId – **[in]** The DeviceID for which the command is intended.
- initialCredits – **[in]** Initial credits.
- noOfChannels – **[in]** Number of channels to request for opening. Max 5.

- aCids – **[in]** List of cids if an Enhanced Connection Request has been previously received. NULL if not.

Return values

- gL2caSuccess_c – Successful application to host message sent.
- gBleOutOfMemory_c – Message allocation fail.
- gBleInvalidParameter_c – Invalid device id or invalid noOfChannels.

Pre

A LE_PSM must be registered a priori.

bleResult_t L2ca_EnhancedChannelReconfigure(*deviceId_t* deviceId, uint16_t newMtu, uint16_t newMps, uint8_t noOfChannels, uint16_t *aCids)

Reconfigures up to 5 channels with new values for MTU and/or MPS.

Parameters

- deviceId – **[in]** The DeviceID for which the command is intended.
- newMtu – **[in]** New MTU value to be configured.
- newMps – **[in]** New MPS value to be configured.
- noOfChannels – **[in]** Number of channels to reconfigure. Max 5.
- *aCids – **[in]** The list of CIDs (endpoints on local device).

Return values

- gL2caSuccess_c – Successful application to host message sent.
- gBleOutOfMemory_c – Message allocation fail.
- gBleInvalidParameter_c – Invalid device id or invalid noOfChannels.

bleResult_t L2ca_EnhancedCancelConnection(uint16_t lePsm, *deviceId_t* deviceId, *l2caLeCbConnectionRequestResult_t* refuseReason, uint8_t noOfChannels, uint16_t *aCids)

Termination of pending L2CAP channels.

Remark

This interface can be used for an enhanced connection pending creation.

Parameters

- lePsm – **[in]** Bluetooth SIG or Vendor LE_PSM.
- deviceId – **[in]** The DeviceID for which the command is intended.
- refuseReason – **[in]** Reason to refuse the channel creation.
- noOfChannels – **[in]** Number of channels to disconnect. Max 5.
- *aCids – **[in]** The list of CIDs (endpoints on local device).

Return values

- gL2caSuccess_c – Successful application to host message sent.
- gBleOutOfMemory_c – Message allocation fail.
- gBleInvalidParameter_c – Invalid device id, invalid noOfChannels or invalid aCids pointer.

Wireless Framework

Wireless Connectivity Framework Connectivity Framework repository provides both connectivity platform enablement with hardware abstraction layer and a set of Services for NXP connectivity stacks : BLE, Zigbee, OpenThread, Matter.

The connectivity framework repository consists of:

- Common folder to common header files for minimal type definition to be used in the repo
- Platform folder used for platform enablement with Hardware abstraction:
  - platform/include: common API header files used by several platforms
  - platform/common: common code for several platforms
  - specifics platform folders , See below the supported platform list
  - platform/../configs folder: configuration files for framework repository and other middlewares (rpmsg, mbedTls, etc.._)
- Services folder
- Zephyr folder for zephyr modules integrated in mcux SDK
- clang formatting script and script folder to format appropriately the source files of the repo

Supported platforms The following devices/platforms are supported in platform folder for connectivity applications:

- kw45x, k32w1x, mcxw71x, under wireless_mcu, kw45_k32w1_mcxw71 folders.
- kw47x, mcxw72x families under wireless_mcu, kw47_mcxw72, kw47_mcxw72_nbu folders.
- rw61x
- RT1060 and RT1170 for Matter
- Other RT devices such as i.MX RT595s

Supported services The supported services are provided for connectivity stacks and their demo application, and are usually dependent on PLATFORM API implementation:

- DBG: Light Debug Module, currently a stubbed header file
- FSCI: Framework Serial Communication Interface between BLE host stack and upper layer located on an other core/device
- FunctionLib: wrapper to toolchain memory manipulation functions (memcpy, memcmp, etc) or use its own implementation for code size reduction

- HWParameters: Store Factory hardware parameters and Application parameters in Flash or IFR
- LowPower: wrapper of SDK power manager for connectivity applications
- ModuleInfo: Store and handle connectivity component versions
- NVM: NXP proprietary File System used for KW45, KW47 automotive devices and RT1060/RT1170 platform for Matter
- OtaSupport: Handle OTA binary writes into internal or external flash.
- SecLib and RNG: Crypto and Random Number generator functions. It supports several ports:
  - Software algorithms
  - Secure subsystem interface to an HW enclave
  - MbedTls 2.x interface
- Sensors: Provides service for Battery and temperature measurements
- SFC: Smart Frequency Calibration to be run from KW47/MCXW71 from NBU core. Matter related modules:
- OTW: Over The Wire module for External Transceiver firmware update from RT platforms
- FactoryDataProvider to be used for Matter

Supported Zephyr modules integration in mcux SDK Connectivity framework provides integration and port layers to the following Zephyr Modules located into zephyr/subsys:

- NVS: Zephyr File System used by Matter and Zigbee
- Settings: Over layer module that allows to store keys into NVS File System used by Matter Port layer and required libraries for these zephyr modules are located in port and lib folder in zephyr directory

Connectivity framework CHANGELOG

7.0.3 revB mcux SDK 25.09.00

Major Changes

- [wireless_mcu] Adjusted default value of BOARD_RADIO_DOMAIN_WAKE_UP_DELAY from 0x16 to 0x10 to address stability issues observed with the previous setting. This change enhances system reliability but will reduce low-power performance.

Minor Changes (bug fixes)

- [Common] Added MDK compatibility for the errno framework header.
- [mcxw23] Implemented missing PLATFORM_OtaClearBootInterface() API.
- [mcxw23] Refactored fwk_platform.c to separate BLE-specific logic into fwk_platform_ble.c.
- [OTA] Corrected definition of gEepromParams_WriteAlignment_c flag for mcxw23
- [OTA] Enabled calling OTA_GetImgState() prior to OTA_Initialize().
- [wireless_mcu] Fixed PLATFORM_IsExternalFlashSectorBlank() to check the entire sector instead of just one page.

- [mcxw23] Added support for OTA using external flash.
- [mcxw23] Introduced PLATFORM_GetRadioIdleDuration32K() to estimate time until next radio event.
- [OTA] Removed gUseInternalStorageLink_d linker flag definition when external OTA storage is used.
- [mcxw23] Extended CopyAndReboot() to support external flash OTA.
- [wireless_mcu] Resolved counter wrap issue in PLATFORM_GetDeltaTimeStamp().
- [kw43_mcxw70] Defined LPTMR frequency constants in fwk_platform_definitions.h.
- [kw47_mcxw72] Updated shared memory allocation for RPMsg adapter.
- [mcxw23] Implement PLATFORM_IsExternalFlashBusy() API.
- [kw45_mcxw71][kw47_mcxw72] Moved RAM bank definitions from the connectivity framework to device-specific definitions.

7.0.3 revA mcux SDK 25.09.00

Major Changes

- [wireless_nbu] Enhanced XTAL32M trimming handling: updates are applied when requested by the application core and the NBU enters low-power mode, ensuring no interference from ongoing radio activity. Introduced new APIs to lock (PLATFORM_LockXtal32MTrim()) and unlock XTAL32M (PLATFORM_UnlockXtal32MTrim()) trimming updates using a counter-based mechanism. Also added a reset API (PLATFORM_ResetContext()) for platform-specific variables (currently limited to the trimming lock).
- [wireless_mcu] Introduced a new API, PLATFORM_SetLdoCoreNormalDriveVoltage(), to enable support for NBU clock frequency at 64 MHz, as required by BLE channel sounding applications.
- [wireless_mcu][wireless_nbu] Increased delayLpoCycle default from 2 to 3 to address link layer instabilities in low-power NBU use cases. Adjusted BOARD_RADIO_DOMAIN_WAKE_UP_DELAY from 0x10 to 0x16 to balance power consumption and stability. NBU may malfunction if delayLpoCycle (or BOARD_LL_32MHz_WAKEUP_ADVANCE_HSLOT) is set to 2 while BOARD_RADIO_DOMAIN_WAKE_UP_DELAY is 0x16.

Minor Changes (bug fixes)

- [WorkQ] Increased stack size when RNG use mbedtls port and coverage is enabled.
- [FSCI] Resolved an issue where messages remained unprocessed in the queue by ensuring OSA_EventSet() is triggered when pending messages are detected.
- [OTA] Fixed a bug in in OTA_PullImageChunk() that prevented retrieval of data previously received via OTA_PushImageChunk() when still buffered in RAM during posted operations.
- [OTA] Various MISRA and coverity fixes.
- [mcxw23] Fixed an unused variable warning in PLATFORM_RegisterNbuTemperatureRequestEventCb() API.
- [SFC] Remove obsolete flag gNbuJtagCapability.
- [wireless_mcu] Introduced new API PLATFORM_GetRadioIdleDuration32K(). Deprecated PLATFORM_CheckNextBleConnectivityActivity() API.

- [mcxw23] Aligned platform-specific implementations with the corresponding prototypes defined in wireless_mcu.
- [DBG] Cleaned up fwk_fault_handler.c.

7.0.2 RFP mcux SDK 25.06.00

Major Changes

- [wireless_mcu][wireless_nbu] Introduced PLATFORM_Get32KTimeStamp() API, available on platforms that support it.
- [RNG] Switched to using a workqueue for scheduling seed generation tasks.
- [Sensors] Integrated workqueue to trigger temperature readings on periodic timer expirations.
- [wireless_nbu] Removed outdated configuration files from wireless_nbu/configs.
- [SecLib_RNG][PSA] Added a PSA-compliant implementation for SecLib_RNG. This is an experimental feature and should be used with caution.
- [wireless_mcu][wireless_nbu] Implemented PLATFORM_SendNBUXtal32MTrim() API to transmit XTAL32M trimming values to the NBU.

Minor Changes (bug fixes)

- [MWS] Migrated the Mobile Wireless Standard (MWS) service to the public repository. This service manages coexistence between connectivity protocols such as BLE, 802.15.4, and GenFSK.
- [HWParameter][NVM][SecLib_RNG][Sensors] Addressed various MISRA compliance issues across multiple modules.
- [Sensors] Applied a filtering mechanism to temperature data measured by the application core before forwarding it to the NBU, improving data reliability.
- [Common] Relocated the GetPowerOfTwoShift() function to a shared module for broader accessibility across components.
- [RNG] Resolved inconsistencies in RNG behavior when using the fsl_adapter_rng HAL by aligning it with other API implementations.
- [SecLib] Updated the AES CMAC block counter in AES_128_CMAC() and AES_128_CMAC_LsbFirstInput() to support data segments larger than 4KB.
- [SecLib] Utilized sss_sscp_key_object_free() with kSSS_keyObjFree_KeysStoreDefragment to avoid key allocation failures.
- [MCXW23] Removed redundant NVIC_SetPriority() call for the ctimer IRQ in the platform file, as it's already handled by the driver.
- [WorkQ] Increased workqueue stack size to accommodate RNG usage with mbedtls.
- [wireless_mcu][ot] Suppressed chip revision transmission when operating with nbu_15_4.
- [platform][mflash] Ensured proper address alignment for external flash reads in PLATFORM_ReadExternalFlash() when required by platform constraints.
- [RNG] Corrected reseed flag behavior in RNG_GetPseudoRandomData() after reaching gRngMaxRequests_d threshold.
- [platform][mflash] Fixed uninitialized variable issue in PLATFORM_ReadExternalFlash().

- [platform][wireless_nbu] Fixed an issue on KW47 where PLATFORM_InitFro192M incorrectly reads IFR1 from a hardcoded flash address (0x48000), leading to unstable FRO192M trimming. The function is now conditionally compiled for KW45 only.

7.0.2 revB mcux SDK 25.06.00

Major Changes

- [RNG][wireless_mcu][wireless_nbu] Rework RNG seeding on NBU request
- [wireless_mcu] [LowPower] Add gPlatformEnableFro6MCalLowpower_d macro to enable FRO6M frequency verification on exit of Low Power
  - add PLATFORM_StartFro6MCalibration() and PLATFORM_EndFro6MCalibration() new function for FRO6M calibration (6MHz or 2Mhz) on wake-up from low power mode.
  - Enabled by default in fwk_config.h
- [wireless_nbu][LowPower] Clear pending interrupt status of the systick before going in low-power - Reduce NBU active time
- [wireless_nbu] Fix impossibility to go to WFI in combo mode (15.4/BLE)
- [wireless_mcu] Implement XTAL32M temperature compensation mechanism. 2 new APIs:
  - PLATFORM_RegisterXtal32MTempCompLut(): register the temperature compensation table for XTAL32M.
  - PLATFORM_CalibrateXtal32M(): apply XTAL32M temperature compensation depending on current temperature.
- [Sensors][wireless_mcu] Add support for periodic temperature measurement. new API:
  - SENSORS_TriggerTemperatureMeasurementUnsafe(): to be called from Interrupt masked critical section, from ISR or when scheduler is stopped
- [SFC] Change default maximal ppm target of the SFC algorithm from 200 to 360ppm. Impact the SFC algorith of kw45 and mcxw71 platforms, 360ppm was already the default setting for kw47 and mcxw72 platforms

Minor Changes (bug fixes)

- [DBG] Fix FWK_DBG_PERF_DWT_CYCLE_CNT_STOP macro
- [wireless_nbu] Add gPlatformIsNbu_d compile Macro set to 1
- [wireless_nbu][ics] gFwkSrvHostChipRevision_c can be processed in the system workqueue
- [kw45_mcxw71][kw47_mcxw72]
  - Remove LTC dependency from platform in kconfig
  - gPlatformShutdownEccRamInLowPower moved from fwk_platform_definition.h to fwk_confg.h as this is a configuration flag.
- [wireless_mcu][sensors] Rework and remove unnecessary ADC APIs
- [wireless_nbu] Add PLATFORM_GetMCUUid() function from Chip UID
- [SecLib] Change AES_MMO_BlockUpdate() function from private to public for zigbee.

7.0.2 revA mcux SDK 25.06.00 **Supported platforms:**

- Same as 25.03.00 release

Major Changes

- [KW45/MCXW71] HW parameters placement now located in IFR section. Flash storage is not longer used:
  - Compilation: Macro gHwParamsProdDataPlacement_c changed from gHwParamsProdDataMainFlash2IfrMode_c to gHwParamsProdDataIfrMode_c
- [KW47] NBU: Add new fwk_platform_dcdc.[ch] files to allow DCDC stepping by using SPC high power mode. This requires new API in board_dcdc.c files. Please refer to new compilation MACROs gBoardDcdcRampTrim_c and gBoardDcdcEnableHighPowerModeOnNbu_d in board_platform.h files located in kw47evk, kw47loc, frdmmcxw72 board folders.
- [KW45/MCXW71/KW47/MCXW72] Trigger an interrupt each time App core calls PLATFORM_RemoteActiveReq() to access NBU power domain in order to restart NBU core for domain low power process

Minor Changes (bug fixes)

Services

- [SecLib_RNG]
  - Rename mSecLibMutexId mutex to mSecLibSssMutexId in SecLib_sss.c
  - Remove MEM_TRACKING flag from RNG.c
  - Implement port to fsl_adapter_rng.h API using gRngUseRngAdapter_c compil Macro from RNG.c
  - Add support for BLE debug Keys in SecLi and SecLin_sss.c with gSecLibUseBleDebugKeys_d - for Debug only
- [FSCI] Add queue mechanism to prevent corruption of FSCI global variableAllow the application to override the trig sample number parameter when gFsciOverRpmsg_c is set to 1
- [DBG][btsnoop] Add a mechanism to dump raw HCI data via UART using SBTSNOOP_MODE_RAW
- [OTA]
  - OtaInternalFlash.c: Take into account chunks smaller than a flash phrase worth
  - fwk_platform_ot.c: dependencies and include files to gpio, port, pin_mux removed

Platform specific

- [kw45_mcxw71][kw47_mcxw72]
  - fwk_platform_reset.h : add compil Macro gUseResetByLvdForce_c and gUseResetByDeepPowerDown_c to avoid compile the code if not supported on some platforms
  - New compile Flag gPlatformHasNbu_d
  - Rework FRO32K notification service for MISRA fix

7.0.1 RFP mcux SDK 25.03.00 Supported platforms:

- KW45x, KW47x, MCXW71, MCXW72, K32W1x
- RW61x
- RT595, RT1060, RT1170
- MCXW23

Minor Changes (bug fixes)

- [General] Various MISRA/Coverity fixes in framework: NVM, RNG, LowPower, SecLib and platform files

Services

- [SecLib_RNG] fix return status from RNG_GetTrueRandomNumber() function: return correctly gRngSuccess_d when RNG_entropy_func() function is successful
- [SFC] Allow the application to override the trig sample number parameter
- [Settings] Re-define the framework settings API name to avoid double definition when gSettingsRedefineApiName_c flag is defined

Platform specific

- [wireless_mcu] fwk_platform_sensors update :
  - Enable temperature measurement over ADC ISR
  - Enable temperature handling requested by NBU
- [wireless_mcu] fwk_platform_lcl coex config update for KW45
- [kw47_mcxw72] Change the default ppm_target of SFC algorithm from 200 to 360ppm

7.0.1 revB mcux SDK 25.03.00 Supported platforms:

- KW45x, KW47x, MCXW71, MCXW72, K32W1x
- RW61x
- RT595, RT1060, RT1170
- MCXW23

Minor Changes (bug fixes)

General

- [General] Various MISRA/Coverity fixes in framework: NVM, RNG, LowPower, FunctionLib and platform files

Services

- [SecLib_RNG] AES-CBC evolution:
  - added AES_CBC_Decrypt() API for sw, SSS and mbedtls variants.
  - Made AES-CBC SW implementation reentrant avoiding use of static storage of AES block.
  - fixed SSS version to update Initialization Vector within SecLib, simplifying caller's implementation.
  - modified AES_128_CBC_Encrypt_And_Pad() so as to avoid the constraint mandating that 16 byte headroom be available at end of input buffer.
- [SecLib_RNG] RNG modifications:
  - RNG_GetPseudoRandomData() could return 0 in some error cases where caller expected a negative status.

    - Explicited RNG error codes
    - Added argument checks for all APIs and return gRngBadArguments_d (-2) when wrong
    - added checks of RNG initalization and return gRngNotInitialized_d (-3) when not done
    - fixed correcteness of RNG_GetPrngFunc() and RNG_GetPrngContext() relative to API description.
    - Added RNG_DeInit() function mostly for test and coverage purposes.
    - Improved RNG description in README.md
    - Unified the APIs behaviour between mbedtls and non mbedtls variants.
  - RNG/mbedtls : Prevent RNG_Init() from corrupting RNG entropy context if called more than once.
  - RNG/mbedtls: fixed RNG_GetTrueRandomNumber() to return a proper mbedtls_entropy_func() result.
  - Use defragmetation option when freeing key object in SecLib_sss to avoid leak in S200 memory
  - Add new API ECP256_IsKeyValid() to check whether a public key is valid
- [OtaSupport] Update return status to OTA_Flash_Success when success at the end of InternalFlash_WriteData() and InternalFlash_FlushWriteBuffer() APIs
- [WorQ] Implementing a simple workqueue service to the framework
- [SFC] Keep using immediate measurement for some measurement before switching to configuration trig to confirm the calibration made
- [DBG] Adding modules to framework DBG :
  - sbtsnoop
  - SWO
- [Common] Fix HAL_CTZ and HAL_RBIT IAR versions
- [LowPower] Fix wrong tick error calculation in case of infinite timeout
- [Settings] Add new macro gSettingsRedefineApiName_c to avoid multiple definition of settings API when using connectivity framework repo

Platform specific

- [KW47/MCXW72] Change xtal cload default value from 4 to 8 in order to increase the precision of the link layer timebase in NBU
- [wireless_mcu] [wireless_nbu] Use new WorkQ service to process framework intercore messages
- [rw61x] Fix HCI message sending failure in some corner case by releasing controller wakes up after that the host has send its HCI message
- [MCXW23] Adding the initial support of MCXW23 into the framework

7.0.0 mcux SDK 24.12.00 Supported platforms:

- KW45x, KW47x, MCXW71, MCXW72, K32W1x
- RW61x
- RT595, RT1060, RT1170

Minor Changes (bug fixes)

Platform specific

- [RW61X]
  - Add MCUX_COMPONENT_middleware.wireless.framework.platform.rng to the platform to fix a warning at generation
  - Retrieve IEEE 64 bits address from OTP memory
- [KW45x, MCXW71x, KW47x, MCXW72x]
  - Ignore the secure bit from RAM addresses when comparing used ram bank in bank retention mechanism
  - Add gPlatformNbuDebugGpioDAccessEnabled_d Compile Macro (enabled by default). Can be used to disable the NBU debug capability using IOs in case Trustzone is enabled ("PLATFORM_InitNbu()' code executed from unsecure world).
  - Fix in NBU firmware when sending ICS messages gFwkSrvNbuApiRequest_c (from controller_api.h API functions)

Services

- [OTA]
  - Add choice name to OtaSupport flash selection in Kconfig
- [NVM]
  - Add gNvmErasePartitionWhenFlashing_c feature support to gcc toolchain
- [SecLib_RNG]
  - Misra fixes

7.0.0 revB mcux SDK 24.12.00 Supported platforms: KW45x, KW47x, MCXW71, MCXW72, K32W1x, RW61x, RT595, RT1060, RT1170

Major Changes (User Applications may be impacted)

- mcux github support with cmake/Kconfig from sdk3 user shall now use CmakeLists.txt and Kconfig files from root folder. Compilation should be done using west build command. In order to see the Framework Kconfig, use command >west build -t guiconfig
- Board files and linker scripts moved to examples repository

Bugfixes

- [platform lowpower]
  - Entering Deep down power mode will no longer call PLATFORM_EnterPowerDown(). This API is now called only when going to Power down mode

Platform specific

- [KW47/MCXW72]: Early access release only
  - Deep sleep power mode not fully tested. User can experiment deep sleep and deep down modes using low power reference design applications

  - XTAL32K-less support using FRO32K not tested
- [KW45/MCXW71/K32W148]
  - Deep sleep mode is supported. Power down mode is supported in low power reference design applications as experimental only
  - XTAL32K-less support using FRO32K is experimental - FRO32K notifications callback is debug only and should not be used for mass production firmware builds

Minor Changes (no impact on application)

- Overall folder restructuring for SDK3
  - [Platform]:
    * Rename platform_family from connected_mcu/nbu to wireless_mcu/nbu
    * platform family have now a dedicated fwk_config.h, rpmsg_config.h and SecLib_mbedtls_config.h
  - [Services]
    * Move all framework services in a common directory “services/”

7.0.0 revA: KW45/KW47/MCX W71/MCX W72/K32W148

Experimental Features only

- Power down on application power domain: Some tests have shown some failure. Power consumption higher than Deep Sleep. => This feature is not fully supported in this release
- XTAL32K less board with FRO32K support: Some additional stress tests are under progress.
- FRO32K notifications callback is for debug only and shall not be used for production. User shall not execute long processing (such as PRINTF) as it is executed in ISR context.

Main Changes

- Cmake/Kconfig support for SDK3.0
- [Sensors] API renaming:
  - $\mathrm{SENSORS_InitAdc()}$ renamed to $\mathrm{SENSORS_Init()}$
  - $\mathrm{SENSORS_DeinitAdc()}$ remamed to $\mathrm{SENSORS_Deinit()}$
- [HWparams]
  - Repair PROD_DATA sector in case of ECC error (implies loss of previous contents of sector)
- [NVM] Linker script modification for armgcc whenever gNvTableKeptInRam_d option is used:
  - placement of NVM_TABLE_RW in data initialized section, providing start and end address symbols. For details see NVM_Interface.h comments.
- [OtaSupport]
  - $\mathrm{OTA_Initialize()}$: now transitions the image state from RunCandidate to Permanent if not done by the application. OTA module shall always be initialized on a Permanent image, this change ensures it is the case.
  - $\mathrm{OTA_MakeHeadRoomForNextBlock()}$: now erases the OTA partition up to the image total size (rounded to the sector) if known.

Minor changes

- [Platform]
  - Updated macro values: -kw47: BOARD_32MHZ_XTAL_CDAC_VALUE from 12U to 16U, BOARD_32MHZ_XTAL_ISEL_VALUE from 7U to 11U, BOARD_32KHZ_XTAL_CLOAD_DEFAULT from 8U to 4U, BOARD_32KHZ_XTAL_COARSE_ADJ_DEFAULT from 1U to 3U
    * MCX W72 (low-power reference design applications only): BOARD_32MHZ_XTAL_CDAC_VALUE from 12U to 10U, BOARD_32MHZ_XTAL_ISEL_VALUE from 7U to 11U, BOARD_32KHZ_XTAL_CLOAD_DEFAULT from 8U to 4U, BOARD_32KHZ_XTAL_COARSE_ADJ_DEFAULT from 1U to 3U
  - New PLATFORM_RegisterNbuTemperatureRequestEventCb() API: register a function callback when NBU request new temperature measurement. API provides the interval request for the temperature measurement
  - Update PLATFORM_IsNbuStarted() API to return true only if the NBU firmware has been started.
- [platform lowpower]
  - Move RAM layout values in fwk_platform_definition.h and update RAM retention API for KW47/MCXW72

Bugfixes

- [OtaSupport]
  - OTA_MakeHeadRoomForNextBlock(): fixed a case where the function could try to erase outside the OTA partition range.

6.2.4: KW45/K32W1x/MCXW71/RX61x SDK 2.16.100 This release does not contain the changes from 6.2.3 release.

This release contains changes from 6.2.2 release.

Main Change

- armgcc support for Cmake sdk2 support and VS code integration

Minor changes

- [NBU]
  - Optimize some critical sections on nbu firmware
- [Platform]
  - Optimize PLATFORM_RemoteActiveReq() execution time.

6.2.3: KW47 EAR1.0 Initial Connectivity Framework enablement for KW47 EAR1.0 support.

New features

- OpenNBU feature : nbu_ble project is available for modification and building

Supported features

- Deep sleep mode

Unsuported features

- Power down mode
- FRO32K support (XTAL32K less boards)

Main changes

- [NBU]
  - LPTMR2 available and TimerManager initialization with Compile Macro: gPlatformUseLptmr_d
  - NBU can now have access to GPIOD
  - SW RNG and SW SecLib ported to NBU (Software implementation only)
- [RNG]
  - Obsoleted API removed : FWK_RNG_DEPRECATED_API
  - RNG can be built without SecLib for NBU, using gRngUseSecLib_d in fwk_config.h
  - Some API updates:
    - RNG_IsReseedneeded() renamed to RNG_IsReseedNeeded,
    - RNG_TriggerReseed() renamed to RNG_NotifyReseedNeeded(),
    - RNG_SetSeed() and RNG_SetExternalSeed() return status code.
  - Optimized Linear Congruential modulus computation to reduce cycle count.

Minor changes

- [NVM]
  - Optimize NvIsRecordErased() procedure for faster garbage collection
  - MISRA fix : Remove externs and weaks from NVM module - Make RNG and timer manager dependencies conditional
- [Platform]
  - Allow the debugger to wakeup the KW47/MCXW72 target

6.2.2: KW45/K32W1 MR6 SDK 2.16.000 Experimental Features only:

- Power down on application power domain : Some tests have shown some failure. Power consumption higher than Deep Sleep. => This feature is not fully supported in this release
- XTAL32K less board with FRO32K support : Some additional stress tests are under progress.
- FRO32K notifications callback is for debug only and shall not be used for production. User shall not execute long processing (such as PRINTF) as it is executed in ISR context.

Changes

- [Board] Support for freedom board FRDM-MCX W7X
- [HWparams]
  - Support for location of HWParameters and Application Factory Data IFR in IFR1
  - Default is still to use HWparams in Flash to keep backward compatibility
- [RNG]: API updates:
  - New APIS RNG_IsReseedneeded(), RNG_SetSeed() to provide See to PRNG on NBU/App core - See BluetoothLEHost_ProcessIdleTask() in app_conn.c
  - New APIs RNG_SetExternalSeed() : User can provide external seed. Typically used on NBU firmrware for App core to set a seed to RNG. RNG_TriggerReseed() : Not required on App core. Used on NBU only.
- [NVS] Wear statistics counters added - Fix nvs_file_stat() function
- [NVM] fix Nv_Shutdown() API
- [SecLib] New feature AES MMO supported for Zigbee

6.2.2: RW61x RFP4 SDK 2.16.000

- [Platform] Support Zigbee stack
- [OTA] Add support for RW61x OTA with remap feature.
  - Required modifications to prevent direct access to flash logical addresses when remap is active.
  - Image trailers expected at different offset with remap enabled (see gPlatformMcuBootUseRemap_d in fwk_config.h)
  - fixed image state assessment procedure when in RunCandidate.
- [NVS] Wear statistics counters added
- [SecLib] New feature AES MMO supported for Zigbee
- [Misra] various fixes

6.2.1: KW45/K32W1 MR5 SDK 2.15.000 Experimental Features only:

- Power down on application power domain : Some tests have shown some failure. This feature is not fully supported in this release
- XTAL32K less board with FRO32K support : Some additional stress tests are under progress. Timing variation of the timebase are being analyzed

Major changes

- [RNG]: API updates
  - New compile flag to keep deprecated API: FWK_RNG_DEPRECATED_API
  - change return error code to int type for RNG_Init(), RNG_ReInit()
  - New APIs RNG_GetTrueRandomNumber(), RNG_GetPseudoRandomData()
- [Platform]
  - fwk_platform_sensors
    - Change default temperature value from -1 to 999999 when unknown

  - fwk_platform_genfsk
    - rename from platform_genfsk.c/h to fwk_platform_genfsk.c/h
  - platform family
    - Rename the framework platform folder from kw45_k32w1 to connected_mcu to support other platform from the same family
  - fwk_platform_intflash
    - Moved from fwk_platform files to the new fwk_platform_intflash files the internal flash dependant API
- [NBU]
  - BOARD_LL_32MHz_WAKEUP_ADVANCE_HSLOT changed from 2 to 3 by default
  - BOARD_RADIO_DOMAIN_WAKE_UP_DELAY changed from 0x10 to 0x0F
- [gcc linker]
  - Exclude k32w1_nbu_ble_15_4_dyn.bin from .data section

Minor Changes

- [Platform]
  - PLATFORM_GetTimeStamp(0 has an important fix for reading the Timestamp in TSTMR0
  - New API PLATFORM_TerminateCrypto(), PLATFORM_ResetCrypto() called from SecLib for lowpower exit
  - Fix when enable fro debug callback on nbu
- [DBG]
  - SWO
    - Add new files fwk_debug_swo.c/h to use SWO for debug purpose
    - Two new flags has been added:
      - BOARD_DBG_SWO_CORE_FUNNEL to chose on which core you want to use SWO
      - BOARD_DBG_SWO_PIN_ENABLE to enable SWO on a pin
- [NVS]
  - Add support of NVS and Settings in framework
- [NBU]
  - Fix power down issues and reduce critical section on NBU side:
    - new API PLATFORM_RemoteActiveReqWithoutDelay() called from NBU functions where waiting delay is not required
    - Increase delay needed in power down for OEM part to request the SOC to be active
    - Remove unnecessary code to PLATFORM_RemoteActiveReqWithoutDelay() from PLATFORM_HciRpmsgRxCallback()
    - Improve nbu memory allocation failure debug messages
- [SDK]
  - Multicore: remove critical section in HAL_RpmsgSendTimeout() (only required in FPGA HDI mode)
  - Flash drivers: update for ECC detection

- [Platform]
  - fwk_platform_sensors
    - Fix temperature reporting to NBU
  - fwk_platform_extflash
    - Align .c and .h prototype of PLATFORM_ExternalFlashAreaIsBlank() function
- [NVM]
  - Keep Mutex in NvModuleDeInit(). In Bare metal OS, Mutex can not be destroyed
  - New API NvRegisterEccFaultNotificationCb() to register Notification callback when Ecc error happens in FileSystem
- [MISRA] fixes
  - SecLib_sss.c: ECDH_P256_ComputeDhKey()
  - fwk_platform_extflash.c: PLATFORM_IsExternalFlashPageBlank()
  - fwk_fs_abstraction.c: Various fixes
- [HWparams]
  - Fix on if condition when gHwParamsProdDataPlacementLegacy2IfrMode_c mode is selected
- [OTA]
  - Enable gOtaCheckEccFaults_d by default to avoid bus in case of ECC error during OTA
  - Fix OTA partition overflow during OTA stop and resume transfer
- [BOARD]
  - Place code button or led specific under correct defines in board_comp.c/h
  - Bring back MACROs BOARD_INITRFSWITCHCONTROLPINS in pin_mux header file of the loc board
- [SecLib]
  - Add some undefinition in SecLib_mbedtls_config as new dependency has been added in mbedtls repo:
    - MBEDTLS_SSL_CBC_RECORD_SPLITTING, MBEDTLS_SSL_PROTO_TLS1, MBEDTLS_SSL_PROTO_TLS1_1
- [FRO32K]
  - FRO32K notification callback PLATFORM_FroDebugCallback_t() has new parameter to report he fro_trim value
  - maxCalibrationIntervalMs value can be provided to NBU using PLATFORM_FwkSrvSetRfSfcConfig()
- [Sensors]
  - fix: PLATFORM_GetTemperatureValue() shall have NBU started to send temperature to NBU

6.2.1: RW61x RFP3

- [NVS]
  - Add support of NVS and Settings in framework
- [MISRA] fixes
  - board_lp.c BOARD_UninitDebugConsole() and BOARD_ReinitDebugConsole()

  - fwk_platform_ble.c: Various fixes
- [OTA]
  - Fix OTA partition overflow during OTA stop and resume transfer

6.2.0: RT1060/RT1170 SDK2.15 Major

6.1.8: KW45/K32W1 MR4

- [BOARD PLATFORM]
  - Move gBoardUseFro32k_d to board_platform.h file
  - Offer the possibility to change the source clock accuracy to gain in power consumption
- [BOARD LP]
  - Move PLATFORM_SetRamBanksRetained() at end of BOARD_EnterLowPowerCb() in case a memory allocation is done previously in this function
  - fix low power, increase BOARD_RADIO_DOMAIN_WAKE_UP_DELAY from 0 to 0x10 - Skip this delay when App requesting NBU wakeup
- [PLATFORM]
  - fwk_platform_ble.c/h: New timestamp API that returns the difference between the current value of the LL clock and the argument of the function
  - fwk_platform.c/h:
    * New PLATFORM_EnableEccFaultsAPI_d compile flag: Enable APIs for interception of ECC Fault in bus fault handler
    * New gInterceptEccBusFaults_d compile flag: Provide FaultRecovery() demo code for bus fault handler to Intercept bus fault from Flash Ecc error
- [LOC]
  - Incorrect behavior for set_dtest_page (DqTEST11 overridden)
  - Fix SW1 button wake able on Localization board
  - Fix yellow led not properly initialized
  - Format localization pin_mux.c/h files
- [Inter Core]
  - Affect values to enumeration giving the inter core service message ids
  - Shared memory settings shared between both cores
  - Add callback to register when NBU has unrecoverable Radio issue
- [NVM]
  - Add NV_STORAGE_MAX_SECTORS, NV_STORAGE_SIZE as linker symbol for alignment with other toolchain
  - ECC detection and recovery. New gNvSalvageFromEccFault_d and gNvVerifyReadBackAfterProgram_d compile flags. Please refer to ECC Fault detection section in README.md file located in NVM folder
- [OTA]
  - Prevent bus fault in case of ECC error when reading back OTA_CFR update status (disable by default)
- [SecLib]

  - Shared mutex for RNG and SecLib as they share same hardware resource
- [Key storage]
  - Fix to ignore the garbage at the end of buffers
  - Detect when buffers are too small in KS_AddKey() functions
- [FileCache]
  - Fix deadlock in Filecache FC_Process()
- [SDK]
  - Applications: remove definition of stack location and use default from linker script, fix warmboot stack in freertos at 0x20004000
  - Memory Manager Light:
    * fix Null pointer harfault when MEM_STATISTICS_INTERNAL enable
    * Fix MemReinitBank() on wakeup from lowpower when Ecc banks are turned off

6.1.7: KW45/K32W1 MR3

- [OTA]
  - New API OTA_SetNewImageFlagWithOffset()
  - Fix StorageBitmapSize calculation
  - OTA clean up: Removed OTA_ValidateImage()
- [Low Power]
  - New linker Symbol m_lowpower_flag_start in linker file.
    * Flag is used to indicate NBU that Application domain goes to power down mode. Keep this flag to 0 if only Deep sleep is supported
    * This flag will be set to 1 if Application domain goes to power down mode
  - Re-introduce PWR_AllowDeviceToSleep()/PWR_DisallowDeviceToSleep(), PWR_IsDeviceAllowedToSleep() API
  - Implement tick compensation mechanism for idle hook in a dedicated freertos utils file fwk_freertos_utils.[ch], new functions: FWK_PreIdleHookTickCompensation() and FWK_PostIdleHookTickCompensation
  - Rework timestamping on K4W1
    * PLATFORM_GetMaxTimeStamp() based on TSTMR
    * Rename PLATFORM_GetTimestamp() to PLATFORM_GetTimeStamp()
    * Update PLATFORM_Delay(): Rework to use TSTMR instead of LPTMR for platform_delay
    * Update PLATFORM_WaitTimeout(): Fixed a bug in PLATFORM_WaitTimeout() related to timer wrap
    * Add PLATFORM_IsTimeoutExpired() API
  - Fix race condition in PWR_EnterLowPower(), masking interrupts in case not done at upper layer
  - Low power timer split in new files fwk_platform_lowpower_timer.[ch]
  - New PWR_systicks_bm.c file for bare metal usage: implement SysTick suspend/resume functionality, New weak PWR_SysTicksLowPowerInit()
- [FRO32K]

  - Improve FRO32K calibration in NBU
  - create PLATFORM_InitFro32K() to initialize FRO32K instead of XTAL32K (to be called from hardware_init())
  - update FRO32K README.md file in SFC module
  - Debug:
  - Add Notification callback feature for SFC module FRO32K
  - Linker script update to support m_sfc_log_start in SMU2
- [SecLib]
  - Remove gSecLibSssUseEncryptedKeys_d compile option, split Secure/Unsecure APIs
  - RNG update to use same mutex than SecLib
  - Fix AES_128_CBC_Encrypt_And_Pad length
  - Implement RNG_ReInit() for lowpower
  - Fix issue in ECDH_P256_GenerateKeys() when waking up from power down
  - Call CRYPTO_ELEMU_reset() from SecLib_reInit() for power down support
- [BOARD]
  - Create new board_platform.h file for all Board characteristics settings (32Mhz XTAL, 32KHZ XTAL, etc..)
  - TM_EnterLowpower() TM_EnterLowpower() to be called from LP callbacks
  - Support Localization boards, Only BUTTON0 supported
    * New compile flag BOARD_LOCALIZATION_REVISION_SUPPORT
    * New pin_mux.[ch] files
  - Offer the possibility to override CDAC and ISEL 32MHz settings before the initialization of the crystal in board_platform.h
    * new BOARD_32MHZ_XTAL_CDAC_VALUE, BOARD_32MHZ_XTAL_ISEL_VALUE
    * BOARD_32MHZ_XTAL_TRIM_DEFAULT obsoleted
- [NVM file system]
  - Look ahead in pending save queue - Avoid consuming space to save outdated record
  - Fix NVM gNvDualImageSupport feature in NvIsRecordCopied
- [Inter Core]
  - Change PLATFORM_NbuApiReq() API return parameters granularity from uint32 to uint8
  - MAX_VARIANT_SZ change from 20 to 25
  - Set lp wakeup delay to 0 to reduce time of execution on host side, NBU waits XTAL to be ready before starting execution
  - Update inter core config rpmsg_config.h
  - Add timeout to while loops that relies on hardware in RemoteActiveReq(), Application can register Callbacks when timeout
  - Return non-0 status when calling PLATFORM_FwkSrvSendPacket when NBU non started
  - Let PLATFORM_GetNbuInfo return -10 if response not received on timeout - Doxygen platform_ics APIs
- [HW params]

  - New compile Macro for HW params placement in IFR - Save 8K in FLash: gHwParamsProdDataPlacement_c . 3 modes:
  - Legacy placement, move from legacy to IFR, IFR only placement
  - New compile Macro for Application data to be stored with HW params (in shared flash sector): gHwParamsAppFactoryDataExtension_d, New APIs:
    * Nv_WriteAppFactoryData(), Nv_GetAppFactoryData()
  - See HWParameter.h
- [Platform]
  - Implement PLATFORM_GetIeee802_15_4Addr() API in fwk_platform_ot.c - New gPlatformUseUniqueDeviceIdFor15_4Addr_d compile Macro
  - Wakeup NBU domain when reading RADIO_CTRL UID_LSB register in PLATFORM_GenerateNewBDAddr()
- [Reset]
  - New reset Implementations using Deep power down mode or LVD:
    * new files fwk_platform_reset.[ch]
    * new APIs: PLATFORM_ForceDeepPowerDownReset(), PLATFORM_ForceLvdReset() + reset on ext pins
    * new compile flags: gAppForceDeepPowerDownResetOnResetPinDet_d and gAppForceLvdResetOnResetPinDet_d to reset on external pins
- [FSCI]
  - fix when gFsciRxAck_c enabled
  - integrate new reset APIs

6.1.4: RW610/RW612 RFP1

- [Low Power]
  - Added support of low power for OpenThread stack.
  - Added PWR_AllowDeviceToSleep/PWR_DisallowDeviceToSleep/PWR_IsDeviceAllowedToSleep APIs.
- [platform]
  - Added PLATFORM_GetMaxTimeStamp API.
  - Fixed high impact Coverity.
- [FreeRTOS]
  - Created a new utilities module for FreeRTOS: fwk_freertos_utils.c/h.
  - Implemented a tick compensation mechanism to be used in FreeRTOS idle hook, likely around flash operations. This mechanism aims to estimate the number of ticks missed by FreeRTOS in case the interrupts are masked for a long time.

6.1.4: KW45/K32W1 MR2

- [Low power]
  - Powerdown mode tested and enabled on Low Power Reference Design applications
  - XTAL32K removal functionality using FRO32K, supported from NBU firmwares - limitation: Application domain supports Deep Sleep only (not power down)

  - NBU low power improvement: low power entry sequence improvement and system clock reduction to 16Mhz during WFI
  - Wake up time from cold boot, reset, power switch greatly improved. Device starts on FRO32K, switch to XTAL32K when ready if gBoardUseFro32k_d not set
  - Bug fixes:
    * Move PWR LowPower callback to PLATFORM layers
    * Fix wrong compensation of SysTicks
    * Reinit system clocks when exiting power down mode: BOARD_ExitPowerDownCb(), restore 96MHz clock is set before going to low power
    * Call Timermanager lowpower entry exit callbacks from PLATFORM_EnterLowPower()
    * Update PLATFORM_ShutdownRadio() function to force NBU for Deep power down mode
  - K32W1:
    * Support lowpower mode for 15.4 stacks
- [NVM]
  - New Compilation MACRO gNvDualImageSupport to support multiple firmware image with different register dataset
  - Change default configuration gNvStorageIncluded_d to 1, gNvFragmentation_Enabled_d to 1, gUnmirroredFeatureSet_d to TRUE
  - Some MISRA issues for this new configuration.
  - Remove deprecated functionality gNvUseFlexNVM_d
- [SecLib]
  - New NXP Ultrafast ecp256 security library:
    * New optimized API for ecdh DhKey/ecp256 key pair computation: Ecdh_ComputeDhKeyUltraFast(), ECP256_GenerateKeyPairUltraFast().
    * New macro gSecLibUseDspExtension_d.
    * Improved software version of Seclib with Ultrafast library for ECP256_LePointValid()
  - Bug fixes:
    * Share same mutex between Seclib and RNG to prevent concurrent access to S200
    * Optimized S200 re-initialization, restore ecdh key pair after power down
    * Fixed race condition when power down low power entry is aborted
    * Endianness function updates and clean up
- [OTA]
  - OTASupport improvements:
    * New API OTA_GetImgState(), OTA_UpdateImgState()
    * OTASupport and fwk_platform_extflash API updates for external flash: OTA_SelectExternalStoragePartition(), PLATFORM_IsExternalFlashSectorBlank(), PLATFORM_IsExternalFlashPageBlank(), PLATFORM_OtaGetOtaPartitionConfig()
    * Updated OtaExternalFlash.c, 2 new APIs in fwk_platform_extflash.c

    - Removed unused FLASH_op_type and FLASH_TransactionOpNode_t definitions from public API
    - Removed unused InternalFlash_EraseBlock() from OtaInternalFlash.c
- [NBU firmware]
  - Mechanism to set frequency constraint to controller from the host PLATFORM_SetNbuConstraintFrequency()
  - NbuInfo has one more digit in versionBuildNo field
- [Board]
  - Support Extflash low power mode, add BOARD_UninitExternalFlash(), PLATFORM_UninitExternalFlash(), PLATFORM_ReinitExternalFlash()
  - Support XTAL32K removal functionatity, use FRO32K instead by setting gBoardUseFro32k_d to 1 in board.h file
  - Support localization boards KW45B41Z-LOC Rev C
  - Low power improvement: New BOARD_InitPins() and BOARD_InitPinButtonBootConfig() called from hardware_init.c
  - Removed KW45_A0_SUPPORT support (dcdc)
  - Bug fixes:
    - Fixed glitches on the serial manager RX when exiting from power down
    - Fixed ADC not deinitialized in clock gated modes in BOARD_EnterLowPowerCb()
    - Fixed UART output flush when going to low power: BOARD_UninitAppConsole()
- [platform]
  - PLATFORM_InitBle(), PLATFORM_SendHci() can now block with timeout if NBU does not answer. Application can register callback function to be notified when it occurs: PLATFORM_RegisterBleErrorCallback()
  - Added API to set and get 32Khz XTAL capacitance values: PLATFORM_GetOscCap32KValue() and PLATFORM_SetOscCap32KValue()
  - Added new Service FWK call gFwkSrvNbuMemFullIndication_c to get NBU mem full indication, register with PLATFORM_RegisterNbuMemErrorCallback()
  - Added support negative value in platform intercore service
- [linker script]
  - Realigned gcc linker script with IAR linker script.
  - Added possibility to redefine cstack_start position
  - Added Possibility to change gNvmSectors in gcc linker script
  - Added dedicated reserved Section in shared memory for LL debugging
- [FreeRTOSConfig.h]
  - Removed unused MACRO configFRTOS_MEMORY_SCHEME and configTOTAL_HEAP_SIZE
- [HW Param]
  - Added xtalCap32K field to store XTAL32K triming value
- [fwk_hal_macros.h]
  - Added MACRO for KB, MB and set, clear bits in bit fields
- [Debug]

  - Added MACROs for performance measurement using DWT: DBG_PERF_MEAS

6.1.3 KW45 MR1 QP1

- [Initialization] Delay the switch to XTAL32K source clock until the BLE host stack is initialized
- [lowpower] NBU wakeup from lowpower: configuration can now be programmed with BOARD_NBU_WAKEUP_DELAY_LPO_CYCLE, BOARD_RADIO_DOMAIN_WAKE_UP_DELAY in board.h file
- [NBU firmware] Major fix for NBU system clock accuracy
- [clock_config]
  - Update SRAM margin and flash config when switching system frequency
  - Trim FIRC in HSRUN case
- [XTAL 32K trim] XTAL 32K configuration can be tuned in board.h file with BOARD_32MHZ_XTAL_TRIM_DEFAULT, BOARD_32KHZ_XTAL_CLOAD_DEFAULT, BOARD_32KHZ_XTAL_COARSE_ADJ_DEFAULT
- [MAC address] Add OUI field in PLATFORM_GenerateNewBDAddr() when using Unique Device Id

6.1.2: RW610/RW612 PRC1

- [Low Power]
  - Updates after SDK Power Manager files renaming.
  - Moved PWR LowPower callback to PLATFORM layers.
  - Bug fixes:
    - Fixed wrong compensation of SysTicks during tickless idle.
    - Reinit RTC bus clock after exit from PM3 (power down).
- [OTA]
  - Initial support for OTA using the external flash.
- [platform]
  - Implemented platform specific time stamp APIs over OSTIMER.
  - Implemented platform specific APIs for OTA and external flash support.
  - Removed PLATFORM_GetLowpowerMode API.
  - Added support of CPU2 wake up over Spinel for OpenThread stack.
  - Bug fixes:
    - Fixed issues related to handling CPU2 power state.
- [board]
  - Updated flash_config to support 64MB range.
- [linker script]
  - Fixed wrong assert.

6.1.1: KW45/K32W1 MR1

- [platform] Use new FLib_MemSet32Aligned() to write in ECC RAM bank to force ECC calculation in the MEM_ReinitRamBank() function
- [FunctionLib] Implement new API to set a word aligned
- [platform] Set coarse amplifier gain of the oscilattor 32k to 3
- [platform] Switch back to RNG for MAC Adress generation
- [SecLib] Get rid of the lowpower constraint of deep sleep in ECDH API
- [DCDC] Set DCDC output voltage to 1.35V in case LDO core is set to 1.1V to ensure a drop of 250mV between them
- [NVM] NvIdle() is now returning the number of operations that has been executed
- [documentation] Add markdown of each framework module by default on all package
- [LowPower] Add a delay advised by hardware team on exit of lowpower for SPC
- [SecLib] Rework of SecLib_mbedTLS ECDH functions
- [OTA] Make OTA_IsTransactionPending() public API
- [FunctionLib] Change prototype of FLib_MemCpyWord(), pDst is now a void* to permit more flexibility
- [NVM] Add an API to know if there is a pending operation in the queue
- [FSCI] Fix wrong error case handling in FSCI_Monitor()

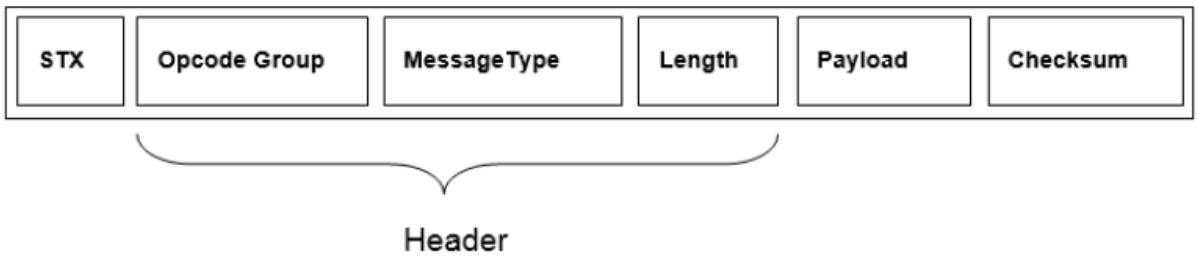
6.1.0: KW45/K32W1 RFP

- [LowPower] Do not call PLATFORM_StopWakeUpTimer() in PWR_EnterLowPower() if PLATFORM_StartWakeUpTimer() was not previously called
- [boards] Add the possibility to wakeup on UART 0 even if it is not the default UART
- [boards] Add support for Hardware flow control for UART0, Enable with gBoardUseUart0HwFlowControl, Pin mux update with two additional API for RTS, CTS pins
- [Sensors] Improve ADC wakeup time from deep sleep state: use save and restore API for ADC context before/after deep sleep state.
- [linker script] update SMU2 shared memory region layout with NBU: increase sqram_btblebuf_size to support 24 connections. Shared memory region moved to the end
- [SecLib] SecLib_DeriveBluetoothSKD() API update to support if EdgeLock key shall be regenerated

6.0.11: KW45/K32W1 PRC3.1

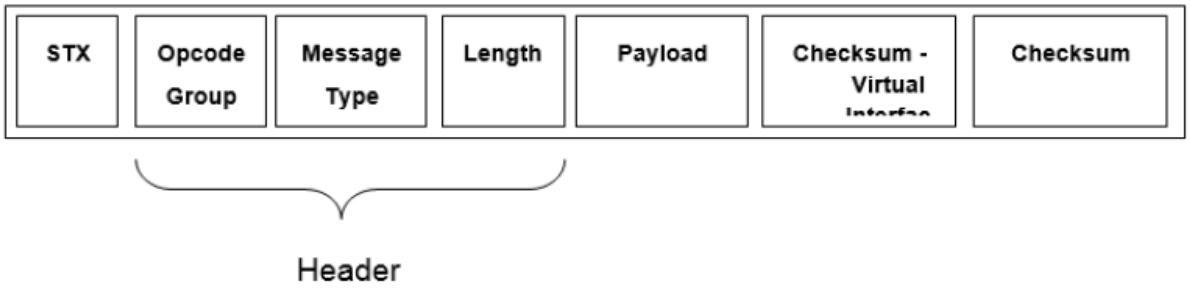
FSCI: Framework Serial Communication Interface

Overview The Framework Serial Communication Interface (FSCI) is both a software module and a protocol that allows monitoring and extensive testing of the protocol layers. It also allows separation of the protocol stack between two protocol layers in a two processing entities setup, the host processor (typically running the upper layers of a protocol stack) and the Black Box application (typically containing the lower layers of the stack, serving as a modem). The Test Tool software is an example of a host processor, which can interact with FSCI Black Boxes at various



layers. In this setup, the user can run numerous commands to test the Black Box application services and interfaces.

The FSCI enables common service features for each device enables monitoring of specific interfaces and API calls. Additionally, the FSCI injects or calls specific events and commands into the interfaces between layers.



An entity which needs to be interfaced to the FSCI module can use the API to register opcodes to specific interfaces. After doing so, any packet coming from that interface with the same opcode triggers a callback execution. Two or more entities cannot register the same opcode on the same interface, but they can do so on different interfaces. For example, two MAC instances can register the same opcodes, one over UARTA, and the other over UARTB. This way, Test Tool can communicate with each MAC layer over two UART interfaces.

The FSCI module executes either in the context of the Serial Manager task or owns its dedicated task if the compilation Macro *gFsciUseDedicatedTask_c* is set to 1.

FSCI packet structure The FSCI module sends and receives messages as shown in the figure below. This structure is not specific to a serial interface and is designed to offer the best communication reliability. The Black Box device expects messages in little-endian format. It also responds with messages in little-endian format.

Below is an illustration of the FSCI packet structure when a virtual interface is used instead :

Field name	Length (bytes)	Description
STX	1	Used for synchronization over the serial interface. The value is always 0x02.
Opcode Group	1	Distinguishes between different Service Access Primitives (for example MLME or MCPS).
Message Type	1	Specifies the exact message opcode that is contained in the packet.
Length	1 or 2	The length of the packet payload, excluding the header and FCS. The length field content must be provided in little-endian format.
Payload	variable	Payload of the actual message.
Checksum	1	Checksum field used to check the data integrity of the packet.
Checksum2	0 or 1	The second CRC field appears only for virtual interfaces.

NOTE : When virtual interfaces are used, the first checksum is decremented with the ID of the interface. The second checksum is used for error detection.

constant definition The following Macro configurs the FSCI module

```
#define gFsciIncluded_c 0 /* Enable/Disable FSCI module */
#define gFsciUseDedicatedTask_c 1 /* Enable Fsci task to avoid recursivity in Fsci module (Misra␣
↪compliant) */
#define gFsciMaxOpGroups_c 8
#define gFsciMaxInterfaces_c 1
#define gFsciMaxVirtualInterfaces_c 0
#define gFsciMaxPayloadLen_c 245 /* bytes */
#define gFsciTimestampSize_c 0 /* bytes */
#define gFsciLenHas2Bytes_c 0 /* boolean */
#define gFsciUseEscapeSeq_c 0 /* boolean */
#define gFsciUseFmtLog_c 0 /* boolean */
#define gFsciUseFileDataLog_c 0 /* boolean */
#define gFsciLoggingInterface_c 1 /* [0..gFsciMaxInterfaces_c) */
#define gFsciHostMacSupport_c 0 /* Host support at MAC layer */
```

The following provides the OpGroups values reserved by MAC, application, and FSCI.

FSCI Host FSCI Host is a functionality that allows separation at a certain stack layer between two entities, usually two boards running separate layers of a stack.

Support is provided for functionality at the MAC layer, for example, MAC/PHY layers of a stack are running as a Black Box on a board, and MAC higher layers are running on another. The higher layers send and receive serial commands to and from the MAC Black Box using the FSCI set of operation codes and groups.

The protocol of communication between the two is the same. The current level of support is provided for:

- FSCI_MsgResetCPUReqFunc – sends a CPU reset request to black box
- FSCI_MsgWriteExtendedAdrReqFunc – configures MAC extended address to the Black Box
- FSCI_MsgReadExtendedAdrReqFunc – N/A

The approach on the Host interfacing a Black Box using synchronous primitives is by default the polling of the FSCI_receivePacket function, until the response is received from the Black Box. The calling task polls whenever the task is being scheduled. This is required because a stack synchronous primitive requires that the response of that request is available in the context of the caller right after the SAP call has been executed.

The other option, available for RTOS environments, is using an event mechanism. The calling task blocks waiting for the event that is sent from the Serial Manager task when the response is available from the Black Box. This option is disabled by default. The disadvantage of this option is that the primitive cannot be received from another Black Box through a serial interface because the blocked task is the Serial Manager task, which reaches a deadlock as cannot be released again.

FSCI ACK ACK transmission is enabled through the gFsciTxAck_c macro definition. Each FSCI valid packet received triggers an FSCI ACK packet transmission on the same FSCI interface that the packet was received on. The serial write call is performed synchronously to send the ACK packet before any other FSCI packet. Only then the registered handler is called to process the received packet. The ACK is represented by the gFSCI_CnfOpcodeGroup_c and mFsciMsgAck_c Opcode. An additional byte is left empty in the payload so that it can be used optionally as a packet identifier to correlate packets and ACKs. ACK reception is the other component that is enabled through gFsciRxAck_c. The behavior is such that every FSCI packet sent through a serial

interface triggers an FSCI ACK packet reception on the same interface after the packet is sent. If an ACK packet is received, the transmission is considered successful. Otherwise, the packet is resent a number of times. The ACK wait period is configurable through mFsciRxAckTimeoutMs_c and the number of transmission retries through mFsciTxRetryCnt_c. The ACK mechanism described above can also be coupled with a FSCI packet reception timeout enabled through gFsciRxTimeout_c and configurable through mFsciRxRestartTimeoutMs_c. Whenever there are no more bytes to be read from a serial interface, a timeout is configured at the predefined value if no other bytes are received. If new bytes are received, the timer is stopped and eventually canceled at successful reception. However, if, for any reason, the timeout is triggered, the FSCI module considers that the current packet is invalid, drops it, and searches for a new start marker.

FSCI usage example Detailed data types and APIs are described in ConnFWK API documentation.

Initialization

```
/* Configure the number of interfaces and virtual interfaces used */
#define gFsciMaxInterfaces_c 4
#define gFsciMaxVirtualInterfaces_c 2
....
/* Define the interfaces used */
static const gFsciSerialConfig_t myFsciSerials[] = {
    /* Baudrate, interface type, channel No, virtual interface */ {gUARTBaudRate115200_c, gSerialMgrUart_
↪c, 1, 0}, {gUARTBaudRate115200_c, gSerialMgrUart_c, 1, 1}, {0 , gSerialMgrIICSlave_c, 1, 0}, {0 ,␣
↪gSerialMgrUSB_c, 0, 0},
};
....
/* Call init function to open all interfaces */
FSCI_Init( (void*)mFsciSerials );
```

Registering operation groups

```
myOpGroup = 0x12; // Operation Group used
myParam = NULL; // pointer to a parameter to be passed to the handler function (myHandlerFunc)
myInterface = 1; // index of entry from myFsciSerials
...
FSCI_RegisterOpGroup( myOpGroup, gFsciMonitorMode_c, myHandlerFunc, myParam, myInterface );
```

Implementing handler function

```
void fsciMcpsReqHandler(void *pData, void* param, uint32_t interfaceId)
{
    clientPacket_t *pClientPacket = ((clientPacket_t*)pData);
    fsciLen_t myNewLen;
    switch( pClientPacket->structured.header.opCode )
    {
        case 0x01:
        {
            /* Reuse packet received over the serial interface The OpCode remains the same. The length of the␣
↪response must be <= that the length of the received packet */
            pClientPacket->structured.header.opGroup = myResponseOpGroup;/* Process packet */
            ...
            pClientPacket->structured.header. len = myNewLen;
            FSCI_transmitFormatedPacket(pClientPacket, interfaceId);
            return;
        }
        case 0x02:
        {
```

(continues on next page)

(continued from previous page)

```
        /* Alocate a new message for the response. The received packet is Freed */
        clientPacket_t *pResponsePkt = MEM_BufferAlloc( sizeof(clientPacketHdr_t) + myPayloadSize_d␣
↪+ sizeof(uint8_t) // CRC);
        if(pResponsePkt)
        {
            /* Process received data and fill the response packet */ ...
            pResponsePkt->structured.header. len = myPayloadSize_d;
            FSCI_transmitFormatedPacket(pClientPacket, interfaceId);
        }
        break;
    }
    default:
        MEM_BufferFree( pData );
        FSCI_Error( gFsciUnknownOpcode_c, interfaceId );
        return;
  }
  /* Free message received over the serial interface */
  MEM_BufferFree( pData );
}
```

Helper Functions Library

Overview This framework provides a collection of features commonly used in embedded software centered on memory manipulation.

HWParameter: Hardware parameter

Production Data Storage Hardware parameters provide production data storage

Overview Different platforms/boards need board/network node-specific settings to function according to the design. (Examples of such settings are IEEE® addresses and radio calibration values specific to the node.) For this purpose, the last flash sector is reserved and contains hardware-specific parameters for production data storage. These parameters pertain to the network node as a distinct entity. For example, a silicon mounted on a PCB in a specific configuration, rather than to just the silicon itself. This sector is reserved by the linker file, through the PROD_DATA section and it should be read/written only through the API described below.

> Note : This sector is not erased/written at code download time and it is not updated via over-the-air firmware update procedures to preserve the respective node-specific data, regardless of the firmware running on it.

Constant Definitions Name :

```
extern uint32_t PROD_DATA_BASE_ADDR[];
```

Description :

This symbol is defined in the linker script. It specifies the start address of the PROD_DATA section.

Name :

```
static const uint8_t mProdDataIdentifier[10] = {"PROD_DATA:"};
```

Description :

The value of this constant is copied as identification word (header) at the beginning of the PROD_DATA area and verified by the dedicated read function.

Note: the length of mProdDataIdentifier imposes the definition of PROD_DATA_ID_STRING_SZ as 10. The legacy HW parameters structure provides headroom for future usage. There are currently 63 bytes available.

Data type definitions Name :

```
typedef PACKED_STRUCT HwParameters_tag
{
    uint8_t identificationWord[PROD_DATA_ID_STRING_SZ]; /* internal usage only: valid data present */
    /*@{*/
    uint8_t bluetooth_address[BLE_MAC_ADDR_SZ];      /*!< Bluetooth address */
    uint8_t ieee_802_15_4_address[IEEE_802_15_4_SZ]; /*!< IEEE 802.15.4 MAC address - K32W1 only
↪*/
    uint8_t xtalTrim;                                /*!< XTAL 32MHz Trim value */
    uint8_t xtalCap32K;                               /*!< XTAL 32kHz capacitance value */
    /* For forward compatibility additional fields may be added here
       Existing data in flash will not be compatible after modifying the hardwareParameters_t typedef.
       In this case the size of the padding has to be adjusted.
    */
    uint8_t reserved[1];
    /* first byte of padding : actual size if 63 for legacy HwParameters but
      complement to 128 bytes in the new structure */
}
hardwareParameters_t;
```

Description:

Defines the structure of the hardware-dependent information.

> Note : Some members of this structure may be ignored on a specific board/silicon configuration. Also, new members may be added for implementation-specific purposes and the backward compatibility must be maintained.

The CRC calculation starts from the reserved field of the hardwareParameters_t and ends before the hardwareParamsCrc field. Additional members to this structure may be added using the following method :

Add new fields before the reserved field. This method does not cause a CRC fail, but you must keep in mind to subtract the total size of the new fields from the size of the reserved field. For example, if a field of uint8_t size is added using this method, the size of the reserved field shall be changed to 63.

Co-locating application factory data in HW Parameters flash sector. The sector containing the Hardware parameter structure may be located in the internal flash, usually at its last sector. The actual Hardware parameter structure has a size of 128 bytes - including padding reserved for future use. Since there is plenty of room available in a flash sector (4kB or 8kB), co-locating Application Factory Data in the same structure prevents from reserving another flash sector for these data. The application designer may adopt this solution by defining gHwParamsAppFactoryDataExtension_d as 1. A total of 2kB is alloted to this purpose.

If this option was chosen, whenever any of the Hardware parameter fields is modified, its CRC16 will change so the sector will need erasing. The gHwParamsAppFactoryDataPreserveOnHwParamUpdate_d compilation option deals with restoring the contents of the App Factory Data. Nonetheless this requires a temporary allocation a 2kB buffer to preserve the previous content and restore then on completion of the Hw Parameter update.

Special reserved area at start of IFR1 in range [0x02002000..0x02002600[On development boards a 1536 byte area is reserved and the actual Hardware parameter area begins at offset 0x600. Preserving this area on a HW parameter update also requires a temporary 1.5kB dynamic allocation (in addition to the App Factory 2kB allocation), to be able to restore on completion of update operation.

HW Parameters Production Data placement options The placement of production data (PROD_DATA) can be selected based on the definition of gHwParamsProdDataPlacement_c (see fwk_config.h). The productions data seldom need update for final products, once calibration data, MAC addresses or others have been programmed. Two cases exist, plus a transition mode :

1) gHwParamsProdDataMainFlashMode_c (0) :
   - PROD_DATA are located at top of Main Flash. Hardware parameters section is placed in the last sector of internal flash [0xfe000..0x100000[.
   - The linker script must reserve this area explicitly so as to prevent placement of NVM or text sections at that location by setting gUseProdInfoMainFlash_d.
2) gHwParamsProdDataMainFlash2IfrMode_c(1) : - PROD_DATA are located in IFR1, but MainFlash version still exists during interim period. - If the contents of the PROD_DATA section in MainFlash is valid (not blank and correct CRC) but the IFR PROD_DATA is still blank, copy the contents of MainFlash PROD_DATA to IFR location. - When done PROD_DATA in IFR are used. Once the transition is done, an application using (2: gHwParamsProdDataPlacementIfrMode_c) may be programmed.
3) gHwParamsProdDataIfrMode_c (2) :
   - PROD_DATA section dwells in the IFR1 sector [0x02002000..0x02004000[
   - in development phase the area comprised between [0x02002000..0x02002600[must be reserved for internal purposes.
   - This allows to free up the top sector of Main Flash by linking with gUseProdInfoMainFlash_d unset.

LowPower

Low Power reference user guide This Readme file describes the connectivity software architecture and provides the general low power enablement user guide.

1- Connectivity Low Power SW architecture The connectivity low power software architecture is composed of various components. These are described from the lower layer to the application layer:

1. The SDK power manager in component/power_manager. This component provides the basic low power framework. It is not specific to the connectivity but generic across devices. it covers:
   - gather the low power constraints for upper layer and take the decision on the best suitable low power state the device is allowed to go to fullfill the constraints.
   - call the low power entry and exit function callbacks
   - call the appropriate SW routines to switch the device into the suitable low power state
2. Connectivity Low power module in the connectivity framework. This module is composed of:

- The low power service called PWR inside framework/LowPower (this folder), This module is generic to all connectivity devices.
- The platform lowpower: fwk_platform_lowpower.[ch] located in framework\platform\<platform_name>. These files are a collection of low power routines functions for the PWR module and upper layer. These are specific to the device.

  Both PWR and platform lowpower files are detailed in section below.

3. Low power Application modules, it consists of 3 parts:
   - Application initialization file app_services_init.c where the application initializes the low power framework, see next section 'Demo example for typical usage of low power framework'
   - Application Idle task from application to call the main low power entry function PWR_EnterLowPower() to switch the device into lowpower. This function is application specific, one example is given in the section 1.3.3
   - Low power board files : board_lp.[ch] located in board/lowpower. These files implement the low power entry and exit functions related to the application and board. Customers shall modify these files for their own needs. Example code is given for the connectivity applications.

     User guide is provided in section 1.3 below.

   Note : Linker script may also be impacted for power down mode support in order to provide an RAM area for ROM warm boot (depends on the platform) and application warmboot stack

The Low power central and master reference design applications provide an example of Low power implementation for BLE. Customer can also refer to the associated document 'low power connectivity reference design user guide'.

1.1 - SDK power manager This module provides the main low power functionalities such as:

- Decide the best low-power mode dependent on the constraints set by upper layers by using PWR_SetLowPowerModeConstraints() API function.
- Handle the sequences to enter and exit low-power mode.
- Enable and configure wake up sources, call the application callbacks on low power entry/exit sequences.

The SDK power manager provides the capability for application and all components to receive low power constraints to the power. The Application does not set the low-power mode the device shall go into. When going to low power, the SDK power manager selects the best low-power mode that fits all the constraints.

As an example, if the low power constraint set from Application is Power Down mode, and no other constraint is set, the SDK power manager selects Power down mode, the next time the device enters low power. However, if a new constraint is set by another component, such as the SecLib module that operates Hardware encryption, the SecLib module would select WFI as additional low power constraint. Also, the SDK power manager selects this last low-power mode until the constraint is released by the SecLib module. It then reselects Power Down mode for further low power entry modes.

1.2 - PWR Low power module The PWR module in the connectivity framework provides additional services for the connectivity stacks and applications on top of the SDK power manager.

It also provides a simple API for Connectivity Stack and Connectivity applications.

However, more advanced features such as configuring the wake-up sources are only accessible from the SDK Power Manager API.

In addition to the SDK Power Manager, the PWR module uses the software resources from lower level drivers but is independent of the platform used.

1.2.1 - Functional description Initialization of the PWR module should be done through PWR_Init() function. This is mainly to initialize the SDK power manager and the platform for low power. It also registers PWR low power entry/exit callback PWR_LowpowerCb() to the SDK power manager. This function will be called back when entering and exiting low power to perform mandatory save/restore operations for connectivity stacks. The application can perform extra optional save/restore operations in the board_lp file where it can register to the SDK Power Manager its own callback. This is usually used to handle optional peripherals such as serial interfaces, GPIOs, and so on.The main entry function is PWR_EnterLowPower(). It should be called from Idle task when no SW activity is required. The maximum duration for lowpower is given as argument timeoutUs in useconds. This function will check the next Hardware event in the connectivity stack, typically the next Radio activity. A wakeup timer is programmed if the timeoutUs value is shorter than the next radio event timing. Passing a timeout of 0us will be interpreted as no timeout on the application side.

On device wakeup from low power state, the function will return the time duration the device has been in low power state.

Two APi are provided to set and release low power state constraints : PWR_SetLowPowerModeConstraint() and PWR_ReleaseLowPowerModeConstraint(). These are helper functions. User can use directly the SDK power manager if needed.

The PWR module also provides some API to be set as callbacks into other components to prevent from going to low power state. It can be used in following examples :

1. If a DMA is running, the module in charge of the DMA would need to set a constraint to avoid the system from going to a low power state when the RAM and system bus are no longer available.
2. If transfer is going on a peripheral, the drivers shall set a constraint to forbid low power mode.
3. If encryption is on going through an Hardware accelerator, the HW accelerator and the required ressources (clocks, etc), shall be kept active also by setting a constraints.

1.2.2 - Tickless mode support This module also provides some routines functions PWR_SysticksPreProcess() and PWR_SysticksPostProcess() from PWR_systicks.c in order to support the tickless mode when using FreeRTOS. The tickless mode is the capability to suspend the periodic system ticks from FreeRTOS and keep timebase tracking using another low power counter. In this implementation, the Timer Manager and time_stamp component are used for this purpose.

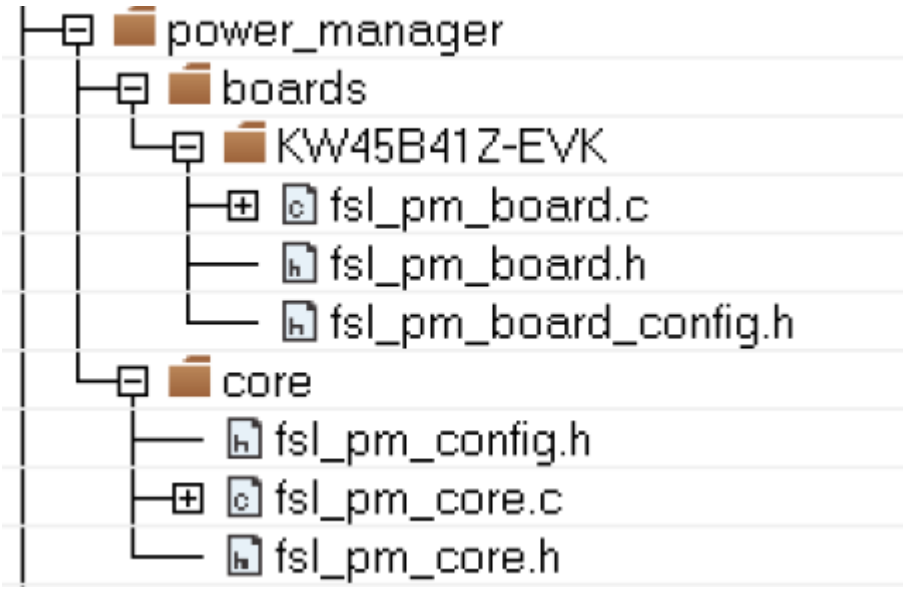
Idle task shall call these functions PWR_SysticksPreProcess() and PWR_SysticksPostProcess() before and after the call to the main low power entry function PWR_EnterLowPower().

Refer to framework/LowPower/PWR_systicks.c file or section 2.1 below for more information.

1.3 - Low power platform submodule Low power platform module file fwk_platform_lowpower.c provides the necessary helper functions to support low power device initialization, device entry, and exit routines. These are platform and device specific. Typically, the PWR module uses the low power platform submodule for all low power specific routines.

The low power platform submodule is documented in the Connectivity Framework Reference Manual document and in the Connectivity Framework API document.

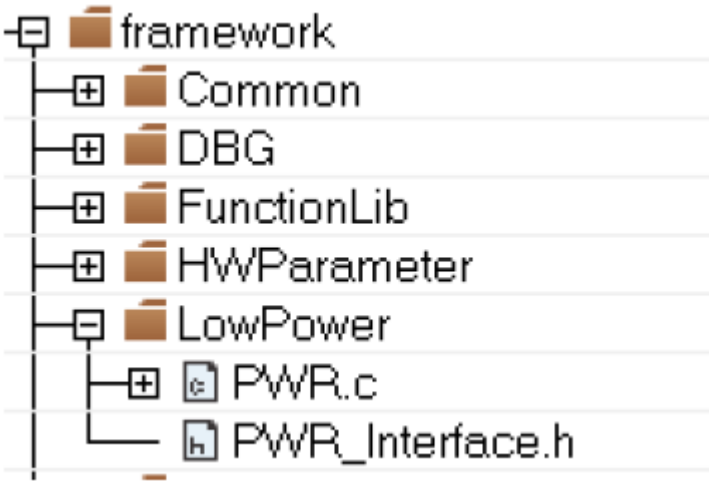
1.4 - Low power board files Low power board files board_lp.[ch] are both application and board specific. Users should update this file to add new functions to include new used peripherals that require low power support. In the current SDK package, only Serial Manager over UART and button (IO toggle wake up source) are supported and demonstrated in the Bluetooth LE demo application.



Other peripherals that require specific action on low power entry and restore on low power exit should be added to low power board files. For more details, refer to section Low power board file update

2 - Low power Application user guide This section provides a user guide to enable Low power on a connectivity application, It gives example of typical implementation for the initialization, Idle task function and low power entry/exit functions.

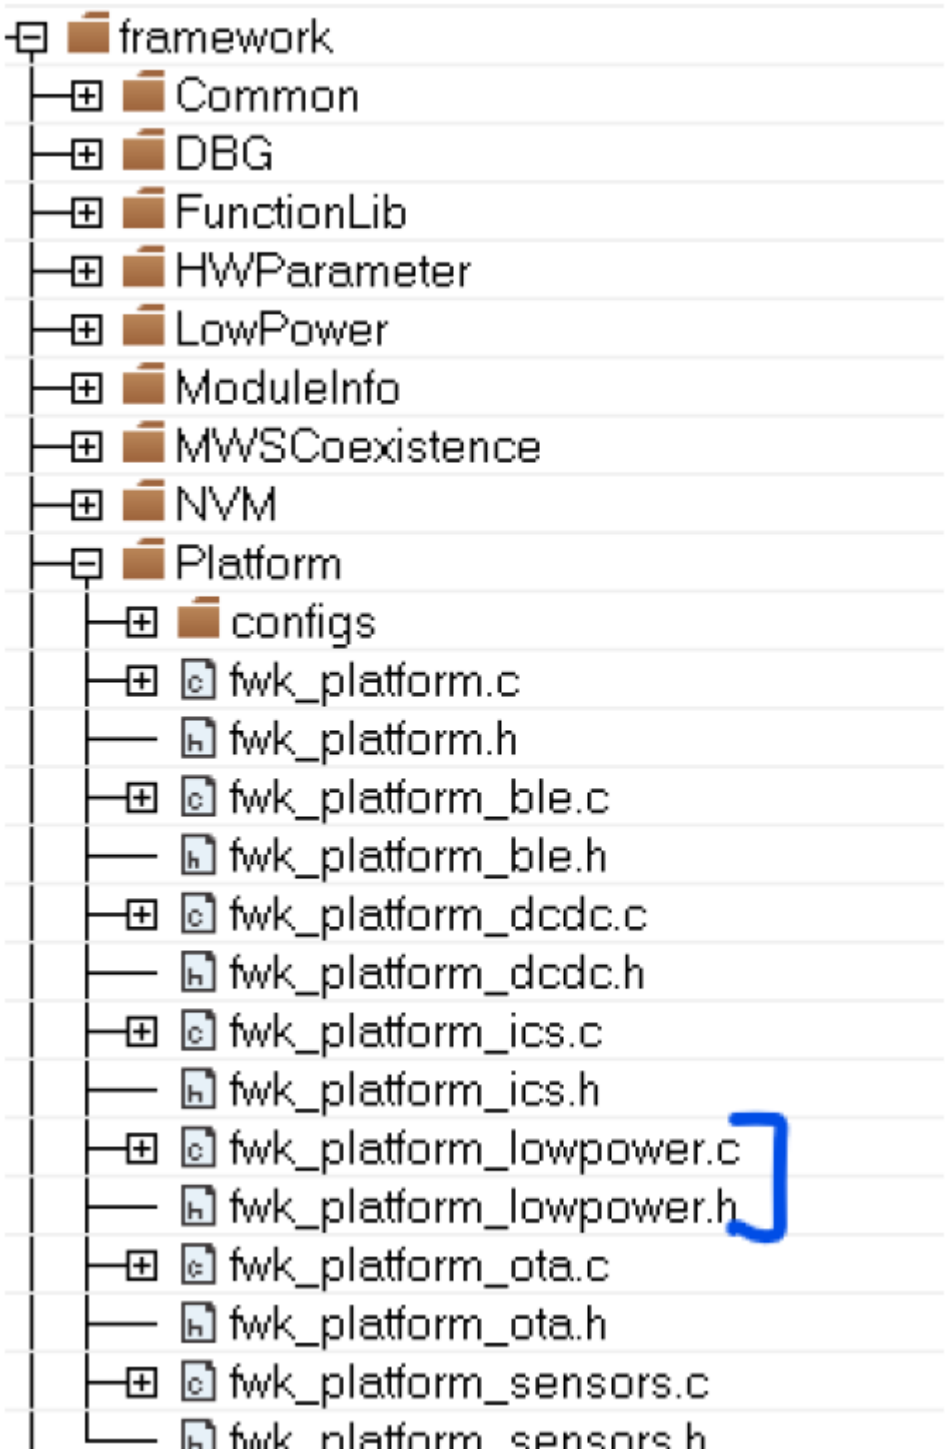
2.1 - Application Project updates It is recommended to reuse the low-power peripheral/central reference design application projects as a start. This ensures that everything is in place for the low-power optimization feature. Then, application files may be added to one of the two projects.



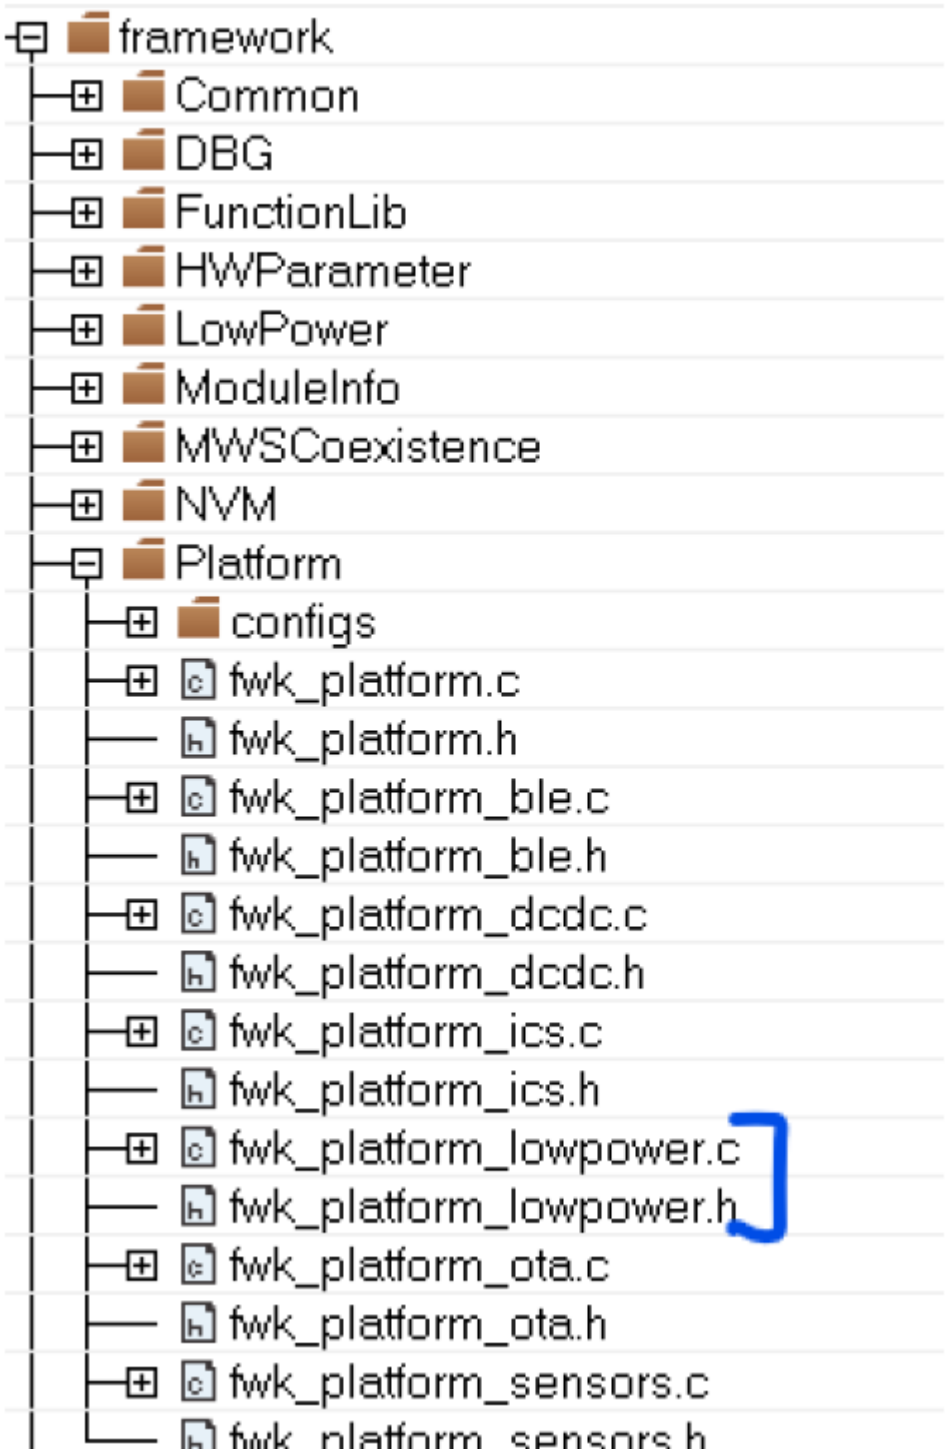
However, users can start directly from the application project and implement low power in it, by performing the steps described in the following sections.

2.1.1 - SDK Power Manager Most of the Low power functionality is implemented in the SDK Power Manager. The files to add into the project SDK power_manager module are listed in the figure below:

You need to use the files located in the folder that match your device.



2.1.2 - PWR connectivity framework module PWR.c PWR_Interface.h shall be added to your application projects :



Optionally, in order to support Systick less mode, PWR_systicks.c or PWR_systicks_bm.c could also be added.

The include path to add is: middleware/wireless/framework/LowPower

2.1.3 -Low power platform submodule Low power platform files can be found in the 'Platform' module in the connectivity framework:

2.1.4 - Low power board files These files are located in the same folder that the other board files board.[ch]. Hence, it is not required to add any new include path at compiler command line.

2.1.5 - Application RTOS Idle hook and tickeless hook functions See section 2.4.3 Idle task implementation example

2.2 - Low power and wake up sources Initialization Low power initialization and configuration are performed in APP_ServiceInitLowpower()function. This is called from APP_InitServices() function called from the main() function so all is already set up when calling the main application entry point, typically BluetoothLEHost_AppInit() function in the Bluetooth LE demo applications.

The default Low Power mode configured in APP_InitServices() is Deep Sleep mode. In Bluetooth

LE, (or any other stack technology), Deep Sleep mode fits for all use cases. For instance, for Bluetooth LE states: Advertising, Connected, Scanning states. This mode already performs a very good level of power saving and likely, this is not required to optimize more if the device is powered from external supply.

APP_ServiceInitLowpower() function performs the following initialization and configuration:

- Initialize the Connectivity framework Low power module PWR_Init(), this function initialized the SDK power manager.
- Configure the wakeup sources such as serial manager wake up source for UART, or button for IO wake up configuration. These are typical wakeup sources used in the connectivity application. Developer may want to add additional wake up sources here specific for the application.

  Note : The low power timer wakeup source and wakeup from Radio domain are directly enabled from the Connectivity framework Low power module PWR as it is mandatory for the connectivity stack. If your application supports other peripherals (such as i2c, spi, and others) that require wake sources from low power, developer should add additional wake up sources setting in this function APP_ServiceInitLowpower(). The complete list of wakeup sources are available from the SDK power manager component, see file fsl_pm_board.h in component/boards/<device_name>/.
- Initialize and register the Low power board file used to register and implement low power entry and exit callback function used for peripheral. This is done by calling the BOARD_LowPowerInit() function.
- Register low power Enter and exit critical function to driver component to enable / disable low power when the Hardware is active. Example is given for serial manager that needs to disable low power when the TX ring buffer contains data so the device does not enter low power until the buffer is empty.

Finally, APP_ServiceInitLowpower() function configures the Deep Sleep mode as the default low power constraint for the application. It is recommended to keep this level of low power constraint during all the connectivity stack initialization.

Example of low power framework initialization can be found in app_services_init.c file. Below is some code example for initializing the low power framework and wake up sources:

```
static void APP_ServiceInitLowpower(void)
{
    PWR_ReturnStatus_t status = PWR_Success;

    /* It is required to initialize PWR module so the application
     * can call PWR API during its init (wake up sources...) */
    PWR_Init();

    /* Initialize board_lp module, likely to register the enter/exit
     * low power callback to Power Manager */
    BOARD_LowPowerInit();

    /* Set Deep Sleep constraint by default (works for All application)
     *   Application will be allowed to release the Deep Sleep constraint
     *   and set a deepest lowpower mode constraint such as Power down if it needs
     *   more optimization */
    status = PWR_SetLowPowerModeConstraint(PWR_DeepSleep);
    assert(status == PWR_Success);

#if (defined(gAppButtonCnt_c) && (gAppButtonCnt_c > 0))

    /* Init and enable button0 as wake up source
     * BOARD_WAKEUP_SOURCE_BUTTON0 can be customized based on board configuration
```

(continues on next page)

(continued from previous page)

```
    * On EVK we use the SW2 mapped to GPIOD */
   PM_InitWakeupSource(&button0WakeUpSource, BOARD_WAKEUP_SOURCE_BUTTON0, NULL,␣
↪true);
#endif

#if (gAppButtonCnt_c > 1)
   /* Init and enable button1 as wake up source
    * BOARD_WAKEUP_SOURCE_BUTTON1 can be customized based on board configuration
    * On EVK we use the SW3 mapped to PTC6 */
   PM_InitWakeupSource(&button1WakeUpSource, BOARD_WAKEUP_SOURCE_BUTTON1, NULL,␣
↪true);
#endif

#if (defined(gAppUseSerialManager_c) && (gAppUseSerialManager_c > 0))

#if defined(gAppLpuart0WakeUpSourceEnable_d) && (gAppLpuart0WakeUpSourceEnable_d > 0)
   /* To be able to wake up from LPUART0, we need to keep the FRO6M running
    * also, we need to keep the WAKE domain is SLEEP.
    * We can't put the WAKE domain in DEEP SLEEP because the LPUART0 is not mapped
    * to the WUU as wake up source */
   (void)PM_SetConstraints(PM_LP_STATE_NO_CONSTRAINT, APP_LPUART0_WAKEUP_
↪CONSTRAINTS);
#endif

   /* Register PWR functions into SerialManager module in order to disable device lowpower
      during SerialManager processing. Typically, allow only WFI instruction when
      uart data are processed by serail manager  */
   SerialManager_SetLowpowerCriticalCb(&gSerMgr_LowpowerCriticalCBs);
#endif

#if defined(gAppUseSensors_d) && (gAppUseSensors_d > 0)
   Sensors_SetLowpowerCriticalCb(&app_LowpowerSensorsCriticalCBs);
#endif

   (void)status;
}
```

2.3 - low power entry/exit sequences : board files updates Board Files that handles low-power are board_lp.[ch] files.

Low power board files implement the low-power callbacks of the peripherals to be notified when entering or exiting Low Power mode. This module also registers these low-power callbacks to the SDK Power Manager component to get the notifications when the device is about to enter low-power or exit Low Power mode. The Low-power callbacks are registered from BOARD_LowPowerInit() function. This function is called from app_services_init.c file after PWR module initialization.

The low power callback functions can be categorized in two groups:

- Entry Low power call back functions: These are usually used to prepare the peripherals to enter low-power. For example, they can be used for flushing FIFOs, switching off some clocks, and reconfiguring pin mux to avoid leakage on pins. In case of Power Down mode, these functions could be used to save the Hardware peripheral context.
- Exit Low power call back functions: These are typically used to restore the peripherals to functionality. Therefore, they perform the reverse of what is done by the entry call-back functions: restoring the pin mux, re-enabling the clock, in case of Power Down mode, restoring the Hardware peripheral context, and so on.

Note that distinction can be done between clock gating mode (Deep Sleep mode), and power gated mode (Power down mode) when entering and exiting Low Power mode. The

BOARD_EnterLowPowerCb() and BOARD_ExitLowPowerCb() functions provide the code to call the various peripheral entry and exit functions to go and exit Deep Sleep mode: serial manager, button, debug console, and others.

However, the processing to save and restore the Hardware peripheral is implemented in different functions BOARD_EnterPowerDownCb() and BOARD_ExitPowerDownCb(). These two functions should be called when exiting power gated modes of the power domain. These two should implement specific code for such case (likely the complete reinitialization of each peripheral). In order to know the Low Power mode that the wake up domain, or main domain has been entered, the low-power platform API PLATFORM_GetLowpowerMode() can be called.

> **Note :** BOARD_ExitPowerDownCb() is called before BOARD_ExitLowPowerCb() as it is generally required to restore the Hardware peripheral contexts before reconfiguring the pin mux to avoid any signal glitches on the pads

Also, It is important to know whether the location of the Hardware peripheral is in the main domain or wake up domain. The two power domains can go into different power modes with the limitation that the wakeup domain cannot go to a deepest Low Power mode than the main domain. Depending on the constraint set on SDK power manager, the wake up domain could remain in active while the main domain can go to deep sleep or power down modes. In this case, the peripherals in the wake up domain does not required to be restored, as explained in the section Power Down. Likely, only pin mux reconfiguration is required in this case.

example Low power entry and exit functions shall be registered to the SDK power manager so these functions will be called when the device will enter and exit low power mode. This is done by BOARD_LowPowerInit() typically called from application source code in app_services_init.c file

```
static pm_notify_element_t boardLpNotifyGroup = {
    .notifyCallback = BOARD_LowpowerCb,
    .data           = NULL,
};

void BOARD_LowPowerInit(void)
{
    status_t status;

    status = PM_RegisterNotify(kPM_NotifyGroup2, &boardLpNotifyGroup);
    assert(status == kStatus_Success);
    (void)status;
}
```

BOARD_LowpowerCb() callback function will handle both the entry and exit sequences. An argument is passed to the function to indicate the lowpower state the device enter/exit. Typical implementation is given below. Customer shall make sure to differentiate low power entry and exit, and the various low power states.

Typically, nothing is expected to be done if low power state is WFI or Sleep mode. These modes are some light low power states and the system can be woken up by interrupt trigger.

In Deep sleep mode, the clock tree and source clocks are off, the system needs to be woken up from an event from the WUU module.

In Power down mode, some peripherals are likely to be powered off, context save and restore may need to be done in these functions.

```
static status_t BOARD_LowpowerCb(pm_event_type_t eventType, uint8_t powerState, void *data)
{
    status_t ret = kStatus_Success;
    if (powerState < PLATFORM_DEEP_SLEEP_STATE)
    {
        /* Nothing to do when entering WFI or Sleep low power state
           NVIC fully functionnal to trigger upcoming interrupts */
```

(continues on next page)

(continued from previous page)

```
    }
    else
    {
        if (eventType == kPM_EventEnteringSleep)
        {
            BOARD_EnterLowPowerCb();

            if (powerState >= PLATFORM_POWER_DOWN_STATE)
            {
                /* Power gated low power modes often require extra specific
                 * entry/exit low power procedures, those should be implemented
                 * in the following BOARD API */
                BOARD_EnterPowerDownCb();
            }
        }
        else
        {
            /* Check if Main power domain domain really went to Power down,
             *   powerState variable is just an indication, Lowpower mode could have been skipped by an␣
↪immediate wakeup
             */
            PLATFORM_PowerDomainState_t main_pd_state = PLATFORM_NO_LOWPOWER;
            PLATFORM_status_t           status;

            status = PLATFORM_GetLowpowerMode(PLATFORM_MainDomain, &main_pd_state);
            assert(status == PLATFORM_Successful);
            (void)status;

            if (main_pd_state == PLATFORM_POWER_DOWN_MODE)
            {
                /* Process wake up from power down mode on Main domain
                 *  Note that Wake up domain has not been in power down mode */
                BOARD_ExitPowerDownCb();
            }

            BOARD_ExitLowPowerCb();
        }
    }
    return ret;
}
```

2.4 - Low power constraint updates and optimization Except for the board file update as seen in previous section, the application does not need any other changes for low-power support in Deep Sleep mode. It shall work as if no low-power is supported. However, If more aggressive power saving is required, this constraint can be changed in your application in order to further reduce the power consumption in Low Power mode.

2.4.1 - Changing the Default Application low power constraint after firmware initialization The Low power reference design applications (central or peripheral) provides demonstration on how to change the Application low power constraint. In the Application main entry point BluetoothLEHost_AppInit(), Deep Sleep mode is configured by default from APP_ServiceInitLowpower() function.

> **Note :** It is recommended to keep Deep Sleep mode as default during all the stack initialization phase until BluetoothLEHost_Initialized() and BleApp_StartInit() functions are called. In case of Bonded device with privacy, it is recommended to wait for gControllerPrivacyStateChanged_c event to be called.

BleApp_LowpowerInit() function provides an example of code on how to release the default Deep sleep low-power constraint and set a new constraint such as Power down mode for the application. This deeper low-power mode is used when no Bluetooth LE activity is on going, and if no other higher Low-power constraint is set by another components or layer. For instance, if some serial transmission is on going by the serial manager, or if the SecLib module has on going activity on the HW crypto accelerator, the low-power mode could less deep.

```
static void BleApp_LowpowerInit(void)
{
#if defined(gAppLowpowerEnabled_d) && (gAppLowpowerEnabled_d>0)
    PWR_ReturnStatus_t status;

    /*
     * Optionally, Allow now Deepest lowpower mode constraint given by gAPP_
↪LowPowerConstraintInNoBleActivity_c
     *    rather than DeepSleep mode.
     * Deep Sleep mode constraint has been set in APP_InitServices(), this is fine
     *    to keep this constraint for typical lowpower application but we want the
     *    lowpower reference design application to be more agressive in term of power saving.

     *   To apply a lower lowpower mode than Deep Sleep mode, we need to
     *    - 1) First, release the Deep sleep mode constraint previously set  by default in app_services_init()
     *    - 2) Apply new lowpower constraint when No BLE activity
     *   In the various BLE states (advertising, scanning, connected mode), a new Lowpower
     *    mode constraint will be applied depending of Application Compilation macro set in app_preinclude.
↪h :
     *    gAppPowerDownInAdvertising, gAppPowerDownInConnected, gAppPowerDownInScanning
     */

    /*  1) Release the Deep sleep mode constraint previously set  by default in app_services_init() */
    status = PWR_ReleaseLowPowerModeConstraint(PWR_DeepSleep);
    assert(status == PWR_Success);
    (void)status;

    /*  2) Apply new Lowpower mode constraint gAppLowPowerConstraintInNoBleActivity_c *
     *      The BleAppStart() call above has already set up the new lowpower constraint
     *       when Advertising request has been sent to controller        */
    BleApp_SetLowPowerModeConstraint(gAppLowPowerConstraintInNoBleActivity_c);
#endif
}
```

2.4.2 - Changing the Application lowest low power constraint during application execution

In the various application use cases, (in the various Bluetooth LE activity states, advertising, connected, scanning), some lower low-power constraint can be set, as Power down for advertising, Deep Sleep for connected, or Scanning. Customer can change the level of Low Power mode in the various use case mainly depending of the time duration the device is supposed to remain in low-power. The longer the time that the device remains in low power, the higher the benefit for a deeper Low Power mode such as Power down mode. However, please note that the wake up from power down mode takes significantly more time than deep sleep as ROM code is re executed and the hardware logic needs to be restored. Sections Deep Sleep and Power Down provide some guidance on when to use Deep Sleep mode or Power Down modes respectively.

In the low power reference design applications, four application compilations macros are defined to adjust the low-power mode into advertising, scanning, connected, or no Bluetooth LE activity. Other use cases can be added as desired. For instance, If application needs to run a DMA transfer, or if application needs to wakeup regularly to process data from external device, it may be useful to set WFI constraint (in case of DMA transfer), or Deep Sleep constraint (in case of regular wake up to process external data), rather than power down or a even lower low-power mode.

The 4 application compilation macros can be found in app_preinclude.h file of the project. See

app_preinclude.h for low power reference design peripheral application :

```
/*! Lowpower Constraint setting for various BLE states (Advertising, Scanning, connected mode)
   The value shall map with the type defintion PWR_LowpowerMode_t in PWR_Interface.h
     0 : no LowPower, WFI only
     1 : Reserved
     2 : Deep Sleep
     3 : Power Down
     4 : Deep Power Down
   Note that if a Ble State is configured to Power Down mode, please make sure
     gLowpowerPowerDownEnable_d variable is set to 1 in Linker Script
   The PowerDown mode will allow lowest power consumption but the wakeup time is longer
     and the first 16K in SRAM is reserved to ROM code (this section will be corrupted on
     each power down wakeup so only temporary data could be stored there.)
         Power down feature not supported. */

#define gAppLowPowerConstraintInAdvertising_c          3
/* Scanning not supported on peripheral */
//#define gAppLowPowerConstraintInScanning_c            2
#define gAppLowPowerConstraintInConnected_c           2
#define gAppLowPowerConstraintInNoBleActivity_c       4
```

In lowpower_central.c lowpower_preripheral.c files, the application sets and releases the low power constraint from BleApp_SetLowPowerModeConstraint() and BleApp_ReleaseLowPowerModeConstraint() functions. These functions are called with the macro value passed as argument.

> **Important Note :** Setting the application low power constraint shall be done on new Bluetooth LE state request so the new constraint is applied immediately, while the application low-power mode constraint shall be released when the Bluetooth LE state is exited. For example, setting the new low power constraint for Advertising shall be done when the application requests advertising to start. Releasing the low power constraint shall be done in the advertising stop callback (advertising has been stopped).

After releasing the low power constraint, the previous low power constraint, (likely the one that has been set during firmware initialization in APP_ServiceInitLowpower() function, or the updated low power constraint in BleApp_StartInit() function) applies again.

2.4.3 - Idle task implementation example

2.4.3.1 Tickless mode support and Low power entry function Idle task configuration from FreeRTOS shall be enabled by configUSE_TICKLESS_IDLE in FreeRTOSConfig.h. This will have the effect to have vPortSuppressTicksAndSleep() called from Idle task created by FreeRTOS. Here is a typical implementation of this function:

```
void vPortSuppressTicksAndSleep(TickType_t xExpectedIdleTime)
{

    bool abortIdle = false;
    uint64_t actualIdleTimeUs, expectedIdleTimeUs;

    /* The OSA_InterruptDisable() API will prevent us to wakeup so we use
     * OSA_DisableIRQGlobal() */
    OSA_DisableIRQGlobal();

    /* Disable and prepare systicks for low power */
    abortIdle = PWR_SysticksPreProcess((uint32_t)xExpectedIdleTime, &expectedIdleTimeUs);

    if (abortIdle == false)
    {
```

(continues on next page)

(continued from previous page)

```
        /* Enter low power with a maximal timeout */
        actualIdleTimeUs = PWR_EnterLowPower(expectedIdleTimeUs);

        /* Re enable systicks and compensate systick timebase */
        PWR_SysticksPostProcess(expectedIdleTimeUs, actualIdleTimeUs);
    }

    /* Exit from critical section */
    OSA_EnableIRQGlobal();
}
```

2.4.3.2 Connectivity background tasks and Idle hook function example Some process needs to be run in background before going into low power. This is the case for writing in NVM, or firmware update OTA to be writen in Flash. If so, configUSE_IDLE_HOOK shall be enabled in FreeRTOSCOnfig.h so vApplicationIdleHook() will be called prior to vPortSuppressTicksAndSleep(). Typical implementation of vApplicationIdleHook() function can be found here :

```
void vApplicationIdleHook(void)
{
    /* call some background tasks required by connectivity */
#if ((gAppUseNvm_d) || \
    (defined gAppOtaASyncFlashTransactions_c && (gAppOtaASyncFlashTransactions_c > 0)))

    if (PLATFORM_CheckNextBleConnectivityActivity() == true)
    {
        BluetoothLEHost_ProcessIdleTask();
    }
#endif
}
```

PLATFORM_CheckNextBleConnectivityActivity() function implemented in low power platform file fwk_platform_lowpower.c typically checks the next connectivity event and returns true if there's enough time to perform time consuming tasks such as flash erase/write operations (can be defined by the compile macro depending on the platform).

2. Low power features

2.1 - FreeRTOS systicks Low power module in framework supports the systick generation for FreeRTOS. Systicks in FreeRTOS are most of the time not required in the Bluetooth LE demos applications because the framework already supports timers by the timer manager component, so the application can use the timers from this module. The systicks in FreeRTOS are useful for all internal timer service provided by FreeRTOS (through OSA) like OSA_TimeDelay(), OSA_TimeGetMsec(), OSA_EventWait(). When systicks are enabled, an interrupt (systick interrupt) is triggered and executed on a periodic basis. In order to save power, periodic systick interrupts are undesirable and thus disabled when going to low-power mode. This feature is called low power FreeRTOS tickless mode. When entering the low power state, the system ticks shall be disabled and switch to a low power timer. On wake-up, the module retrieves the time passed in low power and compensate the ticks count accordingly. This feature does not apply on bare metal scheduler.

On FreeRTOS, the vPortSuppressTicksAndSleep() function implemented in the app_low_power.c file will be called when going to idle. FreeRTOS will give to this function the xExpectedIdleTime, time in tick periods before a task is due to be moved into the Ready state. This function will manage the systicks (disable/enable) through PWR_SysticksPreProcess() and PWR_SysticksPostProcess() calls. Then, when calling PWR_EnterLowPower(), a time out duration in micro seconds will be given and the function will set a timer before entering low power.

In addition, this function will return the low power period duration, used to compensate the ticks count.

In our example low power reference design peripheral application, an OSA_EventWait() has been added to demonstrate the tickless mode feature. You can adjust the timeout with the gAppTaskWaitTimeout_ms_c flag in the app_preinclude.h file, its value in our demo is 8000ms. So 8 seconds after stopping any activity we will wake up from low power. If the flag is not defined in the application its value will be osaWaitForever_c and there will be no OS wake up.

2.2 - Selective RAM bank retention To optimize the consumption in low power, the linker script specific function PLATFORM_GetDefaultRamBanksRetained() is implemented. This function obtains the RAM banks that need to be retained when the device goes in low power, in order to set them with PLATFORM_SetRamBanksRetained() function. The RAM banks that are not needed are set in power off state, when the device goes in low power mode.

The function PLATFORM_GetDefaultRamBanksRetained() is linker script specific. Hence, it cannot be adapted for a different application. If these functions are called from board_lp.c, it is possible to give to PLATFORM_SetRamBanksRetained() a different bank_mask adapted to your specific application.

In deep power down, this feature does not have any impact because in this power mode, all RAM banks are already powered off.

3 - Low power modes overview PWR module API provides the capability to set low power mode constraints from various components or from the application. These constraints are provided to the SDK power manager. Upper layer (all Application code, connectivity stacks, etc.) can call directly the SDK Power Manger if it requires more advanced tuning. The PWR API can be found in PWR_Interface.h.

> **Note :** 'Upper layer' signifies all layers, applications, components, or modules that are above the connectivity framework in the Software architecture.
>
> **Note :** Each power domain has its own Low Power mode capability. The Low Power modes described below are for the main domain and it is supposed that the wake up domain goes to the same Low Power mode. This is not always true as the wake up domain that contains some wake up peripheral can go a lower Low Power mode state than the main domain so the peripherals in the wake up domain can remain operational when the main domain is in Low Power mode (deep sleep or power down modes). In this case, the context of the Hardware peripheral located in the wake up domain does not need to be saved and restored as for the peripherals located in the main domain

3.1 Wait for Interrupt (WFI) Definition

In the Wait for Interrupt (WFI) state, the CPU core is powered on, but is in an idle mode with the clock turned OFF.

Wake up time and typical use case

The wakeup time from this Low Power mode is insignificant because the Fast clock from FRO is still running.

This Low Power mode is mainly used when there is an hardware activity while the Software runs the Idle task. This allows the code execution to be temporarily suspende, thus reducing a bit the power consumption of the device by switching off the processor clock. When an interrupt fires, the processor clock is instantaneously restored to process the Interrupt Service Routine (ISR).

Usage

In order to prevent the software from programming the device to go to a lower Low Power mode (such as Deep Sleep, Power Down mode or Deep Power Down mode), the component responsible for the hardware drivers shall call PWR_SetLowPowerModeConstraint(PWR_WFI) function. When the Hardware activity is completed, the component shall release the constraint by calling PWR_ReleaseLowPowerModeConstraint(PWR_WFI).

Alternatively, the component can call PWR_LowPowerEnterCritical() and then PWR_LowPowerExitCritical() functions.

For fine tuning of the Low Power mode allowing more power saving, the component can call directly the SDK power manager API with PM_SetConstraints() function using the appropriate Low Power mode and low power constraint. However, this is reserved for more advanced user that knows the device very well. It is not recommended to do so.

The PWR module has no external dependencies, so the low-power entry and exit callback functions must be defined by the user for each peripheral that has specific low power constraints It is consequently convenient to register to the component the low power callbacks structure that is used for entering and exit low power critical sections. In Bluetooth LE, you can take the example in the app_conn.c file as shown here :

```
#if defined(gAppLowpowerEnabled_d) && (gAppLowpowerEnabled_d>0)
static const Seclib_LowpowerCriticalCBs_t app_LowpowerCriticalCBs =
{
  .SeclibEnterLowpowerCriticalFunc = &PWR_LowPowerEnterCritical,
  .SeclibExitLowpowerCriticalFunc  = &PWR_LowPowerExitCritical,
};
#endif

void BluetoothLEHost_Init(..)
{
  ...
      /* Cryptographic hardware initialization */
      SecLib_Init();
#if defined(gAppLowpowerEnabled_d) && (gAppLowpowerEnabled_d>0)
      /* Register PWR functions into SecLib module in order to disable device lowpower
         during Seclib processing. Typically, allow only WFI instruction when
         commands (key generation, encryption) are processed by Seclib  */
      SecLib_SetLowpowerCriticalCb(&app_LowpowerCriticalCBs);
#endif
  ...
}
```

Limitations

No limitation when using the WFI mode.

3.2 Sleep mode Sleep mode is similar to WFI low power mode but with some additional clock gating. The Sleep mode is device specific, please consult the Hardware reference manuel of the device for more information.

3.2 Deep Sleep mode Definition

In Deep Sleep mode, the fast clock is turned off, and the CPU along with the main power domain are placed into a retention state, with the voltage being scaled down to support state retention only. Because no high frequency clock is running, the voltage applied on the power domain can be reduced to reduce leakage on the hardware logic. This reduces the overall power consumption in the Deep Sleep mode. When waking up from Deep sleep mode, the core voltage is increased back to nominal voltage and the fast clock (FRO) is turned back on, the peripheral in this domain can be reused as normal.

To same more additional power, Some unused RAM banks can be powered off. this prevents from having current leakage and consequently, allow to reduce even more the power consumption in Deep SLeep mode. This is achieved by calling PLATFORM_SetRamBanksRetained() from low power entry function from board_lp.c file.

Usage

All firmware is able to implement Deep Sleep mode transparently to the application thanks to the PWR module, low power platform submodule and low power board file. This is described in the section Low-power implementation.

When entering this mode, it is recommended to turn the output pins into input mode, or high impedance to reduce leakage on the pads. This is typically done in pin_mux.c file, called from board.c file and executed from the low power callback in board_lp.c file. As an example, the TX line of the UART peripheral can be turned to disabled so it prevents the current from being drawn by the pad in Low Power mode.

Wake up time and typical use case

The wake up time is very fast, it takes mostly the time for the Fast FRO to start up again (couple of hundreds of microseconds) so this mode is a very good balance between power consumption in low-power mode and wake up latency and shall be used extensively in most of the use cases of the application.

Limitations

In Deep Sleep mode, the clock is disabled to the CPU and the main peripheral domain, so peripheral activity (for example, an on-going DMA transfer) is not possible in Deep Sleep mode.

3.3 Power Down mode **Definition**

In Power Down mode, both the clock, and power are shut off to the CPU and the main peripheral domain. SRAM is retained, but register values are lost. The SDK power manager handles the restore of the processor registers and dependencies such as interrupt controller and similar ones transparently from the application.

Usage

The application, with the help of the low power board files, saves and restores the peripherals that were located in the power domain during the entry and exit of the power down mode. This is done from low power board_lp files in the entry/exit low power callbacks. Example is given for the serial manager and debug console in *board_lp.c* file in function *BOARD_ExitPowerDownCb()*.

If the device contains a dedicated wake up power domain where some wake up peripherals are located, if this wake up domain is not turned into power down mode but only Deep sleep mode or active mode, this peripheral does not need for a save and restore on low power entry/exit. For instance, on KW45, This is basically achieved when enabling the wakeup source of the peripheral *PWR_EnableWakeUpSource()* from *APP_ServiceInitLowpower()* function. Alternatively, this can be directly achieved by setting the constraint to the SDK power manager by calling *PM_SetConstraints()*, (use APP_LPUART0_WAKEUP_CONSTRAINTS for wakeup from UART constraint).

On exit from low power, The low power state of power domain can be retrieved by Platform API PLATFORM_GetLowpowerMode(). This API shall be called from low power exit callback function only.

As for Deep Sleep mode, software shall configure the output pins into input or high impedance during the Low Power mode to avoid leakage on the pads.

Wake up time and typical use case

The wake up time is significantly longer than wake up time from Deep Sleep (from several hundreds of micro-seconds to a couple of milliseconds depending on the platform). On some platform, it can takes longer, for instance, if ROM code is implemented and perform authentication checks for security and hardware logic in power domain needs to be restored (case for KW45).

However, After ROM code execution, the SDK power manager resumes the Idle task execution from where it left before entering low-power mode. Hence, the wakeup time from this mode is still significantly lower that the initialization time from a power on reset or any other reset.

Depending on the wakeup time of the platform and the low power time duration, This mode is recommended when no Software activity is expected to happen for the next several seconds. In Bluetooth LE, this mode is preferred in advertising or without Bluetooth LE activity. However, in scanning or connected mode, Regular wakes up happens regularly for instance to retrieve HCI message responses from the Link layer, the Deep Sleep mode is rather recommended.

Limitations

In addition to the Deep Sleep limitation (no Hardware processing on going when going to Power down mode) and the significant increase of the wake time, the Power Down mode requires the ROM code to execute and this last uses significant amount of memory in SRAM.

Typically, The first SRAM bank (16 KBytes) is used by the ROM code during execution so the Application firmware can use this section of SRAM for storing bss, rw data, or stacks. Only temporary data could be stored here and this location is overwritten on every Power Down exit sequence.

In order to avoid placing firmware data section (bss, rw, etc.) in the first SRAM bank, the linker script variable *gLowpowerPowerDownEnable_d* should be set to 1. Setting the linker script variable to avoid placing firmware data section in the first SRAM bank, The effect of setting this flag is to prevent the firmware from using the first 16 KB in SRAM.

> *Note* : This setting is ONLY required if the application implements Power Down mode.
> If Application uses other low-power mode, this is not required.

3.4 Deep Power-down mode **Definition**

In Deep Power Down mode, the SRAM is not retained. This power mode is the lowest disponible, it is exited through reset sequence.

Usage

In addition to the Power Down limitation, the Deep Power Down mode shut down all memory in SRAM. Because it is exited through reset sequence the wake time is also longer.

Wake up time and typical use case

As this low-power mode is exited through the reset sequence, the wake up time is longer than any other mode. In Bluetooth LE, this mode is possible in no Bluetooth LE activity, and is preferred if we know that there will be no Bluetooth LE activity before a several amount of time.

Limitations

All memory in SRAM will be shut down in deep power down, the main limitation in going in this low-power mode is that the context will not be saved.

ModuleInfo

Overview The ModuleInfo is a small Connectivity Framework module that provides a mechanism that allows stack components to register information about themselves.

The information comprises :

- Component or module name (for example: Bootloader, IEEE 802.15.4 MAC, and Bluetooth LE Host) and associated version string
- Component or module ID
- Version number
- Build number

The information can be retrieved using shell commands or FSCI commands.

Detailed data types and APIs used in ConnFWK_APIs_documentation.pdf.

NVM: Non-volatile memory module

Overview In a standard Harvard-architecture-based MCU, the flash memory is used to store the program code and program constant data. Modern processors have a built-in flash memory controller that can be used under user program execution to store non-volatile data. The flash memories have individually erasable segments (sectors) and each segment has a limited number of erase cycles. If the same segments are used to store various kinds of data all the time, those segments quickly become unreliable. Therefore, a wear-leveling mechanism is necessary to prolong the service life of the memory. The NVM module in the connectivity framework provides a file system with a wear-leveling mechanism, described in the subsequent sections. The *NvIdle()* function handles the program and erase memory operations. Before resetting the MCU, *NvShutdown()* must be called to ensure that all save operations have been processed.

NVM boundaries and linker script requirement Most of the MCUs have only a standard flash memory that the non-volatile (NV) storage system uses. The amount of memory that the NV system uses for permanent storage and its boundaries are defined in the linker configuration file though the following linker symbols :

- NV_STORAGE_START_ADDRESS
- NV_STORAGE_END_ADDRESS
- NV_STORAGE_MAX_SECTORS
- NV_STORAGE_SECTOR_SIZE

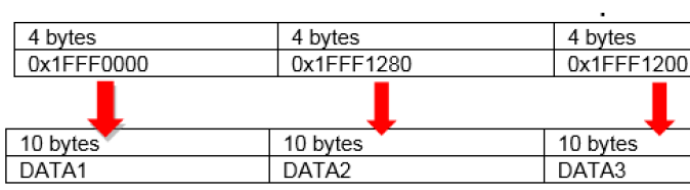
The reserved memory consists of two virtual pages. The virtual pages are equally sized and each page is using one or more physical flash sectors. Therefore, the smallest configuration is using two physical sectors, one sector per virtual page.

NVM Table The Flash Management and Non-Volatile Storage Module holds a pointer to a RAM table. The upper layers of this table register information about data that the storage system should save and restore. An example of NVM table entry list is given below.

pData	ElemCount	ElemSize	EntryId	EntryType
0x1FFF9000	3	8	0xF1F4	MirroredInRam
0x1FFF7640	5	4	0xA2A6	NotMirroredInRam
0x1FFF1502	6	1	0x4212	NotMirroredInRam AutoRestore
0x1FFFF200	2	6	0x118F	MirroredInRam

NVM Table entry As show above, A NVM table entry contains a generic pointer to a contiguous RAM data structure, the number of elements the structure contains, the size of a single element, a table entry ID, and an entry type.

A RAM table entry has the following structure:



- pData (4 bytes) is a pointer to the RAM memory location where the dataset elements are stored.

- elemCnt (2 bytes) represents how many elements the dataset has.
- elemSz (2 bytes) is the size of a single element.
- entryID is a 16-bit unique ID of the dataset.
- dataEntryType is a 16-bit value representing the type of entry (mirrored/unmirrored/unmirrored auto restore).

For mirrored datasets, pData must point directly to the RAM data. For unmirrored datasets, it must be a double pointer to a vector of pointers. Each pointer in this table points to a RAM/FLASH area. Mirrored datasets require the data to be permanently kept in RAM, while unmirrored datasets have dataset entries either in flash or in RAM. If the unmirrored entries must be restored at the initialization, NotMirroredInRamAutoRestore should be used. The entryID gUnmirroredFeatureSet_d should be set to 1 for enabling unmirrored entries in the application. The last entry in the RAM table must have the entryID set to gNvEndOfTableId_c.

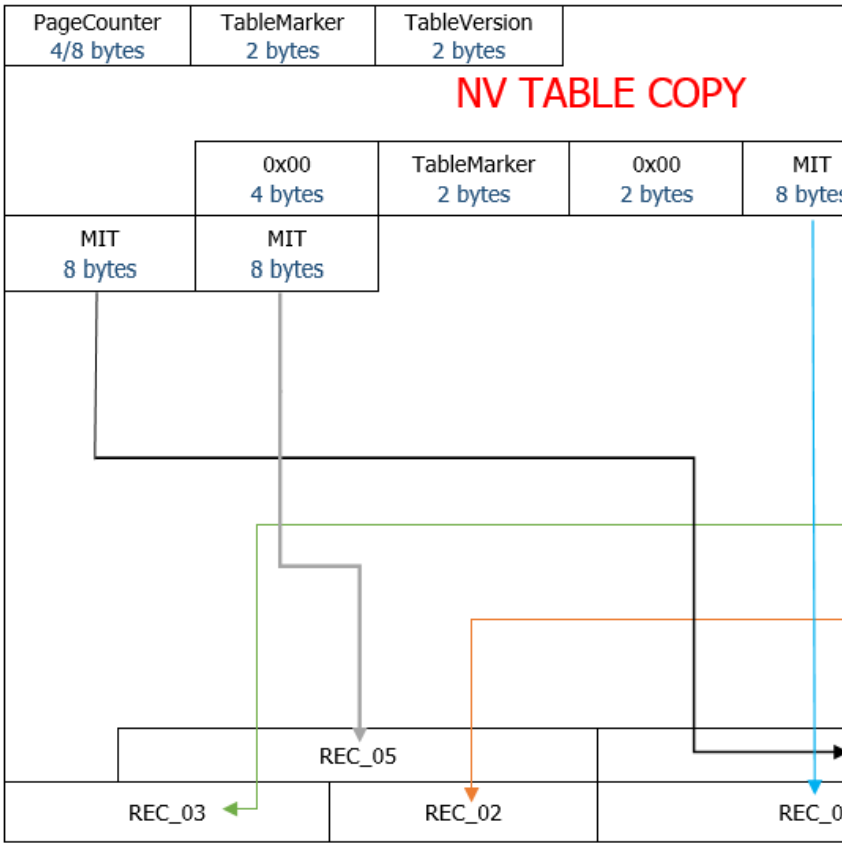
pData	0x1FFF8000
elemCnt	4
elemSz	10
entryID	1
dataEntryType	gNVM_NotM gNVM_NotM

The figure below provides an example of table entry :

When the data pointed to by the table entry pointer (pData) has changed (entirely or just a single element), the upper layers call the appropriate API function that requests the storage system to save the modified data. All the save operations (except for the synchronous save and atomic save) and the page erase and page copy operations are performed on system idle task. The application must create a task that calls NvIdle in an infinite loop. It should be created with OSA_PRIORITY_IDLE. However, the application may choose another priority. The save operations are done in one virtual page, which is the active page. After a save operation is performed on an unmirrored dataset, pData points to a flash location and the RAM pointer is freed. As a result, the effective data should always be allocated using the memory management module.

Active page The active page contains information about the records and the records. The storage system can save individual elements of a table entry or the entire table entry. Unmirrored datasets can only have individual saves. On mirrored datasets, the save/restore functions must receive the pointer to RAM data. For example, if the application must save the third element in the above vector, it should send 0x1FFF8000 + 2 * elemSz. For unmirrored datasets, the application must send the pointer that points to the area where the data is located. For example, if the application must save the third element in the above vector, it should send 0x1FFF8000 + 2 * sizeof(void*).

The page validity is guaranteed by the page counter. The page counter is a 32-bit value and is written at the beginning and at the end of the active page. The values need to be equal to consider the page a valid one. The value of the page counter is incremented after each page copy operation. A page erase operation is performed when the system is formatted. It is also performed when the page is full and a new record cannot be written into that page. Before being erased, the full page is first copied (only the most recent saves) and erased afterward.



The validity of the Meta Information Tag (MIT), and, therefore, of a record, is guaranteed by the MIT start and stop validation bytes. These two bytes must be equal to consider the record

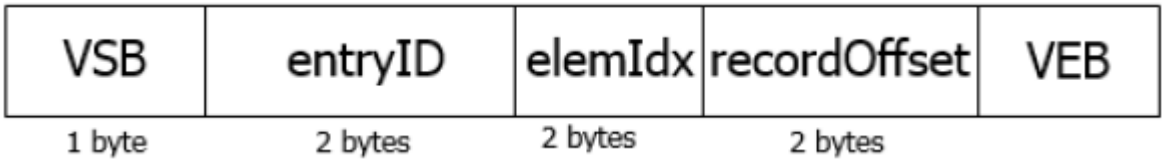
referred by the MIT valid. Furthermore, the value of these bytes indicates the type of the record, whether it is a single element or an entire table entry. The nonvolatile storage system allows dynamic changes of the table within the RAM memory, as follows:

- Remove table entry
- Register table entry

A new table entry can be successfully registered if there is at least one entry previously removed or if the NV table contains uninitialized table entries, declared explicitly to register new table entries at run time. A new table entry can also replace an existing one if the register table entry is called with an overwrite set to true. This functionality is disabled by default and must be enabled by the application by setting gNvUseExtendedFeatureSet_d to 1.

The layout of an active page is shown below:

As shown above, the table stored in the RAM memory is copied into the flash active page, just after the table version. The “table start” and “table end” are marked by the table markers. The data pointers from RAM are not copied. A flash copy of a RAM table entry has the following structure:



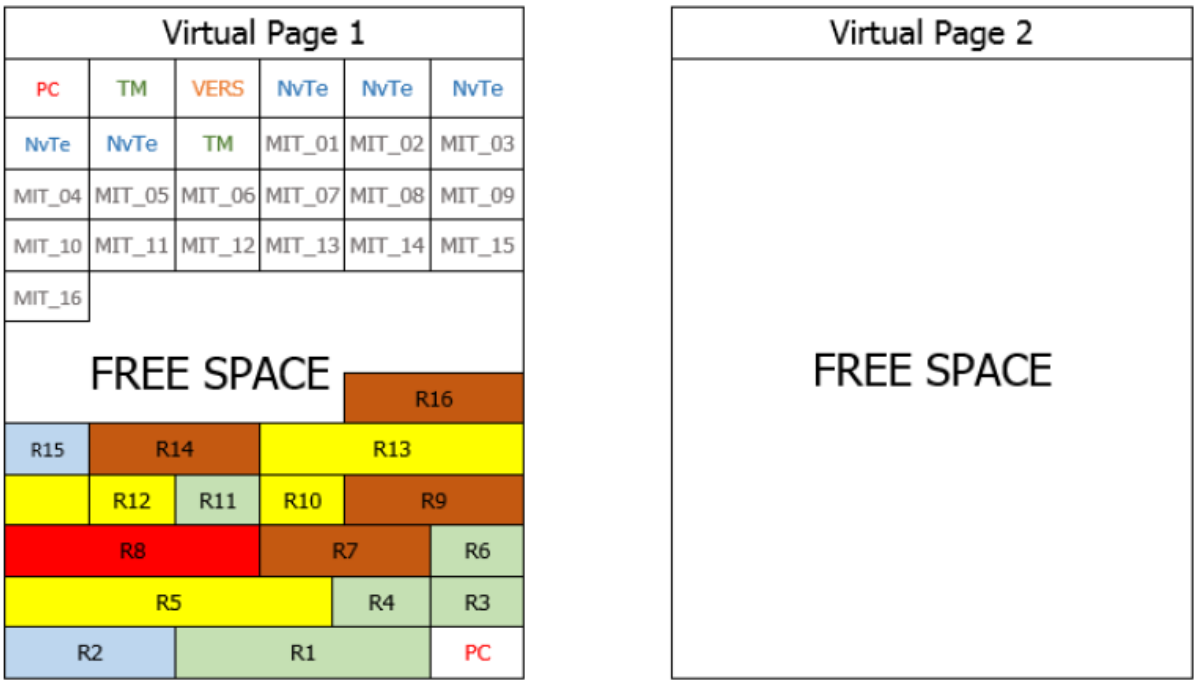
Where:

- entryID is the ID of the table entry
- entryType represents the type of the entry (mirrored/unmirrored/unmirrored auto restore)
- elemCnt is the elements count of that entry
- elemSz is the size of a single element

This copy of the RAM table in flash is used to determine whether the RAM table has changed. The table marker has a value of 0x4254 (“TB” if read as ASCII codes) and marks the beginning

and end of the NV table copy.

After the end of the RAM table copy, the Meta Information Tags (MITs) follow. Each MIT is used to store information related to one record. An MIT has the following structure:

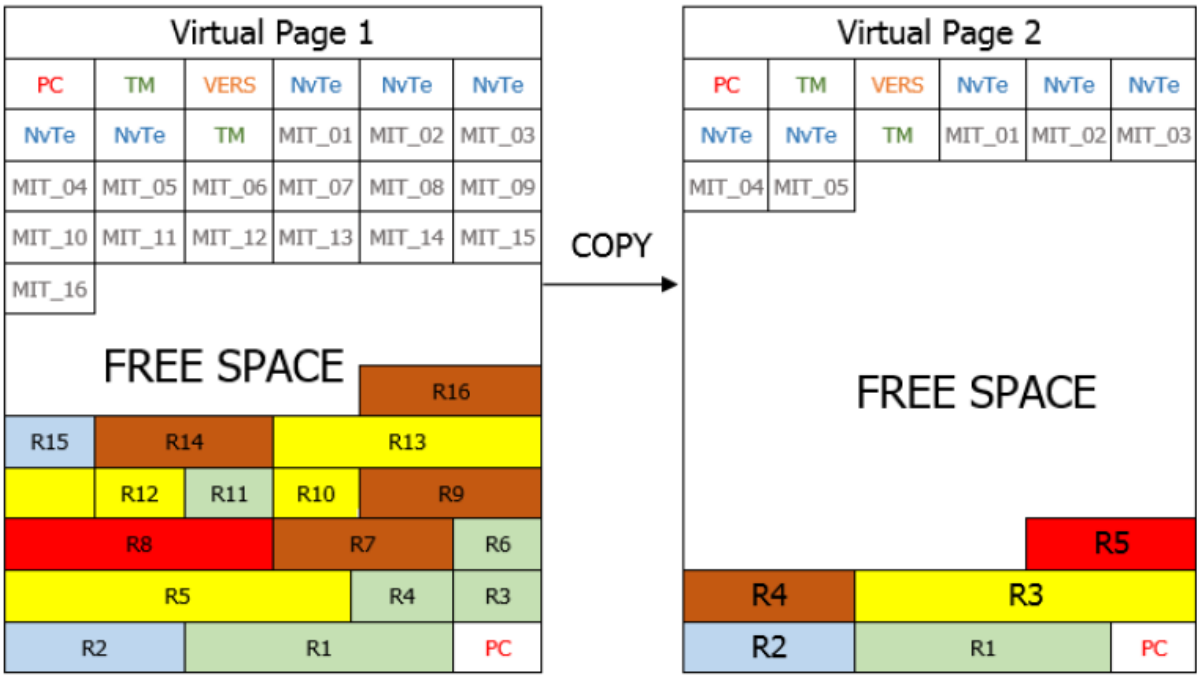


Where:

- VSB is the validation start byte.
- entryID is the ID of the NV table entry.
- elemIdx is the element index.
- recordOffset is the offset of the record related to the start address of the virtual page.
- VEB is the validation end byte.

A valid MIT has a VSB equal to a VEB. If the MIT refers to a single-element record type, VSB=VEB=0xAA. If the MIT refers to a full table entry record type (all elements from a table entry), VSB=VEB=0x55. Because the records are written to the flash page, the available page space decreases. As a result, the page becomes full and a new record does not have enough free space to be copied into that page.

In the example given below, the virtual page 1 is considered to be full if a new save request is pending and the page free space is not sufficient to copy the new record and the additional MIT. In this case, the latest saved datasets (table entries) are copied to virtual page 2.



In this example, there are five datasets (one color for each dataset) with both 'full' and 'single' record types.

- R1 is a 'full' record type (contains all the NV table entry elements), whereas R3, R4, R6 and R11 are 'single' record types.
- R2 – full record type; R15 – single record type
- R5, R13 – full record type; R10, R12 – single record type

- R8 – full record type
- R7, R9, R14, R16 – full record type

As shown above, the R3, R4, R6, and R11 are 'single' record types, while R1 is a 'full' record type of the same dataset. When copied to virtual page 2, a defragmentation process takes place. As a result, the record copied to virtual page 2 has as much elements as R1, but individual elements are taken from R3, R4, R6, and R11. After the copy process completes, the virtual page 2 has five 'full' record types, one for each dataset. |This is illustrated below:

Finally, the virtual page 2 is validated by writing the PC value and a request to erase virtual page 1 is performed. The page is erased on an idle task, sector by sector where only one sector is erased at a time when idle task is executed.

If there is any difference between the RAM and flash tables, the application must call RecoverNvEntry for each entry that is different from its RAM copy to recover the entry data (ID, Type, ElemSz, ElemCnt) from flash before calling NvInit. The application must allocate the pData and change the RAM entry. It can choose to ignore the flash entry if the entry is not desired. If any entry from RAM differs from its flash equivalent at initialization, a page copy is triggered that ignores the entries that are different. In other words, data stored in those entries is lost.

The application can check if the RAM table was updated. In other words, if the MCU program was changed and the RAM table was updated, using the function GetFlashTableVersion and compare the result with the constant gNvFlashTableVersion_c. If the versions are different, NvInit detects the update and automatically upgrades the flash table. The upgrade process triggers a page copy that moves the flash data from the active page to the other one. It keeps the entries that were not modified intact and it moves the entries that had their elements count changed as follows:

- If the RAM element count is smaller than the flash element count, the upgrade only copies as many elements as are in RAM.
- If the RAM element count is larger than the flash element count, the upgrade copies all data from flash and fills the remaining space with data from RAM. If the entry size is changed, the entry is not copied. Any entryIds that are present in flash and not present in RAM are also not copied. This functionality is not supported if gNvUseExtendedFeatureSet_d is not set to 1.

ECC Fault detection The KW45/K32W1 internal flash is organized in 16 byte phrases and 8kB sectors (minimal erase unit). Its flash controller is synthesized so that it generates ECC information and an ECC generator / checker. During the programming of internal flash, errors may accidentally happen and cause ECC errors as a flash phrase is being written. These may happen due to multiple reasons:

- programmatic errors such as overwriting an already programmed phrase (transitioning bits from 0b to 1b). These are evitable by performing a blank check verification over phrase to be programmed, at the expense of processing power.
- occurrence of power drop or glitches during a programming operation.
- excessive wear of flash sector. The flash controller is capable of correcting one single ECC error but raises a bud fault whenever reading a phrase containing more than one ECC fault. Once an ECC error has 'infected' a flash phrase, the fault will remain and raise again at each read operation over the same phrase including blank check and prefetch. It can only be rid of by erasing the whole flash sector that contained the faulty phrase. In order to recover from situations where an ECC fault has occurred a gNvSalvageFromEccFault_d option has been added, which forces gNvVerifyReadBackAfterProgram_d to be defined to TRUE. If defined, the gNvVerifyReadBackAfterProgram_d option of the NVM module, causes the program to read back the programmed area after every flash programming operation. The verification is performed in safe mode if gNvSalvageFromEccFault_d is also defined. This is so as to detect ECC faults as early as possible as they appear, indeed when verifying a programming operation, one cannot be certain of the absence of ECC fault and avoid the bus fault. The safe API is thence used to perform the read back operation is performed using this safe API, so that we can tread in the flash and detect potential errors. The defects are detected on the fly whereas in the absence of safe read back, the error would cause a fault, potentially much later. During normal operation, assuming that no chip reset was provoked, this will consist in a single ECC fault either in the last record data or its meta information. Detecting such a fault calls for an immediate page copy to the other virtual page, so that the currently active page gets erased and the error gets cleared. Should the ECC fault occurs in the middle of a page copy operation, the switch of active page is postponed so that the fault page can be erased again and the copy can be restarted.

If the system underwent a power drop during a flash programming operation, sufficient to provoke a reset, at the ensuing reboot, ECC fault(s) may be present in the NVM area at the location that was being written. The detection is performed by an NVM sweeping mechanism, using the safe read API. That marks the faulty virtual page so that all subsequent reads within this virtual page are done with the safe API. If this case arises, a copy of the valid contents of the faulty page is attempted to the other virtual page. At NVM initialization, faults should be detected, either at the top of the meta data or at the bottom of the record area within the previous active page. This should guarantee that only the latest record write operation may be impaired. When the page copy has taken place, the faulty page is erased and the execution may resume. During NvCopyPage, when 'garbage collecting' occurs or whenever the current virtual active page needs to be transferred to the other virtual page, ECC errors are intercepted so that the operation can be attempted again in case of error. In case of NVM contents clobbering by programming errors, the salvage operation does its best to rescue as many records as possible but data will inevitably be lost.

An additional option -namely *gInterceptEccBusFaults_d* - was introduced in order to catch and correct ECC faults at Bus Fault handler level. Indeed, should an ECC bus fault fire, in spite of the precautions taken with NVM's gNvSalvageFromEccFault_d, we verify if the fault belongs to the NV storage. If so, a drastic policy can be adopted consisting in an erasure of the faulty sector. The corresponding Bus Fault handling is not part of the NVM, but dwells in the framework platform specific sources. Alternative handling could be implemented by the customer.

Save policy: Execution of program and erase operations on a flash an MCU core fetches code from cause perturbations of the core activity or requires to place critical code in RAM so that real-time ISR can still be served. The penalty of a sector erase is much higher than a simple program operation. The NVM is designed so as to limit the erase operations at 'garbage collecting' time,

so that flash wear is limited and no time is wasted. Several write policies are implemented to cope with the application constraints, one synchronous mode API and several posted write APIs. Among the posted write policies, the gNvmSaveOnIdleTimerPolicy_d compilation option selects a mode where flash write operations occur at time interval within the Idle task. Another option exists to 'randomize' the time interval with some jitter.

1) NvSyncSave performs a write synchronously with the disadvantage of stalling processor activity until comp
2) NvSaveOnCount posts a pending write operation and postpones the actual flash operation until number of record updates has reached a maximum. The actual write happens during Idle Task execution.see NvSetCountsBetweenSaves related API.
3) NvSaveOnInterval: posts a pending write operation and postpones the actual flash operation until the predefined number of ticks has elapsed. Optional mode - Active if (gNvmSaveOnIdleTimerPolicy_d & gNvmUseSaveOnTimerOn_c). see NvSetMinimumTicksBetweenSaves related API. Note that gNvmUseSaveIntervalJitter_c policy is a sub-option of gNvmSaveOnIdleTimerPolicy_d used to randomize slightly the time at which the write operation will happen.

Constant macro definition

- *gNvStorageIncluded_d* : If set to TRUE, it enables the whole functionality of the nonvolatile storage system. By default, it is set to FALSE (no code or data is generated for this module).
- *gNvUseFlexNVM_d* : If set to TRUE, it enables the FlexNVM functionality of the nonvolatile storage system. By default, it is set to FALSE. If FlexNVM is used, the standard nonvolatile storage system is disabled.
- *gNvFragmentation_Enabled_d* : Macro used to enable/disable the fragmented saves/restores (a particular element from a table entry can be saved or restored). It is set to FALSE by default.
- *gNvUseExtendedFeatureSet_d* : Macro used to enable/disable the extended feature set of the module:
  - Remove existing NV table entries
  - Register new NV table entries
  - Table upgrade

  It is set to FALSE by default.
- *gUnmirroredFeatureSet_d* : Macro used to enable unmirrored datasets. It is set to 0 by default.
- *gNvTableEntriesCountMax_c* : This constant defines the maximum count of the table entries (datasets) that the application is going to use. It is set to 32 by default.
- *gNvRecordsCopiedBufferSize_c* : This constant defines the size of the buffer used by the page copy function, when the copy operation performs defragmentation. The chosen value must be bigger than the maximum number of elements stored in any of the table entries. It is set by default to 64.
- *gNvCacheBufferSize_c* : This constant defines the size of the cache buffer used by the page copy function, when the copy operation does not perform defragmentation. The chosen value must be a multiple of 8. It is set by default to 64.
- *gNvMinimumTicksBetweenSaves_c* : This constant defines the minimum timer ticks between dataset saves (in seconds). It is set to 4 by default.
- *gNvCountsBetweenSaves_c* : This constant defines the number of calls to 'NvSaveOnCount' between dataset saves. It is set to 256 by default.

- *gNvInvalidDataEntry_c* : Macro used to mark a table entry as invalid in the NV table. The default value is 0xFFFFU.
- *gNvFormatRetryCount_c* : Macro used to define the maximum retries count value for the format operation. It is set to 3 by default.
- *gNvPendingSavesQueueSize_c* : Macro used to define the size of the pending saves queue. It is set to 32 by default.
- *gFifoOverwriteEnabled_c* : Macro used to enable overwriting older entries in the pending saves queue (if it is full). If it is FALSE and the queue is full, the module tries to process the oldest save in the queue to free a position. It is set to FALSE by default.
- *gNvMinimumFreeBytesCountStart_c* : Macro used to define the minimum free space at initialization. If the free space is smaller than this value, a page copy is triggered. It is set by default to 128.
- *gNvEndOfTableId_c* : Macro used to define the ID of the end-of-table entry. It is set to 0xFFFEU by default. No valid entry should use this ID.
- *gNvTableMarker_c* : Macro used to define the table marker value. The table marker is used to indicate the start and the end of the flash copy of the NV table. It is set to 0x4254U by default.
- *gNvFlashTableVersion_c* : Macro used to define the flash table version. It is used to determine if the NVM table was updated. It is set to 1 by default. The application should modify this every time the NVM table is updated and the data from NVM is still required.
- *gNvTableKeptInRam_d* : Set gNvTableKeptInRam_d to FALSE, if the NVM table is stored in FLASH memory (default). If the NVM table is stored in RAM memory, set the macro to TRUE.
- *gNvVerifyReadBackAfterProgram_d* : set by default force verification of NVM programming operations. Is forced implicitly when gNvSalvageFromEccFault_d is defined.
- *gNvSalvageFromEccFault_d* : use safe flash API to read from flash, and provide corrective action when ECC fault is met.

OtaSupport: Over-the-Air Programming Support

Overview This module includes APIs for the over-the-air image upgrade process. A Server device receives an image over the serial interface from a PC or other device thorough FSCI commands. If the Server has an image storage, the image is saved locally. If not, the image is requested chunk by chunk: With image storage

- OTA_RegisterToFsci()
- OTA_InitExternalMemory()
- OTA_WriteExternalMemory()
- ...
- OTA_WriteExternalMemory()

Without image storage:

- OTA_RegisterToFsci()
- OTA_QueryImageReq()
- OTA_ImageChunkReq()
- ...
- OTA_ImageChunkReq()

A Client device processes the received image by computing the CRC and filter unused data and stores the received image into a non-volatile storage. After the entire image has been transferred and verified, the Client device informs the Bootloader application that a new image is available, and that the MCU must be reset to start the upgrade process. See the following command sequence:

- OTA_StartImage()
- OTA_PushImageChunk() and OTA_CrcCompute ()
- ...
- OTA_PushImageChunk() and OTA_CrcCompute ()
- OTA_CommitImage()
- OTA_SetNewImageFlag()
- ResetMCU()

SecLib_RNG: Security library and random number generator

Random number generator

Overview The RNG module is part of the framework used for random number generation. It uses hardware RNG peripherals as entropy sources (TRNG, Secure Subsystem, ...) to provide a true random number generator interface. A Pseudo-Random number generator (PRNG) implementation is available. The PRNG may depend of SecLib services (thus requiring a common mutex) to perform HMAC-SHA256, SHA256, AES-CTR, or alternateively a Lehmer Linear Congruential generator. A prerequisite for the PRNG to function with desired randomness is to be seeded using a proper source of entropy. If no hardware acceleration is present, the RNG may fallback to lesser quality ad-hoc source e.g if present SIM_UID registers, the UIDL is used as the initial seed for the random number generator.

Initialization The RNG module requires an initialization via a call to RNG_Init. The RNG initialization involves a call to RNG_SetSeed.

In the case of a dual core system consisting of a Host core and an NBU core, the Secure Subsystem is owned by the Host core. The Host core then has a direct access to its TRNG embedded in its secure subssystem. On the NBU code side, a request is emitted via RPMSG to the Host to provide a seed. On receipt of this request, the Host sets a 'reseed needed' flag (from the ISR context) If the core running the RNG service owns the TRNG entropy hardware (if any), it can get the seed directly form this hardware synchronously. In the case of an NBU that does not control the devices entropy source, that is owned by the Host, it request a seed from the Host processor via RPMSG exchange. On receipt of this request the Host sets a flag notifying of this request from the RPMSG ISR context. From the Idle thread, this flag is polled via the RNG_IsReseedNeeded API. If set the seed is regenerated and forwarded to the NBU via RPMSG.

RNG_ReInit API is to be used at wake up time in the context of LowPower. RNG_DeInit is used for unit tests and coverage purposes but has no useful role in a real application.

Seed handling RNG_SetSeed: RNG_SetExternalSeed may be used to inject application entropy to RNG context seed using a supplied array of bytes. RNG_IsReseedNeeded used from task in Host core to check whether seed must be sent to NBU core.

RNG_GetTrueRandomNumber is the API used to generate a Random 32 bit number from a HW source of entropy. It is essential if only to seed the pseudo random number generator.

RNG_GetPseudoRandomData is used to generate arrays of random bytes.

Security Library

Overview The framework provides support for cryptography in the security module. It supports both software and hardware encryption. Depending on the device, the hardware encryption uses either the S200, MMCAU, LTC, or CAU3 module instruction set or dedicated AES and SHA hardware blocks.

Software implementation is provided in a library format.

Support for security algorithms

	SW Seclib : SecLib.c	EdgeLock SecLib_sss.c	Seclib_e	Mbedtls SecLib_mbec	nccl (part of SecLib.c)	Usage example
AES_128	SecLib_aes.c	x		x		
AES_128_ECB		x		x		
AES_128_CBC	x	x		x		
AES_128_CTR encryption	x	x				
AES_128_OFB Encryption	x

SPAKE2+ P256 arithmetics				x	x	Matter

BLE advanced secure mode

New elements in existing structures: computeDhKeyParam_t::keepInternalBlob - boolean telling if the shared blob is kept in this structure(in .outpoint) after ECDH_P256_ComputeDhKey() or ECDH_P256_ComputeDhKeySeg() call.

New arguments in existing functions: ECDH_P256_ComputeDhKey keepBlobDhKey - boolean telling ECDH_P256_ComputeDhKey() or ECDH_P256_ComputeDhKeySeg() to keep the shared object after computation for later use (it is required by the SecLib_GenerateBluetoothF5KeysSecure).

New macros: gSecLibSssUseEncryptedKeys_d - Enable or disable S200 blobs SecLib support. 0 - the Bluetooth Keys are available in plaintext, 1 - the Bluetooth Keys are not available in plaintext, but in secured blobs. Default is disabled.

New functions:

LE Secure connections pairing:

void ECDH_P256_FreeDhKeyDataSecure This is a function used to free the shared object stored in computeDhKeyParam_t. When user calls ECDH_P256_ComputeDhKeySeg() with keepBlobDhKey set to 1, it should also call **ECDH_P256_FreeDhKeyDataSecure** .

SecLib_GenerateBluetoothF5Keys This function is extracted from the Bluetooth LE Host Stack implementation. This corresponds to the legacy implementation without key blobs.

SecLib_GenerateBluetoothF5KeysSecure Similar to **SecLib_GenerateBluetoothF5Keys** this function is modified to work with key blobs, the reason is to not use SSS inside the Bluetooth LE Host Stack.

SecLib_DeriveBluetoothSKD This is a helper function used by the Bluetooth LE Host Stack in the pairing procedure, when receiving the vendor HCI command specifying that the ESK needs to be provided to LL.

ELKE_BLE_SM_F5_DeriveKeys This is a private function, helper for **SecLib_GenerateBluetoothF5KeysSecure**. It was provided by the STEC team.

Privacy:

SecLib_ObfuscateKeySecure This is a function used by the Bluetooth LE Host Stack to obfuscate the IRK before setting it to Bluetooth LE Controller or before saving it to NVM

SecLib_DeobfuscateKeySecure This is a function used by the Bluetooth LE Host Stack to extract the plaintext IRK key from the saved NVM blob.

SecLib_VerifyBluetoothAh This function is extracted from the legacy Bluetooth LE Host Stack implementation using plaintext keys.

SecLib_VerifyBluetoothAhSecure Similar to **SecLib_VerifyBluetoothAh** with modification to work with S200 key blob.

SecLib_GenerateSymmetricKey This is a function used by the application to generate the local IRK and local CSRK.

SecLib_GenerateBluetoothEIRKBlobSecure This is a function used by the application to generate the EIRK needed by Bluetooth LE Controller from the IRK blob.

A2B feature

ECDH_P256_ComputeA2BKey This function is used to compute the EdgeLock to EdgeLock key. pInPeerPublicKey points to the peer public key, pOutE2EKey is the pointer to where the E2E key object will be stored, this will be freed by the application when it is no longer required by calling ECDH_P256_FreeE2EKeyData().

ECDH_P256_FreeE2EKeyData This function is used to free the key object given as a parameter. It is used by the application to free the E2E key when is no longer needed.

SecLib_ExportA2BBlobSecure This function is used to import an ELKE blob or plain text symmetric key in s200 and export an E2E key blob. The input type is identified by the keyType parameter.

SecLib_ImportA2BBlobSecure This function is used to import an E2E key blob in s200 and export an ELKE blob or plain text symmetric key. The output type is identified by the keyType parameter.

LE Secure connections Pairing flow and SecLib usage:

1. Each device needs to generate locally the public+private keypair. This is done using **ECDH_P256_GenerateKeys**.
2. Devices exchange their public keys.
3. Upon receiving the peer device's public key, local device is computing DH key using **ECDH_P256_ComputeDhKey**.
4. Each device sends DHKeyCheck packet
5. Upon receiving DhKeyCheck each device computes LTK blob using **SecLib_GenerateBluetoothF5Keys**
6. After computing the each device sends HCI_LeStartEnc (on initiator), HCI_Le_Provide_Long_Term_Key (on responder)
7. Bluetooth LE Controller sends back SKD report custom event
8. Bluetooth LE Host Stack computes ESKD based on LTK blob using **SecLib_DeriveBluetoothSKD** and sends it to Bluetooth LE Controller
9. Bluetooth LE Controller encrypts the link

IRK flow and SecLib usage:

1. At startup, when gInitializationComplete_c event is received:
   - the local IRK is generated using **SecLib_GenerateSymmetricKey**
   - the local EIRK is generated using **SecLib_GenerateBluetoothEIRKBlobSecure**
   - local CSRK is generated using **SecLib_GenerateSymmetricKey**
2. During legacy pairing when receiving bonding keys, IRK is obfuscated using **SecLib_ObfuscateKeySecure** and stored
3. When app wants to set the OOB keys using Gap_SaveKeys the IRK is obfuscated using **SecLib_ObfuscateKeySecure**
4. When application calls API Gap_VerifyPrivateResolvableAddress IRK is obfuscated using **SecLib_ObfuscateKeySecure** and verified using **SecLib_VerifyBluetoothAhSecure**
5. When a new connection is received in Host with RPA address not resolved by the Bluetooth LE Controller, the Host tries to resolve it by obfuscating it using **SecLib_ObfuscateKeySecure** and verifying it using **SecLib_VerifyBluetoothAhSecure**
6. When adding a peer in Bluetooth LE Controller resolving list, the peer's IRK is obfuscated using **SecLib_ObfuscateKeySecure** before setting it using **HCI_Le_Add_Device_To_Resolving_List**.
7. When an IRK plaintext is requested by the application using Gap_LoadKeys it is obtained using **SecLib_DeobfuscateKeySecure**
8. When legacy pairing completes and LTK needs to be send in the pairing complete event (gConnEvtPairingComplete_c) the **SecLib_DeobfuscateKey** is used to extract the plaintext.

A2B flow and SecLib usage:

1. At startup, when gInitializationComplete_c event is received, the application will call **ECDH_P256_GenerateKeys** to generate the public/private key pair required for the E2E key derivation and send the public key to the peer device.
2. When the public key is received from the peer device, the application will call **ECDH_P256_ComputeA2BKeySecure** to generate the EdgeLock to EdgeLock key.
3. The application will obtain an E2E IRK blob by calling **SecLib_ExportA2BBlobSecure** with key type gSecElkeBlob_c. The obtained blob is sent to the peer anchor. The peer anchor will call **SecLib_ImportA2BBlob** with keyType gSecElkeBlob_c and save the resulting ELKE blob in NVM, for Digital Key both anchors must have the same IRK.
4. After pairing, in order to send the LTK and IRK contained in the bonding data securely, the application will call **SecLib_ExportA2BBlobSecure** with keyType gSecLtkElkeBlob_c for the LTK, and **SecLib_ExportA2BBlobSecure** with keyType gSecPlainText_c for the IRK. The E2E blobs obtained are sent along with the rest of the bonding data to the peer anchor device.
5. After the bonding data is trasfered the E2E key is no longer needed and **ECDH_P256_FreeE2EKeyData** is called with the key object obtained at step 2 when **ECDH_P256_ComputeA2BKeySecure** was called.

Sensors

Overview The Sensors module provides an API to communicate with the ADC. Two values can be obtained by this module :

- Temperature value

- Battery level

The temperature is given in tenths of degrees Celsius and the battery in percentage.

This module is multi-caller, the ADC is protected by a mutex on the resource and by prevententing lowpower (only WFI) during its processing. Platform specific code can be find in fwk_platform_sensors.c/h.

Constant macro definitions Name :

```
#define VALUE_NOT_AVAILABLE_8 0xFFu
#define VALUE_NOT_AVAILABLE_32 0xFFFFFFFFu
```

Description :

Defines the error value that can be compared to the value obtain on the ADC.

SFC : Smart Frequency Calibration

Overview The Smart Frequency Calibration module provides operations and calibration for the FRO32K source clock. This module is split between main core and Radio core:

- fwk_rf_sfc.[ch]: RF_SFC module on Radio core that provides Main FRO32K measurement/calibration and state machine in synchornization with Radio domain activities. See details below.
- fwk_sfc.h: SFC module on host core that provides type definition for usage with fwk_platform_ics.[ch] with PLATFORM_FwkSrvSetRfSfcConfig() API and fwk_platform_ble.c for received callback from the NBU core

Host SFC Module

Algorithm parametrization This module provides ability to configure the RF_SFC module by sending message to Radio core through fwk_platform_ics.c PLATFORM_FwkSrvSetRfSfcConfig():

- Filter size
- Maximum ppm threshold
- Maximum calibration interval
- Number of sample in filter to swicth from convergence to monitor mode

Ppm target The ppm target is the deviation from the target clock accepted by the algorithm. When the deviation is larger than the ppm target. The algorithm will update the trimming value and reset the filter. The ppm target cannot be more aggressive RF_SFC_MAXIMAL_PPM_TARGET in order to avoid having to update trimming value at each measurement.

Filter size Filter size must be included between RF_SFC_MINIMAL_FILTER_SIZE and RF_SFC_MAXIMAL_FILTER_SIZE. See *Filtering and Frequency estimation* section for more details on the parameter.

Maximum calibration interval In monitor mode, new measurement are triggered by low-power entry/exit. If the NBU core has a lot of radio activity it could never enter lowpower. The maximum calibration interval is here to ensure a measurement is done regularly. When executing idle the SFC module checks when the last measurement has been done, if it has been too long, it reset the filter and forces a new measurement

Trig sample number The trig sample number is the number of samples needed by the algorithm in its filter to switch from convergence to monitor mode. Having more than one sample in convergence mode allows to confirm the trimming value that we have set.

SFC debug information On the other way, the RF_SFC from Radio core sends back notifications to SFC module on main core using RX callback PLATFORM_RegisterFroNotificationCallback() from fwk_platform_ics.h and such information:

- last measured frequency
- average ppm from 32768Khz frequency
- last ppm measured from 32768Khz frequency
- FRO trimming value

RF_SFC module The RF_SFC module provides the functionality to calibrate the FRO32K source clock during Initialization and radio activity.

The RF_SFC is mostly used on XTAL32K less solution when no 32Khz crystal is soldered on the board. It allows to calibrate the FRO32K source clock to the desired frequency to keep Radio time base within the allowed tolerance given by the connectivity standards. However, even on a XTAL32K solution, the RF_SFC is also used during Initialization until the XTAL32K is up and running in the system. The system firstly runs on the FRO32K clock source then switch to the XTAL32K clock source when it is ready with enough accuracy. This allows to save significant boot time as the FRO32K start up (including calibration) is much faster compared to XTAL32K .

This module will handle:

- FRO32K clock frequency measurement against 32Mhz crystal. It schedules appropriately the start of the measurement and gets the result when completed,
- Filter and estimate the 32Khz frequency value and error by averaging from the last measurements,
- FRO32K calibration in order to update the trimming value to reduce the frequency error on the clock.

The targeted frequency offset shall be within 200ppm. The RF_SFC will handle two modes of operation:

- Convergence mode: when frequency estimation is above 200pm,
- Monitor mode: when frequency estimation is below 200pm.

The RF_SFC module works in active and all low power modes on NBU domain, or on host application domain except power down mode. Power down mode on host application domain is not supported with the FRO32K configuration as clock source.

Feature enablement Enabling the FRO32K is done by calling the PLATFORM_InitFro32K() function during application initialization in hardware_init.c file, in BOARD_InitHardware() function. If FRO32K is not enabled, Oscillator XTAL32K shall be called instead by calling PLATFORM_InitOsc32K() function. The call to PLATFORM_InitFro32K() from BOARD_InitHardware() can be done by setting the Compilation flag gBoardUseFro32k_d to 1 in hardware_init.c or any header files included from this file.

```
#define gBoardUseFro32k_d       1
```

Detailed description

Frequency measurements When NBU low power is enabled, the frequency measurements are triggered on Low power wake-up by HW signal. The SFC process called from Idle task will check regularly the completion of the frequency measurement. When the measurement is done, it goes to filtering and frequency estimation process. The frequency measurement duration depends on monitor mode or convergence mode: In convergence mode, the frequency measurement duration is 0.5ms while it is 2ms in monitor mode. In monitor mode, the duration value remains less than the minimal radio activity duration so it does not impact the low power consumption in monitoring mode.

Filtering and Frequency estimation The FRO32KHz frequency measurement values are noisy because of thermal noise on the FRO32K itself. Also, the frequency measurement can introduce some error. In monitoring mode, it is required to filter the measurements by applying an exponential filter. new_estimation = (new_measurement + ((1 « n) -1) * last_estimation) » n

Default value for n is 7 (meaning 128 samples in the averaging window).

Frequency calibration When the frequency estimation gets higher than the targeted 200ppm target, the RF_SFC updates the trimming value for one positive or negative increment. For this purpose, it requires to:

- wake up the host application domain and keep the domain active,
- update the trim register of the FRO32K , this register is used to trim the capacitance value of the FRO32K,
- re-allow the host application domain to enter low power.

A slight power impact is expected during a calibration update due to host domain wake-up.

Operational modes When the low power mode is enabled on NBU power domain, RF SFC handles two modes of operation: convergence and monitor modes. However, when low power is disabled on NBU power domain, only convergence mode is supported.

Convergence mode Convergence mode is used when the estimated FRO32K frequency is above 200ppm or when the filter has been reset. Typically this occurs :

- During Power ON reset or other reset when NBU is switched OFF
- When temperature varies and FRO32K frequency deviates outside 200ppm threshold target
- When no calibration has been done during some time as we discard old values that could influence the algorithm

The convergence mode process typically starts with a FRO32K trim register update, performs a frequency measurement and the FRO32K trim register is updated until the measured frequency gets below 200ppm. These operations are repeated in a loop until the estimated frequency value gets below 200ppm. When below 200ppm during multiple measurements, the RC SFC switches to Monitoring mode. The convergence mode is only a transition mode to monitoring mode. In convergence mode, the NBU power domain does not go to low power. The convergence mode time duration depends on the initial frequency error of the FR032K. Default frequency measurement duration is 0.5ms so 20 measurements (given as example only) will require less than 10 ms to converge.

Monitoring mode Monitoring mode is used when the estimated FRO32K frequency is below 200ppm. In this mode, the measurement is triggered on NBU domain wake up from low power mode using an internal hardware signal. The exponential filter is applied to compute the frequency estimation. If the frequency estimation value is still within 200ppm, the NBU power domain is allowed to go to low power. If the estimated value gets above the 200ppm threshold, the RF SFC switch back to convergence mode. The trim register is updated by one increment (positive or negative) and because the frequency has been adjusted and changed, the estimated filtered frequency is reset to discard all previous measurements. Going back to convergence mode typically happens during a temperature gradient. If the temperature is constant, it is not expected to have the estimated value to go beyond 200ppm so no calibration should be required.

Initialization and configuration During initialization, the RF SFC module will block the Radio Software until monitoring mode is reached. This is to prevent the radio from running with an inaccurate time base due to an important 32k clock frequency error.

Initialization and configuration is done by the NBU core. The configuration parameters can set up:

- The 200ppm target threshold. This value shall be 200ppm or higher.
- The filtering number n (see section above), It shall be between 0 and 8. Default is 7 which is similar to an averaging filter of 128 samples. A higher value will be more robust against noise. A lower value will track temperature variation more faster.

In order to prevent the host application domain from going into power down mode (power down mode not supported with FRO32K as clock source), the fwkSrvLowPowerConstraintCallbacks functions structure is registered to the Framework service on host application core from fwk_platform_lowpower.c file, PLATFORM_LowPowerInit() function. The NBU code applies a low power Deep Sleep constraint to the application core. This constraint is released when the NBU firmware has no activity to do and re-applied when a new activity starts.

Lowpower impact

Power impact during active mode: In monitoring mode (this should be 99.9% of the time if temperature does not vary), the FRO32KHz frequency measurements are performed during a Radio activity so it does not increase the active current as the sources clocks are already active. Also, it does not increase the active time as the measurement takes less time than an advertising event or connection event so no impact on power consumption.

The main power impact will be in convergence mode. In this case, measurements/calibrations are done in loop until the monitoring mode is reached (frequency error less than 200ppm). This could happen:

- During power ON reset,
- When temperature varies: The frequency will deviate from 32768Hz and FRO32K trimming register correction will need to be updated for that,
- When no measurement has been done during some time as we cannot predict if the FRO has drifted, so we discard older values and start convergence mode.

When FRO32K frequency needs to be adjusted, the NBU core will wake-up the main power domain and will update the FRO32K trimming register.

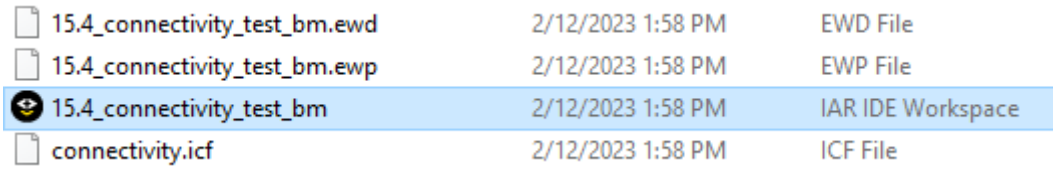
Power impact during low power mode: The power consumption in low power mode will increase slightly due to running FRO32K compared to XTAL32K. The power consumption of FRO32K typically consumes 350nA while it is only 100nA with XTAL32K. Refer to the product datasheet for the exact numbers.

Wireless IEEE

K32W1 / MCXW71 / MCXW72 Connectivity Test Application Getting Started User Guide (UG10204)

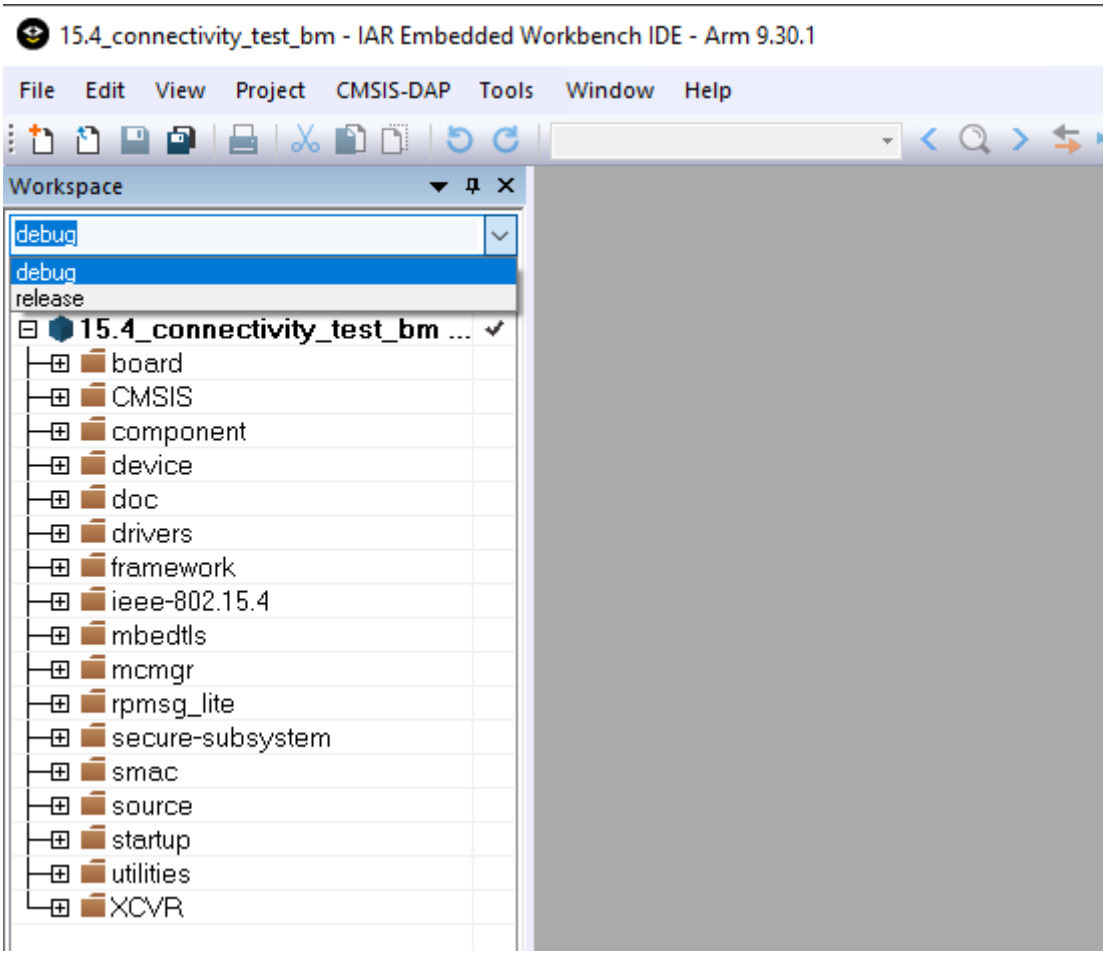
Introduction This document describes briefly how to build the Connectivity Test Application for the Arm Cortex based K32W1, MCXW71, and MCXW72 wireless microcontroller platforms provided by NXP.

Building the binary file This section describes the required steps for obtaining the binary file for usage with the board. The Connectivity Test Application is available in the package location below:



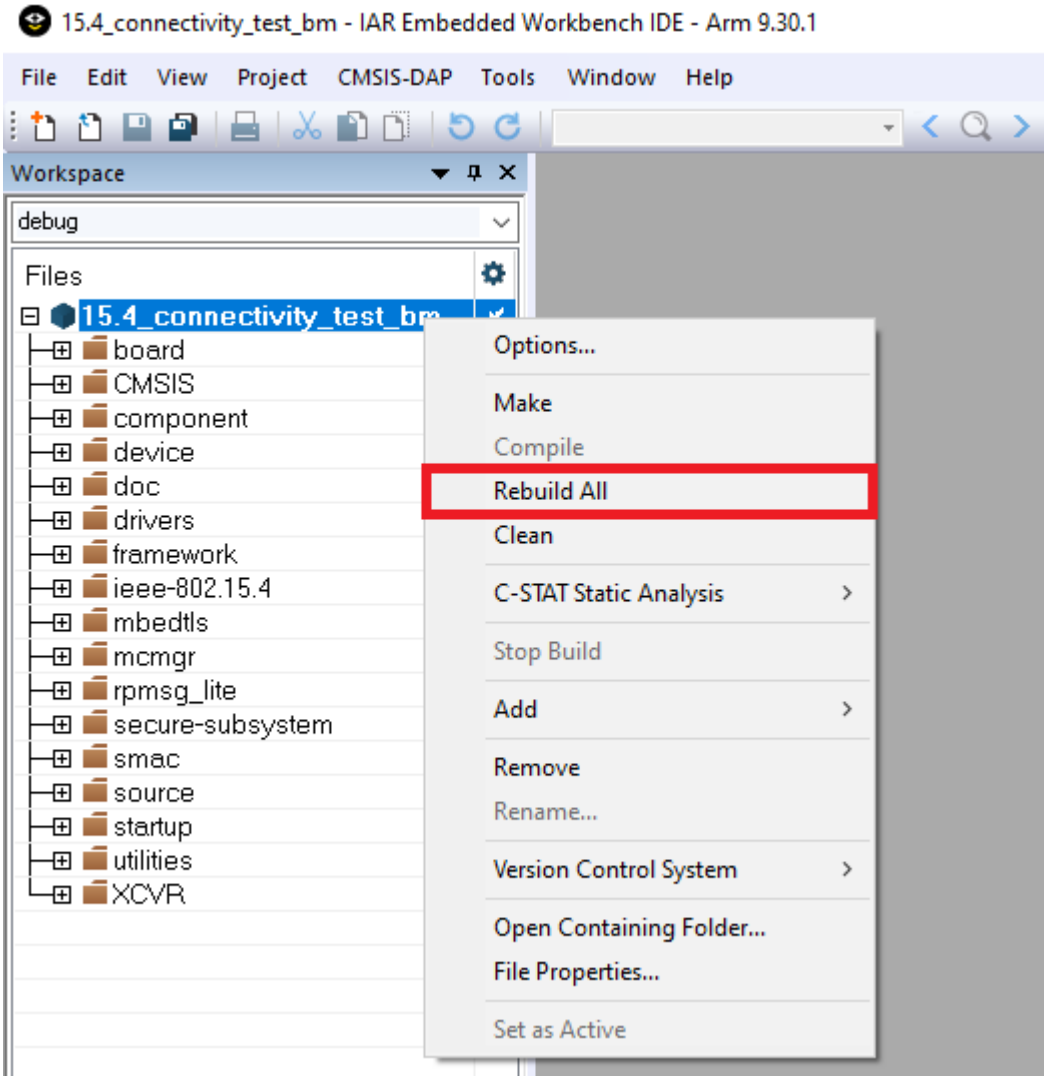
```
<sdk_folder_path>\boards\<board_name>\wireless_examples\ieee-802.15.4\connectivity_test\bm\iar
```

Where <board name> is:

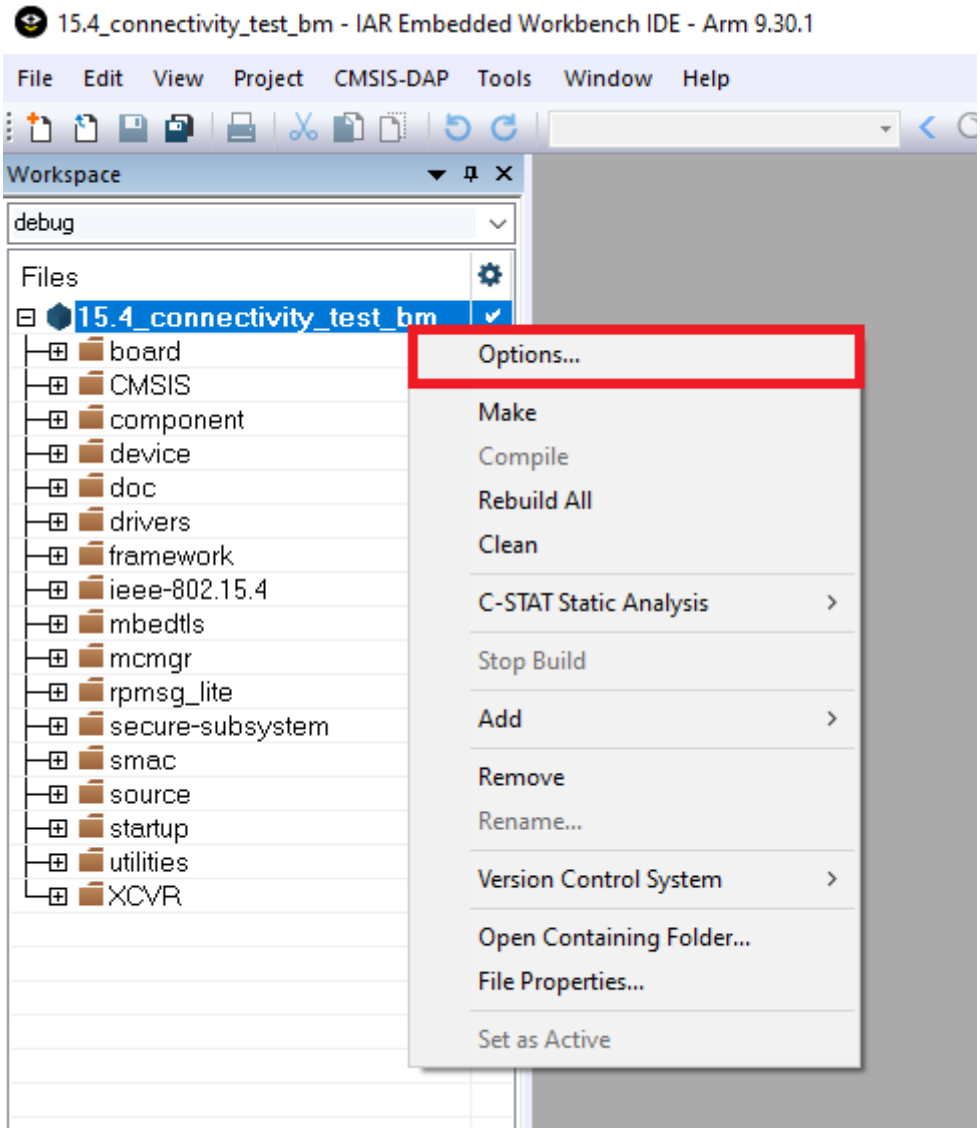


- k32w148evk for K32W1480-EVK
- frdmmcxw71 for FRDM-MCXW71
- frdmmcxw72 for FRDM-MCXW72
- mcxw71evk for MCX-W71-EVK
- mcxw72evk for MCX-W72-EVK

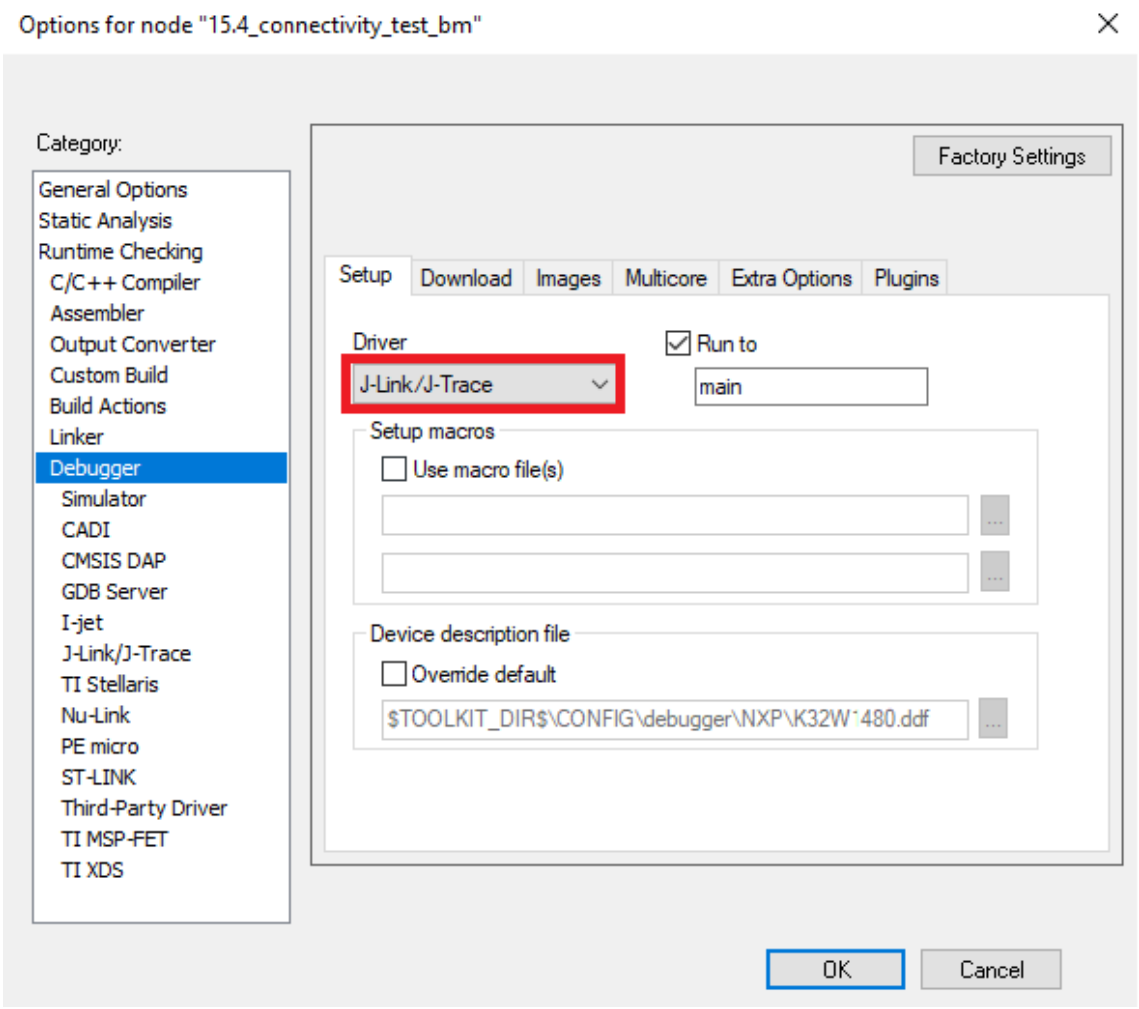
Building and flashing the Connectivity Test application using IAR



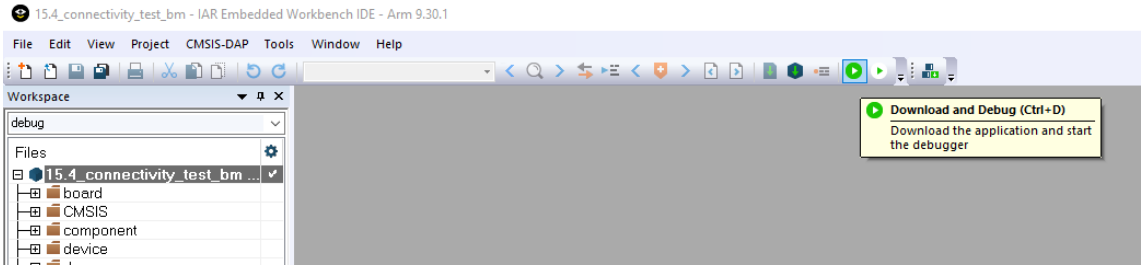
1. **Step 1**: Navigate to the Connectivity Test Application location described above.
2. **Step 2**: Open the highlighted IAR IDE Workspace file (*.eww file format:)



3. **Step 3**:Select the desired configuration for the Connectivity Test Application project:



4. **Step 4**: Build the project.



5. **Step 5**: Make the appropriate debugger settings in the project options window:

15.4_connectivity_test_bm - IAR Embedded Workbench IDE - Arm 9.30.1

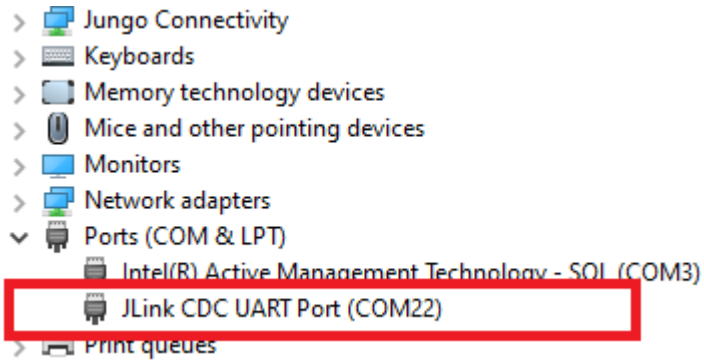
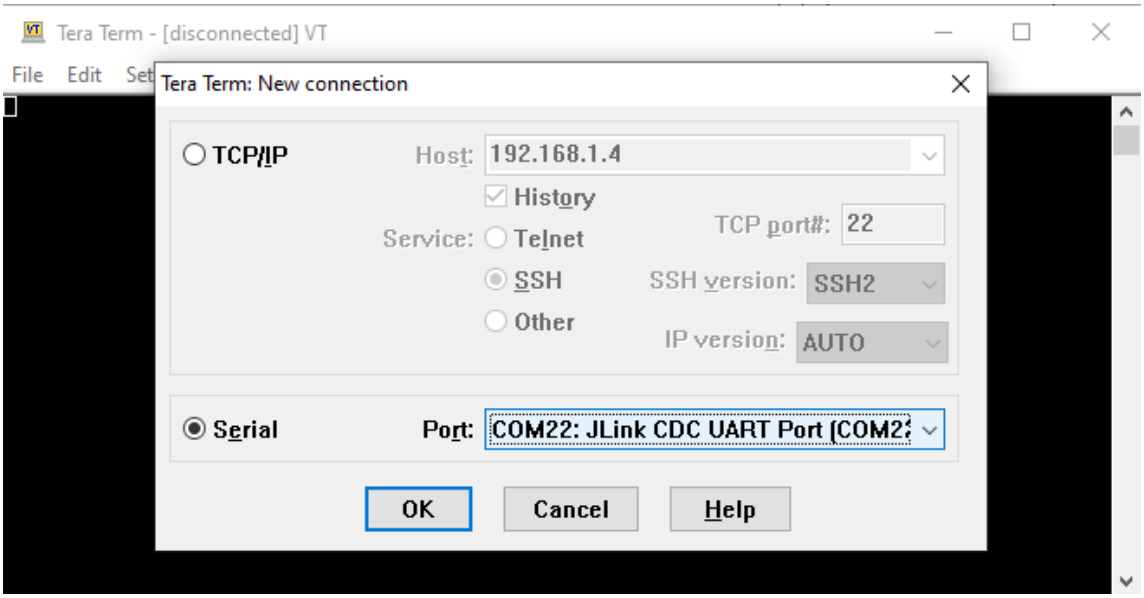
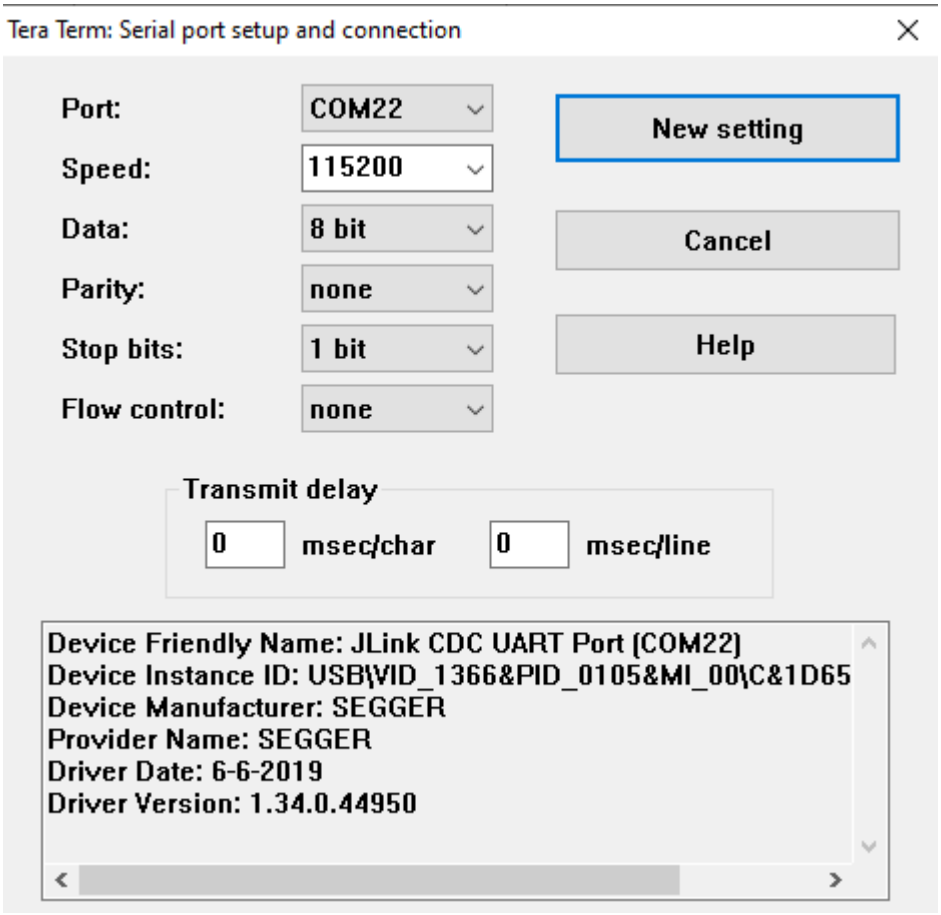
6. **Step 6**: Click the "**Download and Debug**" button to flash the executable onto the board.



Running the Connectivity Test application This section demonstrates the basic steps to run a demo application.

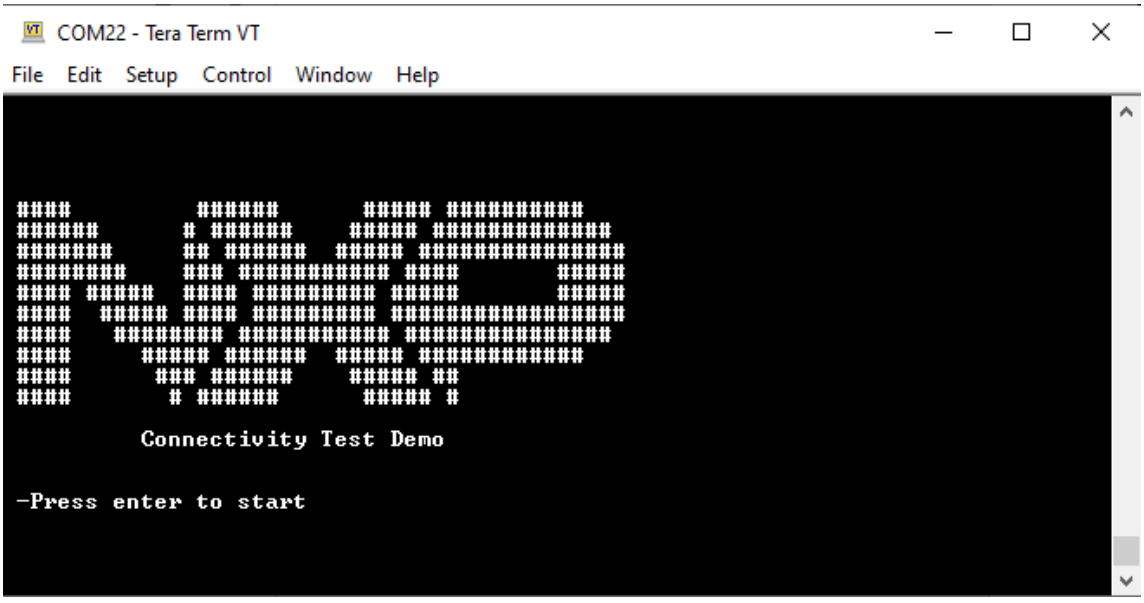


Note: For detailed information about the Connectivity Test Application, refer to the "*Connectivity Test Application Command Line Interface User Guide*" included in the package (*CTA-CLIUG_Rev0.pdf*).



In order to connect to the board, the Connectivity Test application requires a serial terminal program. This example uses Tera Term for this purpose.

1. **Step 1**: Load the application on the board using IAR Embedded Workbench for Arm by clicking "**Download and Debug**".
2. **Step 2**: After loading the application, check "**Device Manager**" to get the serial port number. This should appear with the prefix "**JLink**".



3. **Step 3**: Using the port numbers specified in Device Manager, open a Tera Term instance and connect to the device using the 115200 baud rate. To change the baud rate of the terminal go to the "**Setup**-> **Serial Port**" menu.

4. **Step 4**: Start the application by pressing the "**Enter**" key. Any other key displays the logo screen again.

5. Follow the on-screen instructions to run each test. If a test needs a second platform, follow the steps above to set it up.

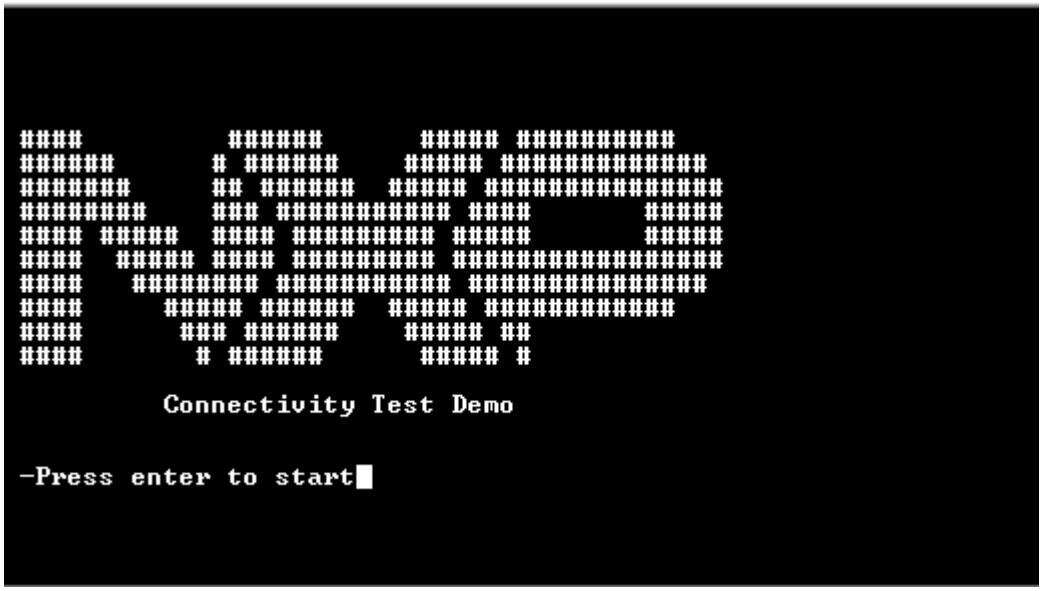
Revision history The table below summarizes the revisions to this document.

Document ID	Release date	Description
UG10204 v.1.0	24 January 2025	Added support for MCXW71 and MCXW72 devices
K32W1CTAGSG v.0.0	27 February 2023	Initial release for K32W1 platform

CTACLIUG

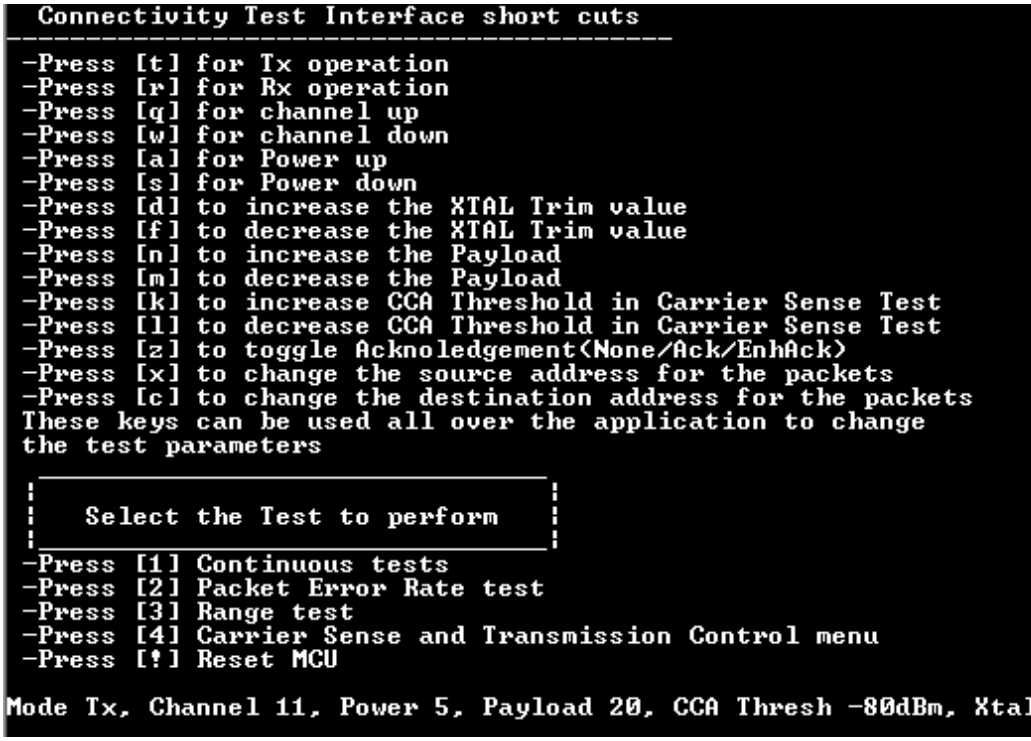
Introduction This document describes the Command Line Interface (CLI) options provided with the **812.15.4 Connectivity Test application**. The application provides tests for measuring transmission between two or more devices. This document also provides the test description, configuration, setup, and steps to perform the test using the application.

Connectivity Test application setup The figure below describes the Connectivity Test Application possible configurations.



Test bed description

- Running the Connectivity Test Demo Application requires a PC and two devices.
- Connectivity Test Application CLI is accessed using the serial port of the devices.
- Some features of the Connectivity Test Application like **Packet Error Rate** or **Range Tests** require the usage of two devices.
- For capturing over the air traffic, an RF sniffer can be used.
- For tests where the output power or the modulated output power of the radio should be measured, a spectrum analyzer should be used.



Parent topic:*Connectivity Test application setup*

Connectivity Test CLI

CLI initialization and description The figure below shows how the Command Line Interface (CLI) menu of the **812.15.4 Connectivity Test application** appears at start-up.

Press "**Enter**" on the message prompt. The full CLI menu is displayed as shown in the figure below.

Connectivity Test Demo CLI

The CLI is divided into three main categories:

1. **Shortcuts**: This category provides configuration options that can be used in the tests performed. Shortcuts can be used within any accessed test menu to change the test parameters.
2. **Tests**: This category provides the test that can be performed. Each test category numbered from 1 to 4 contains additional options.
3. **Device state**: This category indicates the current state of the device. The device state can be modified according to user preference by using the shortcut keys available by the CLI.

Device state is displayed within any test menu and is refreshed every time a shortcut command is issued. Device state is not shown when tests are in progress.

Parent topic:*Connectivity Test CLI*

CLI shortcut command description Commands from this section are used for configuring the device. All the shortcut commands modifications, except **[x]**and **[c]**, are displayed in the device state.

Shortcut commands cover the following configuration settings:

1. **Device operation mode**:
   - **[t]**: configures the device in **transmitter** mode
   - **[r]**: configures the device in **receiver** mode
2. **Channel settings:**
   - Channel number range between [11-26], default value = 11
   - **[q]**:**increments** channel number
   - **[w]**: **decrements** channel number
3. **Output power settings:**
   - Output power range between [0-32], default value = 5
   - **[a]**: **increments** output power
   - **[s]**: **decrements** output power
4. **Crystal trim value settings:**
   - XTAL trim range between [0-127], default value = 0
   - **[d]**: **increases** XTAL trim value
   - **[f]**: **decreases** XTAL trim value
5. **Data payload length settings:**
   - **[n]: increases** the data payload length
   - **[m]**: **decreases** the data payload length
6. **CCA threshold settings:**
   - CCA Threshold range between [0-110], default value=80
   - **[k]**: **increases** CCA Threshold in Carrier Sense Test
   - **[l]**: **decreases** CCA Threshold in Carrier Sense Test
7. **Packet acknowledgment settings:**
   - Default value = NoAck.
   - **[z]**: sets Acknowledgement requirement (NoAck/Ack/EnhancedAck).
8. **Packet source/address settings:**
   - Source address default value = 0xBEAD
   - Destination address default value = 0xFFFF
   - **[x]**: sets **source** address for packets
   - **[c]**: sets **destination** address for packets

Parent topic:*Connectivity Test CLI*

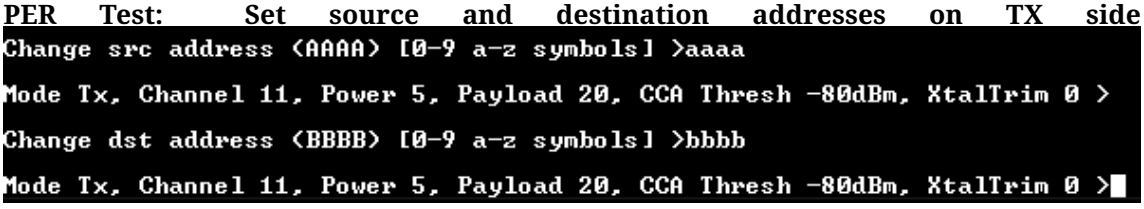
CLI test description Four major test categories are exposed through Connectivity Test Application:

1. **Continuous tests**
2. **Packet Error Rate Test**
3. **Range Test**
4. **Carrier Sense and Transmission Control**

Continuous Test menu The Continuous Test menu displays the following modes of operation:

1. **Idle mode**: This mode sets the transceiver into Idle mode.
2. **Burst PRBS transmission using packet mode**: This mode verifies the transceiver operational state by transmitting over the air a Pseudo Random Binary Sequence payload of 65 bytes.
3. **Continuous modulated transmission**: This mode generates and loads a PRBS9 pattern into transceiver's TX buffer and is used to verify the modulated output power of the transceiver.
4. **Continuous unmodulated transmission**: This mode sets the transceiver to continuously transmit an unmodulated carrier (CW) and is used to measure the output power of the transceiver.
5. **Continuous reception**: This mode sets the transceiver into Receive sequence.
6. **Continuous energy detect**: This mode sets the transceiver to perform the Energy Detection operation. It returns the maximal energy on the specified channel.
7. **Continuous scan**: This mode returns values of Energy Detect operation performed on all RF channels.
8. **Continuous CCA**: This mode performs Continuous Clear Channel Assessment (CCA) procedure and returns whether the specified channel is Busy or Idle.

Parent topic:CLI test description



Packet Error Rate (PER) menu The Packet Error Rate (PER) test mode is used to measure the sensitivity of the radio based on packet reception. The content of this menu is strictly related to the operation mode of the device.

PER test can be performed in three different modes:

1. Transmission *without expected acknowledgement*.
2. Transmission *with expected acknowledgement*.
3. Transmission *with expected enhanced acknowledgement*.

Steps to perform a PER test The steps to perform a PER test procedure are as follows:

1. Set the source and destination address of the transmitter device. For example, source=0xaaaa, destination=0xbbb. (Any other address can be chosen instead.) See the figure below.
   PER Test: Set source and destination addresses on TX side

2. Set the source and destination address of the receiver device. For example, source=0xbbbb, destination=0xaaaa (Any other addresses can be chosen instead). See the figure below.
   PER Test: Set destination and destination addresses on RX side

```
Change src address (BBBB) [0-9 a-z symbols] >bbbb

Mode Rx, Channel 11, Power 5, Payload 20, CCA Thresh -80dBm, XtalTrim 0 >

Change dst address (AAAA) [0-9 a-z symbols] >aaaa

Mode Rx, Channel 11, Power 5, Payload 20, CCA Thresh -80dBm, XtalTrim 0 >
```

3. Set the receiver device to run.
4. Set the transmitter device to run.

Parent topic: Packet Error Rate (PER) menu

Packet error rate when the device is set as transceiver When the device is set to Transmitter mode, it prompts the user to indicate the following:

- The number of packets that should be transmitted during the test.
- The transmission interval between two consecutive packets.

See the figure below. **Configuring PER for TX device with no ACK**

```

```

Parent topic: Packet Error Rate (PER) menu

Parent topic:CLI test description

Range Test menu This is a simple and quick test in which data packets are exchanged between two devices.

- On the transmitter side, the device initiates the data transfer and expects to receive a packet containing the same data payload. An average RSSI calculation is performed based on the incoming packet's RSSI and the number of sent packets. If the receiving packet does not contain the same data payload, RSSI calculation is not performed, and a 'packet dropped' message is shown in CLI.
- On the receiver side, the device sends back the message to originator.

Range tests can be performed in three different modes:

1. Transmission without expected Acknowledgment.
2. Transmission with expected Acknowledgment.
3. Transmission with expected Enhanced Acknowledgment

Steps to perform a Range Test procedure The steps to perform a Range Test procedure are as follows:

1. Set the source and destination address of the transmitter device: source=0xaaaa, destination=0xbbb. (Any other addresses can be chosen). See the figure below. **Range Test: Set the source and destination addresses on TX side**

```
Change src address (AAAA) [0-9 a-z symbols] >aaaa

Mode Tx, Channel 11, Power 5, Payload 20, CCA Thresh -80dBm, XtalTrim 0 >

Change dst address (BBBB) [0-9 a-z symbols] >bbbb

Mode Tx, Channel 11, Power 5, Payload 20, CCA Thresh -80dBm, XtalTrim 0 >
```

2. Set the source and destination address of the receiver device.

   For example, source=0xbbbb, destination=0xaaaa. (Any other addresses can be chosen). See the figure below.
   Range Test: Set the source and destination addresses on RX side

```
Change src address (BBBB) [0-9 a-z symbols] >bbbb

Mode Rx, Channel 11, Power 5, Payload 20, CCA Thresh -80dBm, XtalTrim 0 >

Change dst address (AAAA) [0-9 a-z symbols] >aaaa

Mode Rx, Channel 11, Power 5, Payload 20, CCA Thresh -80dBm, XtalTrim 0 >
```

3. Set the receiver device to run as shown in the figure below. **Range Test: Set the RX device to run**

```
 ____________________________

Parent topic:CLI test description

Carrier Sense and Transmission Control Select menu

Carrier Sense Test with unmodulated input signal This test performs a “manual” Clear Channel Assessment procedure. First, an energy request procedure is done to obtain the RSSI on the specified channel. Then, the obtained RSSI is compared against CCA threshold value, which can be manually set by issuing shortcut commands **[l]**and **[k].**

If the obtained RSSI value for the specified channel is greater than the CCA threshold value, then the channel is considered busy, no transmission is issued on that channel and another energy detect request is started. This is shown in the below figure. **Carrier Sense Test when RSSI is greater than CCA Threshold**

```
 ┌──────────────────────────────────────────────────────┐
 ¦                                                      ¦
 ¦ Radio Carrier Sense and Transmission Control Select Menu ¦
 ¦                                                      ¦
 └──────────────────────────────────────────────────────┘

  -Press [1] Carrier Sense Test with un-modulation input signal
  -Press [2] Transmission Control Test
  -Press [p] Previous Menu

Mode Tx, Channel 11, Power 32, Payload 20, CCA Thresh -102dBm, XtalTrim 0 >

 Press [SPACE] to begin/interrupt test
 Press [p] to return to previous menu

        Sampling done. RSSI value: -101dBm
        Sampling done. RSSI value: -99dBm
        Sampling done. RSSI value: -102dBm
        Sampling done. RSSI value: -102dBm
        Sampling done. RSSI value: -101dBm
        Sampling done. RSSI value: -91dBm
        Sampling done. RSSI value: -101dBm
        Sampling done. RSSI value: -101dBm
        Sampling done. RSSI value: -103dBm
 Transmission Performed
```

However, if the obtained RSSI value for the specified channel is lower than the CCA Threshold value, then the channel is considered as Idle. It indicates that a transmission has occurred and therefore, the test ends. This is shown in in the below figure. **Carrier Sense Test when RSSI is lower than CCA Threshold**

```
 ┌──────────────────────────────────────────────────────┐

 Press [SPACE] to begin/interrupt test
 Press [p] to return to previous menu

       Sampling done. RSSI value: -102dBm
 Transmission Performed
```

Parent topic: Carrier Sense and Transmission Control Select menu

Transmission Control test The Transmission Control test performs data transmissions over the air using user-specified options.

The data payload is composed from a predefined data buffer that copies as many bytes as the 'device state payload data length setting' indicates.

Before any transmission, the test performs an energy detect procedure to obtain the RSSI value of the specified channel. This value is displayed on the side of a message that indicates a message has been sent over the air.

Steps to perform a Transmission Control Test The figure below illustrates the Transmission Control Test menu. **Transmission Control Test menu**

```
 ┌──────────────────────┐
 │     Tr Ctrl Test Menu      │
 └──────────────────────┘

  Choose the amount of packets to send:
 [0] - 1     Packet     [1] - 25    Packets
 [2] - 100   Packets    [3] - 500   Packets
 [4] - 1000  Packets    [5] - 2000  Packets
 [6] - 5000  Packets    [7] - 10000 Packets
 [8] - 65535 Packets

-Press [p] Previous Menu

Mode Tx, Channel 11, Power 5, Payload 20, CCA Thresh -80dBm, XtalTrim 0 >

 Please type InterPacket delay in miliseconds and press [ENTER]
(During test, exit by pressing [SPACE])
```

The process to conduct the Transmission Control Test is as follows:

1. Select the number of packets to be sent.
2. Specify the inter-packet delay. (Transmission delay between two consecutive packets).

The figure shows this process. **Transmission Control Test execution**

```
 Please type InterPacket delay in miliseconds and press [ENTER]
(During test, exit by pressing [SPACE])

10
        Packet number: 1; RSSI value: -104 dBm

        Packet number: 2; RSSI value: -106 dBm

        Packet number: 3; RSSI value: -104 dBm

        Packet number: 4; RSSI value: -104 dBm

        Packet number: 5; RSSI value: -78 dBm

        Packet number: 6; RSSI value: -98 dBm
```

This test also calculates an approximation of time needed to perform the Overhead + Transmission + Energy Detect procedure.

If the inter-packet delay has a value lower than the estimation previously calculated, a corresponding message is shown, and the test finishes the execution as shown in the figure below.
Transmission Control Test – Inter-Packet delay error

```

Chapter 2

RTOS

2.1 FreeRTOS

2.1.1 FreeRTOS kernel

Open source RTOS kernel for small devices.

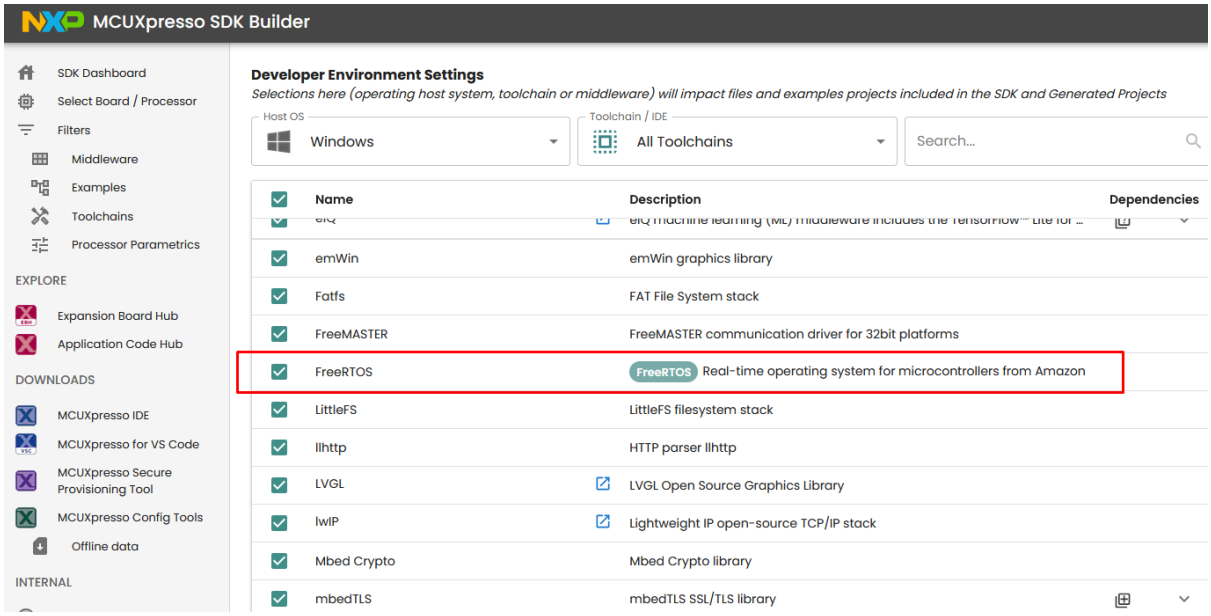
FreeRTOS kernel for MCUXpresso SDK Readme

FreeRTOS kernel for MCUXpresso SDK

Overview The purpose of this document is to describes the FreeRTOS kernel repo integration into the NXP MCUXpresso Software Development Kit: mcuxsdk. MCUXpresso SDK provides a comprehensive development solutions designed to optimize, ease, and help accelerate embedded system development of applications based on MCUs from NXP. This project involves the FreeRTOS kernel repo fork with:

- cmake and Kconfig support to allow the configuration and build in MCUXpresso SDK ecosystem
- FreeRTOS OS additions, such as FreeRTOS driver wrappers, RTOS ready FatFs file system, and the implementation of FreeRTOS tickless mode

The history of changes in FreeRTOS kernel repo for MCUXpresso SDK are summarized in *CHANGELOG_mcuxsdk.md* file.



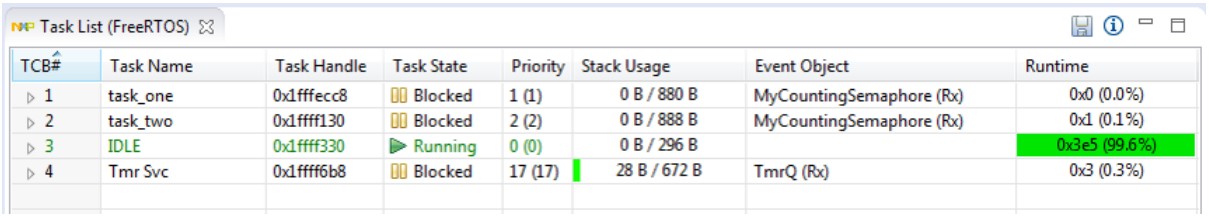
The MCUXpresso SDK framework also contains a set of FreeRTOS examples which show basic FreeRTOS OS features. This makes it easy to start a new FreeRTOS project or begin experimenting with FreeRTOS OS. Selected drivers and middleware are RTOS ready with related FreeRTOS adaptation layer.

FreeRTOS example applications The FreeRTOS examples are written to demonstrate basic FreeRTOS features and the interaction between peripheral drivers and the RTOS.

List of examples The list of freertos_examples, their description and availability for individual supported MCUXpresso SDK development boards can be obtained here: https://mcuxpresso.nxp.com/mcuxsdk/latest/html/examples/freertos_examples/index.html

Location of examples The FreeRTOS examples are located in mcuxsdk-examples repository, see the freertos_examples folder.

Once using MCUXpresso SDK zip packages created via the MCUXpresso SDK Builder the FreeRTOS kernel library and associated freertos_examples are added into final zip package once FreeRTOS components is selected on the Developer Environment Settings page:



The FreeRTOS examples in MCUXpresso SDK zip packages are located in <MCUXpressoSDK_install_dir>/boards/<board_name>/freertos_examples/ subfolders.

Building a FreeRTOS example application For information how to use the cmake and Kconfig based build and configuration system and how to build freertos_examples visit: MCUXpresso SDK documentation for Build And Configuration MCUXpresso SDK Getting Start Guide

Tip: To list all FreeRTOS example projects and targets that can be built via the west build command, use this west list_project command in mcuxsdk workspace:

```
west list_project -p examples/freertos_examples
```

FreeRTOS aware debugger plugin NXP provides FreeRTOS task aware debugger for GDB. The plugin is compatible with Eclipse-based (MCUXpressoIDE) and is available after the installation.

FreeRTOS kernel for MCUXpresso SDK ChangeLog

Changelog FreeRTOS kernel for MCUXpresso SDK All notable changes to this project will be documented in this file.

The format is based on Keep a Changelog, and this project adheres to Semantic Versioning.

[Unreleased]

Added

- Kconfig added CONFIG_FREERTOS_USE_CUSTOM_CONFIG_FRAGMENT config to optionally include custom FreeRTOSConfig fragment
  include file FreeRTOSConfig_frag.h. File must be provided by application.
- Added missing Kconfig option for configUSE_PICOLIBC_TLS.
- Add correct header files to build when configUSE_NEWLIB_REENTRANT and configUSE_PICOLIBC_TLS is selected in config.

[11.1.0_rev0]

- update amazon freertos version

[11.0.1_rev0]

- update amazon freertos version

[10.5.1_rev0]

- update amazon freertos version

[10.4.3_rev1]

- Apply CM33 security fix from 10.4.3-LTS-Patch-2. See rtos\freertos\freertos_kernel\History.txt
- Apply CM33 security fix from 10.4.3-LTS-Patch-1. See rtos\freertos\freertos_kernel\History.txt

[10.4.3_rev0]

- update amazon freertos version.

[10.4.3_rev0]

- update amazon freertos version.

[9.0.0_rev3]

- New features:
  - Tickless idle mode support for Cortex-A7. Add fsl_tickless_epit.c and fsl_tickless_generic.h in portable/IAR/ARM_CA9 folder.
  - Enabled float context saving in IAR for Cortex-A7. Added configUSE_TASK_FPU_SUPPORT macros. Modified port.c and portmacro.h in portable/IAR/ARM_CA9 folder.
- Other changes:
  - Transformed ARM_CM core specific tickless low power support into generic form under freertos/Source/portable/low_power_tickless/.

[9.0.0_rev2]

- New features:
  - Enabled MCUXpresso thread aware debugging. Add freertos_tasks_c_additions.h and configINCLUDE_FREERTOS_TASK_C_ADDITIONS_H and configFREERTOS_MEMORY_SCHEME macros.

[9.0.0_rev1]

- New features:
  - Enabled -flto optimization in GCC by adding **attribute**((used)) for vTaskSwitchContext.
  - Enabled KDS Task Aware Debugger. Apply FreeRTOS patch to enable configRECORD_STACK_HIGH_ADDRESS macro. Modified files are task.c and FreeRTOS.h.

[9.0.0_rev0]

- New features:
  - Example freertos_sem_static.
  - Static allocation support RTOS driver wrappers.
- Other changes:
  - Tickless idle rework. Support for different timers is in separated files (fsl_tickless_systick.c, fsl_tickless_lptmr.c).
  - Removed configuration option configSYSTICK_USE_LOW_POWER_TIMER. Low power timer is now selected by linking of apropriate file fsl_tickless_lptmr.c.
  - Removed configOVERRIDE_DEFAULT_TICK_CONFIGURATION in RVDS port. Use of **attribute**((weak)) is the preferred solution. Not same as _weak!

[8.2.3]

- New features:
  - Tickless idle mode support.
  - Added template application for Kinetis Expert (KEx) tool (template_application).
- Other changes:
  - Folder structure reduction. Keep only Kinetis related parts.

FreeRTOS kernel Readme

MCUXpresso SDK: FreeRTOS kernel This repository is a fork of FreeRTOS kernel (https://github.com/FreeRTOS/FreeRTOS-Kernel)(11.1.0). Modifications have been made to adapt to NXP MCUXpresso SDK. CMakeLists.txt and Kconfig added to enable FreeRTOS kernel repo sources build in MCUXpresso SDK. It is part of the MCUXpresso SDK overall delivery which is composed of several sub-repositories/projects. Navigate to the top/parent repository mcuxsdk-manifests(https://github.com/nxp-mcuxpresso/mcuxsdk-manifests) for the complete delivery of MCUXpresso SDK.

For more information about the FreeRTOS kernel repo adoption see README_mcuxsdk.md: FreeRTOS kernel for MCUXpresso SDK Readme document.

Getting started This repository contains FreeRTOS kernel source/header files and kernel ports only. This repository is referenced as a submodule in FreeRTOS/FreeRTOS repository, which contains pre-configured demo application projects under FreeRTOS/Demo directory.

The easiest way to use FreeRTOS is to start with one of the pre-configured demo application projects. That way you will have the correct FreeRTOS source files included, and the correct include paths configured. Once a demo application is building and executing you can remove the demo application files, and start to add in your own application source files. See the FreeRTOS Kernel Quick Start Guide for detailed instructions and other useful links.

Additionally, for FreeRTOS kernel feature information refer to the Developer Documentation, and API Reference.

Also for contributing and creating a Pull Request please refer to *the instructions here*.

Getting help If you have any questions or need assistance troubleshooting your FreeRTOS project, we have an active community that can help on the FreeRTOS Community Support Forum.

To consume FreeRTOS-Kernel

Consume with CMake If using CMake, it is recommended to use this repository using FetchContent. Add the following into your project's main or a subdirectory's CMakeLists.txt:

- Define the source and version/tag you want to use:

```
FetchContent_Declare( freertos_kernel
  GIT_REPOSITORY https://github.com/FreeRTOS/FreeRTOS-Kernel.git
  GIT_TAG        main #Note: Best practice to use specific git-hash or tagged version
)
```

In case you prefer to add it as a git submodule, do:

```
git submodule add https://github.com/FreeRTOS/FreeRTOS-Kernel.git <path of the submodule>
git submodule update --init
```

- Add a freertos_config library (typically an INTERFACE library) The following assumes the directory structure:
  - include/FreeRTOSConfig.h

```
add_library(freertos_config INTERFACE)

target_include_directories(freertos_config SYSTEM
INTERFACE
    include
)

target_compile_definitions(freertos_config
  INTERFACE
    projCOVERAGE_TEST=0
)
```

In case you installed FreeRTOS-Kernel as a submodule, you will have to add it as a subdirectory:

```
add_subdirectory(${FREERTOS_PATH})
```

- Configure the FreeRTOS-Kernel and make it available
  - this particular example supports a native and cross-compiled build option.

```
set( FREERTOS_HEAP "4" CACHE STRING "" FORCE)
# Select the native compile PORT
set( FREERTOS_PORT "GCC_POSIX" CACHE STRING "" FORCE)
# Select the cross-compile PORT
if (CMAKE_CROSSCOMPILING)
  set(FREERTOS_PORT "GCC_ARM_CA9" CACHE STRING "" FORCE)
endif()

FetchContent_MakeAvailable(freertos_kernel)
```

- In case of cross compilation, you should also add the following to freertos_config:

```
target_compile_definitions(freertos_config INTERFACE ${definitions})
target_compile_options(freertos_config INTERFACE ${options})
```

Consuming stand-alone - Cloning this repository To clone using HTTPS:

```
git clone https://github.com/FreeRTOS/FreeRTOS-Kernel.git
```

Using SSH:

```
git clone git@github.com:FreeRTOS/FreeRTOS-Kernel.git
```

Repository structure

- The root of this repository contains the three files that are common to every port - list.c, queue.c and tasks.c. The kernel is contained within these three files. croutine.c implements the optional co-routine functionality - which is normally only used on very memory limited systems.
- The ./portable directory contains the files that are specific to a particular microcontroller and/or compiler. See the readme file in the ./portable directory for more information.
- The ./include directory contains the real time kernel header files.
- The ./template_configuration directory contains a sample FreeRTOSConfig.h to help jumpstart a new project. See the *FreeRTOSConfig.h* file for instructions.

Code Formatting FreeRTOS files are formatted using the "uncrustify" tool. The configuration file used by uncrustify can be found in the FreeRTOS/CI-CD-GitHub-Actions's uncrustify.cfg file.

Line Endings File checked into the FreeRTOS-Kernel repository use unix-style LF line endings for the best compatibility with git.

For optimal compatibility with Microsoft Windows tools, it is best to enable the git autocrlf feature. You can enable this setting for the current repository using the following command:

```
git config core.autocrlf true
```

Git History Optimizations Some commits in this repository perform large refactors which touch many lines and lead to unwanted behavior when using the git blame command. You can configure git to ignore the list of large refactor commits in this repository with the following command:

```
git config blame.ignoreRevsFile .git-blame-ignore-revs
```

Spelling and Formatting We recommend using Visual Studio Code, commonly referred to as VSCode, when working on the FreeRTOS-Kernel. The FreeRTOS-Kernel also uses cSpell as part of its spelling check. The config file for which can be found at *cspell.config.yaml* There is additionally a cSpell plugin for VSCode that can be used as well. .cSpellWords.txt contains words that are not traditionally found in an English dictionary. It is used by the spellchecker to verify the various jargon, variable names, and other odd words used in the FreeRTOS code base are correct. If your pull request fails to pass the spelling and you believe this is a mistake, then add the word to .cSpellWords.txt. When adding a word please then sort the list, which can be done by running the bash command: `sort -u .cSpellWords.txt -o .cSpellWords.txt` Note that only the FreeRTOS-Kernel Source Files, *include*, *portable/MemMang*, and *portable/Common* files are checked for proper spelling, and formatting at this time.

2.1.2 FreeRTOS drivers

This is set of NXP provided FreeRTOS reentrant bus drivers.

2.1.3 backoffalgorithm

Algorithm for calculating exponential backoff with jitter for network retry attempts.

Readme

MCUXpresso SDK: backoffAlgorithm Library This repository is a fork of backoffAlgorithm library (https://github.com/FreeRTOS/backoffalgorithm)(1.3.0). Modifications have been made to adapt to NXP MCUXpresso SDK. CMakeLists.txt and Kconfig added to enable backoffAlgorithm repo sources build in MCUXpresso SDK. It is part of the MCUXpresso SDK overall delivery which is composed of several sub-repositories/projects. Navigate to the top/parent repository mcuxsdk-manifests(https://github.com/nxp-mcuxpresso/mcuxsdk-manifests) for the complete delivery of MCUXpresso SDK.

backoffAlgorithm Library This repository contains the backoffAlgorithm library, a utility library to calculate backoff period using an exponential backoff with jitter algorithm for retrying network operations (like failed network connection with server). This library uses the "Full Jitter" strategy for the exponential backoff with jitter algorithm. More information about the algorithm can be seen in the Exponential Backoff and Jitter AWS blog.

The backoffAlgorithm library is distributed under the *MIT Open Source License*.

Exponential backoff with jitter is typically used when retrying a failed network connection or operation request with the server. An exponential backoff with jitter helps to mitigate failed network operations with servers, that are caused due to network congestion or high request load on the server, by spreading out retry requests across multiple devices attempting network operations. Besides, in an environment with poor connectivity, a client can get disconnected at any time. A backoff strategy helps the client to conserve battery by not repeatedly attempting reconnections when they are unlikely to succeed.

See memory requirements for this library *here*.

backoffAlgorithm v1.3.0 source code is part of the FreeRTOS 202210.00 LTS release.

backoffAlgorithm v1.0.0 source code is part of the FreeRTOS 202012.00 LTS release.

Reference example The example below shows how to use the backoffAlgorithm library on a POSIX platform to retry a DNS resolution query for amazon.com.

```
#include "backoff_algorithm.h"
#include <stdlib.h>
#include <string.h>
#include <netdb.h>
#include <unistd.h>
#include <time.h>

/* The maximum number of retries for the example code. */
#define RETRY_MAX_ATTEMPTS            ( 5U )

/* The maximum back-off delay (in milliseconds) for between retries in the example. */
#define RETRY_MAX_BACKOFF_DELAY_MS    ( 5000U )

/* The base back-off delay (in milliseconds) for retry configuration in the example. */
#define RETRY_BACKOFF_BASE_MS         ( 500U )

int main()
{
    /* Variables used in this example. */
    BackoffAlgorithmStatus_t retryStatus = BackoffAlgorithmSuccess;
    BackoffAlgorithmContext_t retryParams;
    char serverAddress[] = "amazon.com";
    uint16_t nextRetryBackoff = 0;

    int32_t dnsStatus = -1;
    struct addrinfo hints;
    struct addrinfo ** pListHead = NULL;
    struct timespec tp;

    /* Add hints to retrieve only TCP sockets in getaddrinfo. */
    ( void ) memset( &hints, 0, sizeof( hints ) );

    /* Address family of either IPv4 or IPv6. */
    hints.ai_family = AF_UNSPEC;
    /* TCP Socket. */
    hints.ai_socktype = ( int32_t ) SOCK_STREAM;
    hints.ai_protocol = IPPROTO_TCP;

    /* Initialize reconnect attempts and interval. */
    BackoffAlgorithm_InitializeParams( &retryParams,
                                       RETRY_BACKOFF_BASE_MS,
                                       RETRY_MAX_BACKOFF_DELAY_MS,
                                       RETRY_MAX_ATTEMPTS );

    /* Seed the pseudo random number generator used in this example (with call to
     * rand() function provided by ISO C standard library) for use in backoff period
     * calculation when retrying failed DNS resolution. */

    /* Get current time to seed pseudo random number generator. */
    ( void ) clock_gettime( CLOCK_REALTIME, &tp );
    /* Seed pseudo random number generator with seconds. */
    srand( tp.tv_sec );

    do
    {
        /* Perform a DNS lookup on the given host name. */
        dnsStatus = getaddrinfo( serverAddress, NULL, &hints, pListHead );
```

(continues on next page)

(continued from previous page)

```
        /* Retry if DNS resolution query failed. */
        if( dnsStatus != 0 )
        {
            /* Generate a random number and get back-off value (in milliseconds) for the next retry.
             * Note: It is recommended to use a random number generator that is seeded with
             * device-specific entropy source so that backoff calculation across devices is different
             * and possibility of network collision between devices attempting retries can be avoided.
             *
             * For the simplicity of this code example, the pseudo random number generator, rand()
             * function is used. */
            retryStatus = BackoffAlgorithm_GetNextBackoff( &retryParams, rand(), &nextRetryBackoff );

            /* Wait for the calculated backoff period before the next retry attempt of querying DNS.
             * As usleep() takes nanoseconds as the parameter, we multiply the backoff period by 1000. */
            ( void ) usleep( nextRetryBackoff * 1000U );
        }
    } while( ( dnsStatus != 0 ) && ( retryStatus != BackoffAlgorithmRetriesExhausted ) );

    return dnsStatus;
}
```

Building the library A compiler that supports **C90 or later** such as *gcc* is required to build the library.

Additionally, the library uses a header file introduced in ISO C99, stdint.h. For compilers that do not provide this header file, the *source/include* directory contains *stdint.readme*, which can be renamed to stdint.h to build the backoffAlgorithm library.

For instance, if the example above is copied to a file named example.c, *gcc* can be used like so:

```
gcc -I source/include example.c source/backoff_algorithm.c -o example
./example
```

gcc can also produce an output file to be linked:

```
gcc -I source/include -c source/backoff_algorithm.c
```

Building unit tests

Checkout Unity Submodule By default, the submodules in this repository are configured with update=none in *.gitmodules*, to avoid increasing clone time and disk space usage of other repositories (like amazon-freertos that submodules this repository).

To build unit tests, the submodule dependency of Unity is required. Use the following command to clone the submodule:

```
git submodule update --checkout --init --recursive test/unit-test/Unity
```

Platform Prerequisites

- For running unit tests
  - C89 or later compiler like gcc
  - CMake 3.13.0 or later
- For running the coverage target, gcov is additionally required.

Steps to build Unit Tests

1. Go to the root directory of this repository. (Make sure that the **Unity** submodule is cloned as described *above*.)
2. Create build directory: `mkdir build && cd build`
3. Run *cmake* while inside build directory: `cmake -S ../test`
4. Run this command to build the library and unit tests: `make all`
5. The generated test executables will be present in `build/bin/tests` folder.
6. Run `ctest` to execute all tests and view the test run summary.

Contributing See *CONTRIBUTING.md* for information on contributing.

2.1.4 corehttp

C language HTTP client library designed for embedded platforms.

MCUXpresso SDK: coreHTTP Client Library

This repository is a fork of coreHTTP Client library (https://github.com/FreeRTOS/corehttp)(3.0.0). Modifications have been made to adapt to NXP MCUXpresso SDK. CMakeLists.txt and Kconfig added to enable coreHTTP Client repo sources build in MCUXpresso SDK. It is part of the MCUXpresso SDK overall delivery which is composed of several sub-repositories/projects. Navigate to the top/parent repository mcuxsdk-manifests(https://github.com/nxp-mcuxpresso/mcuxsdk-manifests) for the complete delivery of MCUXpresso SDK.

coreHTTP Client Library

This repository contains a C language HTTP client library designed for embedded platforms. It has no dependencies on any additional libraries other than the standard C library, llhttp, and a customer-implemented transport interface. This library is distributed under the *MIT Open Source License*.

This library has gone through code quality checks including verification that no function has a GNU Complexity score over 8. This library has also undergone both static code analysis from Coverity static analysis, and validation of memory safety and data structure invariance through the CBMC automated reasoning tool.

See memory requirements for this library *here*.

coreHTTP v3.0.0 source code is part of the FreeRTOS 202210.00 LTS release.

coreHTTP v2.0.0 source code is part of the FreeRTOS 202012.00 LTS release.

coreHTTP Config File The HTTP client library exposes configuration macros that are required for building the library. A list of all the configurations and their default values are defined in *core_http_config_defaults.h*. To provide custom values for the configuration macros, a custom config file named `core_http_config.h` can be provided by the user application to the library.

By default, a `core_http_config.h` custom config is required to build the library. To disable this requirement and build the library with default configuration values, provide `HTTP_DO_NOT_USE_CUSTOM_CONFIG` as a compile time preprocessor macro.

The HTTP client library can be built by either:

- Defining a core_http_config.h file in the application, and adding it to the include directories for the library build. **OR**
- Defining the HTTP_DO_NOT_USE_CUSTOM_CONFIG preprocessor macro for the library build.

Building the Library The *httpFilePaths.cmake* file contains the information of all source files and header include paths required to build the HTTP client library.

As mentioned in the *previous section*, either a custom config file (i.e. core_http_config.h) OR HTTP_DO_NOT_USE_CUSTOM_CONFIG macro needs to be provided to build the HTTP client library.

For a CMake example of building the HTTP library with the httpFilePaths.cmake file, refer to the coverity_analysis library target in *test/CMakeLists.txt* file.

Building Unit Tests

Platform Prerequisites

- For running unit tests, the following are required:
  - **C90 compiler** like gcc
  - **CMake 3.13.0 or later**
  - **Ruby 2.0.0 or later** is required for this repository's CMock test framework.
- For running the coverage target, the following are required:
  - **gcov**
  - **lcov**

Steps to build Unit Tests

1. Go to the root directory of this repository.
2. Run the *cmake* command: cmake -S test -B build -DBUILD_CLONE_SUBMODULES=ON
3. Run this command to build the library and unit tests: make -C build all
4. The generated test executables will be present in build/bin/tests folder.
5. Run cd build && ctest to execute all tests and view the test run summary.

CBMC To learn more about CBMC and proofs specifically, review the training material here.

The test/cbmc/proofs directory contains CBMC proofs.

In order to run these proofs you will need to install CBMC and other tools by following the instructions here.

Reference examples The AWS IoT Device SDK for Embedded C repository contains demos of using the HTTP client library here on a POSIX platform. These can be used as reference examples for the library API.

Documentation

Existing Documentation For pre-generated documentation, please see the documentation linked in the locations below:

Location

Note that the latest included version of coreHTTP may differ across repositories.

Generating Documentation The Doxygen references were created using Doxygen version 1.9.2. To generate the Doxygen pages, please run the following command from the root of this repository:

```
doxygen docs/doxygen/config.doxyfile
```

Contributing See *CONTRIBUTING.md* for information on contributing.

2.1.5 corejson

JSON parser.

Readme

MCUXpresso SDK: coreJSON Library This repository is a fork of coreJSON library (https://github.com/FreeRTOS/corejson)(3.2.0). Modifications have been made to adapt to NXP MCUXpresso SDK. CMakeLists.txt and Kconfig added to enable coreJSON repo sources build in MCUXpresso SDK. It is part of the MCUXpresso SDK overall delivery which is composed of several sub-repositories/projects. Navigate to the top/parent repository mcuxsdk-manifests(https://github.com/nxp-mcuxpresso/mcuxsdk-manifests) for the complete delivery of MCUXpresso SDK.

coreJSON Library This repository contains the coreJSON library, a parser that strictly enforces the ECMA-404 JSON standard and is suitable for low memory footprint embedded devices. The coreJSON library is distributed under the *MIT Open Source License*.

This library has gone through code quality checks including verification that no function has a GNU Complexity score over 8, and checks against deviations from mandatory rules in the MISRA coding standard. Deviations from the MISRA C:2012 guidelines are documented under *MISRA Deviations*. This library has also undergone both static code analysis from Coverity static analysis, and validation of memory safety through the CBMC automated reasoning tool.

See memory requirements for this library *here*.

coreJSON v3.2.0 source code is part of the FreeRTOS 202210.00 LTS release.

coreJSON v3.0.0 source code is part of the FreeRTOS 202012.00 LTS release.

Reference example

```
#include <stdio.h>
#include "core_json.h"

int main()
{
    // Variables used in this example.
    JSONStatus_t result;
    char buffer[] = "{\"foo\":\"abc\",\"bar\":{\"foo\":\"xyz\"}}";
    size_t bufferLength = sizeof( buffer ) - 1;
    char queryKey[] = "bar.foo";
    size_t queryKeyLength = sizeof( queryKey ) - 1;
    char * value;
    size_t valueLength;

    // Calling JSON_Validate() is not necessary if the document is guaranteed to be valid.
    result = JSON_Validate( buffer, bufferLength );

    if( result == JSONSuccess )
    {
        result = JSON_Search( buffer, bufferLength, queryKey, queryKeyLength,
                              &value, &valueLength );
    }

    if( result == JSONSuccess )
    {
        // The pointer "value" will point to a location in the "buffer".
        char save = value[ valueLength ];
        // After saving the character, set it to a null byte for printing.
        value[ valueLength ] = '\0';
        // "Found: bar.foo -> xyz" will be printed.
        printf( "Found: %s -> %s\n", queryKey, value );
        // Restore the original character.
        value[ valueLength ] = save;
    }

    return 0;
}
```

A search may descend through nested objects when the queryKey contains matching key strings joined by a separator, .. In the example above, bar has the value {"foo":"xyz"}. Therefore, a search for query key bar.foo would output xyz.

Building coreJSON A compiler that supports **C90 or later** such as *gcc* is required to build the library.

Additionally, the library uses 2 header files introduced in ISO C99, stdbool.h and stdint.h. For compilers that do not provide this header file, the *source/include* directory contains *stdbool.readme* and *stdint.readme*, which can be renamed to stdbool.h and stdint.h respectively.

For instance, if the example above is copied to a file named example.c, *gcc* can be used like so:

```
gcc -I source/include example.c source/core_json.c -o example
./example
```

gcc can also produce an output file to be linked:

```
gcc -I source/include -c source/core_json.c
```

Documentation

Existing documentation For pre-generated documentation, please see the documentation linked in the locations below:

Location
AWS IoT Device SDK for Embedded C FreeRTOS.org

Note that the latest included version of the coreJSON library may differ across repositories.

Generating documentation The Doxygen references were created using Doxygen version 1.9.2. To generate the Doxygen pages, please run the following command from the root of this repository:

```
doxygen docs/doxygen/config.doxyfile
```

Building unit tests

Checkout Unity Submodule By default, the submodules in this repository are configured with `update=none` in *.gitmodules*, to avoid increasing clone time and disk space usage of other repositories (like amazon-freertos that submodules this repository).

To build unit tests, the submodule dependency of Unity is required. Use the following command to clone the submodule:

```
git submodule update --checkout --init --recursive test/unit-test/Unity
```

Platform Prerequisites

- For running unit tests
  - C90 compiler like gcc
  - CMake 3.13.0 or later
  - Ruby 2.0.0 or later is additionally required for the Unity test framework (that we use).
- For running the coverage target, gcov is additionally required.

Steps to build Unit Tests

1. Go to the root directory of this repository. (Make sure that the **Unity** submodule is cloned as described *above*.)
2. Create build directory: `mkdir build && cd build`
3. Run *cmake* while inside build directory: `cmake -S ../test`
4. Run this command to build the library and unit tests: `make all`
5. The generated test executables will be present in `build/bin/tests` folder.
6. Run `ctest` to execute all tests and view the test run summary.

CBMC To learn more about CBMC and proofs specifically, review the training material here.

The test/cbmc/proofs directory contains CBMC proofs.

In order to run these proofs you will need to install CBMC and other tools by following the instructions here.

Contributing See *CONTRIBUTING.md* for information on contributing.

2.1.6 coremqtt

MQTT publish/subscribe messaging library.

MCUXpresso SDK: coreMQTT Library

This repository is a fork of coreMQTT library (https://github.com/FreeRTOS/coremqtt)(2.1.1). Modifications have been made to adapt to NXP MCUXpresso SDK. CMakeLists.txt and Kconfig added to enable coreMQTT repo sources build in MCUXpresso SDK. It is part of the MCUXpresso SDK overall delivery which is composed of several sub-repositories/projects. Navigate to the top/parent repository mcuxsdk-manifests(https://github.com/nxp-mcuxpresso/mcuxsdk-manifests) for the complete delivery of MCUXpresso SDK.

coreMQTT Client Library

This repository contains the coreMQTT library that has been optimized for a low memory footprint. The coreMQTT library is compliant with the MQTT 3.1.1 standard. It has no dependencies on any additional libraries other than the standard C library, a customer-implemented network transport interface, and *optionally* a user-implemented platform time function. This library is distributed under the *MIT Open Source License*.

This library has gone through code quality checks including verification that no function has a GNU Complexity score over 8, and checks against deviations from mandatory rules in the MISRA coding standard. Deviations from the MISRA C:2012 guidelines are documented under *MISRA Deviations*. This library has also undergone both static code analysis from Coverity static analysis, and validation of memory safety through the CBMC automated reasoning tool.

See memory requirements for this library *here*.

coreMQTT v2.1.1 source code is part of the FreeRTOS 202210.01 LTS release.

MQTT Config File The MQTT client library exposes build configuration macros that are required for building the library. A list of all the configurations and their default values are defined in *core_mqtt_config_defaults.h*. To provide custom values for the configuration macros, a custom config file named core_mqtt_config.h can be provided by the application to the library.

By default, a core_mqtt_config.h custom config is required to build the library. To disable this requirement and build the library with default configuration values, provide MQTT_DO_NOT_USE_CUSTOM_CONFIG as a compile time preprocessor macro.

Thus, the MQTT library can be built by either:

- Defining a core_mqtt_config.h file in the application, and adding it to the include directories list of the library
  OR
- Defining the MQTT_DO_NOT_USE_CUSTOM_CONFIG preprocessor macro for the library build.

Sending metrics to AWS IoT When establishing a connection with AWS IoT, users can optionally report the Operating System, Hardware Platform and MQTT client version information of their device to AWS. This information can help AWS IoT provide faster issue resolution and technical support. If users want to report this information, they can send a specially formatted string (see below) in the username field of the MQTT CONNECT packet.

Format

The format of the username string with metrics is:

```
<Actual_Username>?SDK=<OS_Name>&Version=<OS_Version>&Platform=<Hardware_Platform>&
↪MQTTLib=<MQTT_Library_name>@<MQTT_Library_version>
```

Where

- <Actual_Username> is the actual username used for authentication, if username and password are used for authentication. When username and password based authentication is not used, this is an empty value.
- <OS_Name> is the Operating System the application is running on (e.g. FreeRTOS)
- <OS_Version> is the version number of the Operating System (e.g. V10.4.3)
- <Hardware_Platform> is the Hardware Platform the application is running on (e.g. WinSim)
- <MQTT_Library_name> is the MQTT Client library being used (e.g. coreMQTT)
- <MQTT_Library_version> is the version of the MQTT Client library being used (e.g. 1.0.2)

Example

- Actual_Username = “iotuser”, OS_Name = FreeRTOS, OS_Version = V10.4.3, Hardware_Platform_Name = WinSim, MQTT_Library_Name = coremqtt, MQTT_Library_version = 2.1.1. If username is not used, then “iotuser” can be removed.

```
/* Username string:
 * iotuser?SDK=FreeRTOS&Version=v10.4.3&Platform=WinSim&MQTTLib=coremqtt@2.1.1
 */

#define OS_NAME                    ”FreeRTOS”
#define OS_VERSION                 ”V10.4.3”
#define HARDWARE_PLATFORM_NAME     ”WinSim”
#define MQTT_LIB                   ”coremqtt@2.1.1”

#define USERNAME_STRING            ”iotuser?SDK=” OS_NAME ”&Version=” OS_VERSION ”&
↪Platform=” HARDWARE_PLATFORM_NAME ”&MQTTLib=” MQTT_LIB
#define USERNAME_STRING_LENGTH     ( ( uint16_t ) ( sizeof( USERNAME_STRING ) - 1 ) )

MQTTConnectInfo_t connectInfo;
connectInfo.pUserName = USERNAME_STRING;
connectInfo.userNameLength = USERNAME_STRING_LENGTH;
mqttStatus = MQTT_Connect( pMqttContext, &connectInfo, NULL, CONNACK_RECV_TIMEOUT_MS,␣
↪pSessionPresent );
```

Upgrading to v2.0.0 and above With coreMQTT versions >=v2.0.0, there are breaking changes. Please refer to the *coreMQTT version >=v2.0.0 Migration Guide*.

Building the Library The *mqttFilePaths.cmake* file contains the information of all source files and the header include path required to build the MQTT library.

Additionally, the MQTT library requires two header files that are not part of the ISO C90 standard library, stdbool.h and stdint.h. For compilers that do not provide these header files, the

source/include directory contains the files *stdbool.readme* and *stdint.readme*, which can be renamed to stdbool.h and stdint.h, respectively, to provide the type definitions required by MQTT.

As mentioned in the previous section, either a custom config file (i.e. core_mqtt_config.h) OR MQTT_DO_NOT_USE_CUSTOM_CONFIG macro needs to be provided to build the MQTT library.

For a CMake example of building the MQTT library with the mqttFilePaths.cmake file, refer to the coverity_analysis library target in *test/CMakeLists.txt* file.

Building Unit Tests

Checkout CMock Submodule By default, the submodules in this repository are configured with update=none in *.gitmodules* to avoid increasing clone time and disk space usage of other repositories (like amazon-freertos that submodules this repository).

To build unit tests, the submodule dependency of CMock is required. Use the following command to clone the submodule:

```
git submodule update --checkout --init --recursive test/unit-test/CMock
```

Platform Prerequisites

- Docker

or the following:

- For running unit tests
  - **C90 compiler** like gcc
  - **CMake 3.13.0 or later**
  - **Ruby 2.0.0 or later** is additionally required for the CMock test framework (that we use).
- For running the coverage target, **gcov** and **lcov** are additionally required.

Steps to build Unit Tests

1. If using docker, launch the container:
   1. docker build -t coremqtt .
   2. docker run -it -v "$PWD":/workspaces/coreMQTT -w /workspaces/coreMQTT coremqtt
2. Go to the root directory of this repository. (Make sure that the **CMock** submodule is cloned as described *above*)
3. Run the *cmake* command: cmake -S test -B build
4. Run this command to build the library and unit tests: make -C build all
5. The generated test executables will be present in build/bin/tests folder.
6. Run cd build && ctest to execute all tests and view the test run summary.

CBMC To learn more about CBMC and proofs specifically, review the training material here.

The test/cbmc/proofs directory contains CBMC proofs.

In order to run these proofs you will need to install CBMC and other tools by following the instructions here.

Reference examples Please refer to the demos of the MQTT client library in the following locations for reference examples on POSIX and FreeRTOS platforms:

Platform	Location	Transport Interface Implementation
POSIX	AWS IoT Device SDK for Embedded C	POSIX sockets for TCP/IP and OpenSSL for TLS stack
FreeRTOS	FreeRTOS/FreeRTOS	FreeRTOS+TCP for TCP/IP and mbedTLS for TLS stack
FreeRTOS	FreeRTOS AWS Reference Integrations	Based on Secure Sockets Abstraction

Documentation

Note that the latest included version of coreMQTT may differ across repositories.

Generating Documentation The Doxygen references were created using Doxygen version 1.9.2. To generate the Doxygen pages, please run the following command from the root of this repository:

```
doxygen docs/doxygen/config.doxyfile
```

Contributing See *CONTRIBUTING.md* for information on contributing.

2.1.7 coremqtt-agent

The coreMQTT Agent library is a high level API that adds thread safety to the coreMQTT library.

Readme

MCUXpresso SDK: coreMQTT Agent Library This repository is a fork of coreMQTT Agent library (https://github.com/FreeRTOS/coremqtt-agent)(1.2.0). Modifications have been made to adapt to NXP MCUXpresso SDK. CMakeLists.txt and Kconfig added to enable coreMQTT Agent repo sources build in MCUXpresso SDK. It is part of the MCUXpresso SDK overall delivery which is composed of several sub-repositories/projects. Navigate to the top/parent repository mcuxsdk-manifests(https://github.com/nxp-mcuxpresso/mcuxsdk-manifests) for the complete delivery of MCUXpresso SDK.

coreMQTT Agent Library The coreMQTT Agent library is a high level API that adds thread safety to the coreMQTT library. The library provides thread safe equivalents to the coreMQTT's APIs, greatly simplifying its use in multi-threaded environments. The coreMQTT Agent library manages the MQTT connection by serializing the access to the coreMQTT library and reducing implementation overhead (e.g., removing the need for the application to repeatedly call to MQTT_ProcessLoop). This allows your multi-threaded applications to share the same MQTT connection, and enables you to design an embedded application without having to worry about coreMQTT thread safety.

This library has gone through code quality checks including verification that no function has a GNU Complexity score over 8, and checks against deviations from mandatory rules in the MISRA coding standard. Deviations from the MISRA C:2012 guidelines are documented under *MISRA Deviations*. This library has also undergone both static code analysis from Coverity static analysis, and validation of memory safety through the CBMC automated reasoning tool.

See memory requirements for this library *here*.

Cloning this repository This repo uses Git Submodules to bring in dependent components.

To clone using HTTPS:

```
git clone https://github.com/FreeRTOS/coreMQTT-Agent.git --recurse-submodules
```

Using SSH:

```
git clone git@github.com:FreeRTOS/coreMQTT-Agent.git --recurse-submodules
```

If you have downloaded the repo without using the --recurse-submodules argument, you need to run:

```
git submodule update --init --recursive
```

coreMQTT Agent Library Configurations The MQTT Agent library uses the same core_mqtt_config.h configuration file as coreMQTT, with the addition of configuration constants listed at the top of *core_mqtt_agent.h* and *core_mqtt_agent_command_functions.h*. Documentation for these configurations can be found here.

To provide values for these configuration values, they must be either:

- Defined in core_mqtt_config.h used by coreMQTT **OR**
- Passed as compile time preprocessor macros

Porting the coreMQTT Agent Library In order to use the MQTT Agent library on a platform, you need to supply thread safe functions for the agent's *messaging interface*.

Messaging Interface Each of the following functions must be thread safe.

Function Pointer	Description
MQTTAgentMessageSend_t	A function that sends commands (as MQTTAgentCommand_t * pointers) to be received by MQTTAgent_CommandLoop. This can be implemented by pushing to a thread safe queue.
MQTTAgentMessageRecv_t	A function used by MQTTAgent_CommandLoop to receive MQTTAgentCommand_t * pointers that were sent by API functions. This can be implemented by receiving from a thread safe queue.
MQTTAgentCommandGet_t	A function that returns a pointer to an allocated MQTTAgentCommand_t structure, which is used to hold information and arguments for a command to be executed in MQTTAgent_CommandLoop(). If using dynamic memory, this can be implemented using malloc().
MQTTAgentCommandRelease_t	A function called to indicate that a command structure that had been allocated with the MQTTAgentCommandGet_t function pointer will no longer be used by the agent, so it may be freed or marked as not in use. If using dynamic memory, this can be implemented with free().

Reference implementations for the interface functions can be found in the *reference examples* below.

Additional Considerations

Static Memory If only static allocation is used, then the MQTTAgentCommandGet_t and MQTTAgentCommandRelease_t could instead be implemented with a pool of MQTTAgentCommand_t structures, with a queue or semaphore used to control access and provide thread safety. The below *reference examples* use static memory with a command pool.

Subscription Management The MQTT Agent does not track subscriptions for MQTT topics. The receipt of any incoming PUBLISH packet will result in the invocation of a single MQTTAgentIncomingPublishCallback_t callback, which is passed to MQTTAgent_Init() for initialization. If it is desired for different handlers to be invoked for different incoming topics, then the publish callback will have to manage subscriptions and fan out messages. A platform independent subscription manager example is implemented in the *reference examples* below.

Building the Library You can build the MQTT Agent source files that are in the *source* directory, and add *source/include* to your compiler's include path. Additionally, the MQTT Agent library requires the coreMQTT library, whose files follow the same source/ and source/include pattern as the agent library; its build instructions can be found here.

If using CMake, the *mqttAgentFilePaths.cmake* file contains the above information of the source files and the header include path from this repository. The same information is found for coreMQTT from mqttFilePaths.cmake in the *coreMQTT submodule*.

For a CMake example of building the MQTT Agent library with the mqttAgentFilePaths.cmake file, refer to the coverity_analysis library target in *test/CMakeLists.txt* file.

Building Unit Tests

Checkout CMock Submodule To build unit tests, the submodule dependency of CMock is required. Use the following command to clone the submodule:

```
git submodule update --checkout --init --recursive test/unit-test/CMock
```

Unit Test Platform Prerequisites

- For running unit tests
  - **C90 compiler** like gcc
  - **CMake 3.13.0 or later**
  - **Ruby 2.0.0 or later** is additionally required for the CMock test framework (that we use).
- For running the coverage target, **gcov** and **lcov** are additionally required.

Steps to build Unit Tests

1. Go to the root directory of this repository. (Make sure that the **CMock** submodule is cloned as described *above*)
2. Run the *cmake* command: `cmake -S test -B build`
3. Run this command to build the library and unit tests: `make -C build all`
4. The generated test executables will be present in `build/bin/tests` folder.
5. Run `cd build && ctest` to execute all tests and view the test run summary.

CBMC To learn more about CBMC and proofs specifically, review the training material here.

The `test/cbmc/proofs` directory contains CBMC proofs.

In order to run these proofs you will need to install CBMC and other tools by following the instructions here.

Reference examples Please refer to the demos of the MQTT Agent library in the following locations for reference examples on FreeRTOS platforms:

Location
coreMQTT Agent Demos FreeRTOS/FreeRTOS

Documentation The MQTT Agent API documentation can be found here.

Generating documentation The Doxygen references were created using Doxygen version 1.9.2. To generate the Doxygen pages yourself, please run the following command from the root of this repository:

```
doxygen docs/doxygen/config.doxyfile
```

Getting help You can use your Github login to get support from both the FreeRTOS community and directly from the primary FreeRTOS developers on our active support forum. You can find a list of frequently asked questions here.

License This library is licensed under the MIT License. See the *LICENSE* file.

2.1.8 corepkcs11

PKCS #11 key management library.

Readme

MCUXpresso SDK: corePKCS11 Library This repository is a fork of PKCS #11 key management library (https://github.com/FreeRTOS/corePKCS11/tree/v3.5.0)(v3.5.0). Modifications have been made to adapt to NXP MCUXpresso SDK. CMakeLists.txt and Kconfig added to enable corepkcs11 repo sources build in MCUXpresso SDK. It is part of the MCUXpresso SDK overall delivery which is composed of several sub-repositories/projects. Navigate to the top/parent repository mcuxsdk-manifests(https://github.com/nxp-mcuxpresso/mcuxsdk-manifests) for the complete delivery of MCUXpresso SDK.

corePKCS11 Library PKCS #11 is a standardized and widely used API for manipulating common cryptographic objects. It is important because the functions it specifies allow application software to use, create, modify, and delete cryptographic objects, without ever exposing those objects to the application's memory. For example, FreeRTOS AWS reference integrations use a small subset of the PKCS #11 API to, among other things, access the secret (private) key necessary to create a network connection that is authenticated and secured by the Transport Layer Security (TLS) protocol – without the application ever 'seeing' the key.

The Cryptoki or PKCS #11 standard defines a platform-independent API to manage and use cryptographic tokens. The name, "PKCS #11", is used interchangeably to refer to the API itself and the standard which defines it.

This repository contains a software based mock implementation of the PKCS #11 interface (API) that uses the cryptographic functionality provided by Mbed TLS. Using a software mock enables rapid development and flexibility, but it is expected that the mock be replaced by an implementation specific to your chosen secure key storage in production devices.

Only a subset of the PKCS #11 standard is implemented, with a focus on operations involving asymmetric keys, random number generation, and hashing.

The targeted use cases include certificate and key management for TLS authentication and code-sign signature verification, on small embedded devices.

corePKCS11 is implemented on PKCS #11 v2.4.0, the full PKCS #11 standard can be found on the oasis website.

This library has gone through code quality checks including verification that no function has a GNU Complexity score over 8, and checks against deviations from mandatory rules in the MISRA coding standard. Deviations from the MISRA C:2012 guidelines are documented under *MISRA Deviations*. This library has also undergone both static code analysis from Coverity static analysis and validation of memory safety through the CBMC automated reasoning tool.

See memory requirements for this library *here*.

corePKCS11 v3.5.0 source code is part of the FreeRTOS 202210.00 LTS release.

corePKCS11 v3.0.0 source code is part of the FreeRTOS 202012.00 LTS release.

Purpose Generally vendors for secure cryptoprocessors such as Trusted Platform Module (TPM), Hardware Security Module (HSM), Secure Element, or any other type of secure hardware enclave, distribute a PKCS #11 implementation with the hardware. The purpose of the corePKCS11 software only mock library is therefore to provide a non hardware specific PKCS #11 implementation that allows for rapid prototyping and development before switching to a cryptoprocessor specific PKCS #11 implementation in production devices.

Since the PKCS #11 interface is defined as part of the PKCS #11 specification replacing this library with another implementation should require little porting effort, as the interface will not change. The system tests distributed in this repository can be leveraged to verify the behavior of a different implementation is similar to corePKCS11.

corePKCS11 Configuration The corePKCS11 library exposes preprocessor macros which must be defined prior to building the library. A list of all the configurations and their default values are defined in the doxygen documentation for this library.

Build Prerequisites

Library Usage For building the library the following are required:

- **A C99 compiler**
- **mbedcrypto** library from mbedtls version 2.x or 3.x.
- **pkcs11 API header(s)** available from OASIS or OpenSC

Optionally, variables from the pkcsFilePaths.cmake file may be referenced if your project uses cmake.

Integration and Unit Tests In order to run the integration and unit test suites the following are dependencies are necessary:

- **C Compiler**
- **CMake 3.13.0 or later**
- **Ruby 2.0.0 or later** required by CMock.
- **Python 3** required for configuring mbedtls.
- **git** required for fetching dependencies.
- **GNU Make** or **Ninja**

The *mbedtls*, *CMock*, and *Unity* libraries are downloaded and built automatically using the cmake FetchContent feature.

Coverage Measurement and Instrumentation The following software is required to run the coverage target:

- Linux, MacOS, or another POSIX-like environment.
- A recent version of **GCC** or **Clang** with support for gcov-like coverage instrumentation.
- **gcov** binary corresponding to your chosen compiler
- **lcov** from the Linux Test Project
- **perl** needed to run the lcov utility.

Coverage builds are validated on recent versions of Ubuntu Linux.

Running the Integration and Unit Tests

1. Navigate to the root directory of this repository in your shell.
2. Run **cmake** to construct a build tree: `cmake -S test -B build`
   - You may specify your preferred build tool by appending `-G'Unix Makefiles'` or `-GNinja` to the command above.
   - You may append `-DUNIT_TESTS=0` or `-DSYSTEM_TESTS=0` to disable Unit Tests or Integration Tests respectively.
3. Build the test binaries: `cmake --build ./build --target all`
4. Run `ctest --test-dir ./build` or `cmake --build ./build --target test` to run the tests without capturing coverage.
5. Run `cmake --build ./build --target coverage` to run the tests and capture coverage data.

CBMC To learn more about CBMC and proofs specifically, review the training material here.

The `test/cbmc/proofs` directory contains CBMC proofs.

In order to run these proofs you will need to install CBMC and other tools by following the instructions here.

Reference examples The FreeRTOS-Labs repository contains demos using the PKCS #11 library here using FreeRTOS on the Windows simulator platform. These can be used as reference examples for the library API.

Porting Guide Documentation for porting corePKCS11 to a new platform can be found on the AWS docs web page.

corePKCS11 is not meant to be ported to projects that have a TPM, HSM, or other hardware for offloading crypto-processing. This library is specifically meant to be used for development and prototyping.

Related Example Implementations These projects implement the PKCS #11 interface on real hardware and have similar behavior to corePKCS11. It is preferred to use these, over corePKCS11, as they allow for offloading Cryptography to separate hardware.

- ARM's Platform Security Architecture.
- Microchip's cryptoauthlib.
- Infineon's Optiga Trust X.

Documentation

Existing Documentation For pre-generated documentation, please see the documentation linked in the locations below:

Location
AWS IoT Device SDK for Embedded C
FreeRTOS.org

Note that the latest included version of corePKCS11 may differ across repositories.

Generating Documentation The Doxygen references were created using Doxygen version 1.9.2. To generate the Doxygen pages, please run the following command from the root of this repository:

```
doxygen docs/doxygen/config.doxyfile
```

Security See *CONTRIBUTING* for more information.

License This library is licensed under the MIT-0 License. See the LICENSE file.

2.1.9 freertos-plus-tcp

Open source RTOS FreeRTOS Plus TCP.

Readme

MCUXpresso SDK: FreeRTOS-Plus-TCP Library This repository is a fork of FreeRTOS-Plus-TCP library (https://github.com/FreeRTOS/freertos-plus-tcp)(4.0.0). Modifications have been made to adapt to NXP MCUXpresso SDK. CMakeLists.txt and Kconfig added to enable FreeRTOS-Plus-TCP repo sources build in MCUXpresso SDK. It is part of the MCUXpresso SDK overall delivery which is composed of several sub-repositories/projects. Navigate to the top/parent repository mcuxsdk-manifests(https://github.com/nxp-mcuxpresso/mcuxsdk-manifests) for the complete delivery of MCUXpresso SDK.

Introduction This branch contains unified IPv4 and IPv6 functionalities. Refer to the Getting started Guide (found here) for more details.

FreeRTOS-Plus-TCP Library FreeRTOS-Plus-TCP is a lightweight TCP/IP stack for FreeRTOS. It provides a familiar Berkeley sockets interface, making it as simple to use and learn as possible. FreeRTOS-Plus-TCP's features and RAM footprint are fully scalable, making FreeRTOS-Plus-TCP equally applicable to smaller lower throughput microcontrollers as well as larger higher throughput microprocessors.

This library has undergone static code analysis and checks for compliance with the MISRA coding standard. Any deviations from the MISRA C:2012 guidelines are documented under MISRA Deviations. The library is validated for memory safety and data structure invariance through the CBMC automated reasoning tool for the functions that parse data originating from the network. The library is also protocol tested using Maxwell protocol tester for both IPv4 and IPv6.

Getting started The easiest way to use the 4.0.0 version of FreeRTOS-Plus-TCP is to refer the Getting started Guide (found here) Another way is to start with the pre-configured demo application project (found in this directory). That way you will have the correct FreeRTOS source files included, and the correct include paths configured. Once a demo application is building and executing you can remove the demo application files, and start to add in your own application source files. See the FreeRTOS Kernel Quick Start Guide for detailed instructions and other useful links.

Additionally, for FreeRTOS-Plus-TCP source code organization refer to the Documentation, and API Reference.

Getting help If you have any questions or need assistance troubleshooting your FreeRTOS project, we have an active community that can help on the FreeRTOS Community Support Forum. Please also refer to FAQ for frequently asked questions.

Also see the Submitting a bugs/feature request section of CONTRIBUTING.md for more details.

Note: All the remaining sections are generic and applies to all the versions from V3.0.0 onwards.

Upgrading to V3.0.0 and V3.1.0 In version 3.0.0 or 3.1.0, the folder structure of FreeRTOS-Plus-TCP has changed and the files have been broken down into smaller logically separated modules. This change makes the code more modular and conducive to unit-tests. FreeRTOS-Plus-TCP V3.0.0 improves the robustness, security, and modularity of the library. Version 3.0.0 adds comprehensive unit test coverage for all lines and branches of code and has undergone protocol testing, and penetration testing by AWS Security to reduce the exposure to security vulnerabilities. Additionally, the source files have been moved to a source directory. This change requires modification of any existing project(s) to include the modified source files and directories. There are examples on how to use the new files and directory structure. For an example based on the Xilinx Zynq-7000, use the code in this branch and follow these instructions to build and run the demo.

FreeRTOS-Plus-TCP V3.1.0 source code(.c .h) is part of the FreeRTOS 202210.00 LTS release.

Generating pre V3.0.0 folder structure for backward compatibility: If you wish to continue using a version earlier than V3.0.0 i.e. continue to use your existing source code organization, a script is provided to generate the folder structure similar to this.

Note: After running the script, while the .c files will have same names as the pre V3.0.0 source, the files in the include directory will have different names and the number of files will differ as well. This should, however, not pose any problems to most projects as projects generally include all files in a given directory.

Running the script to generate pre V3.0.0 folder structure: For running the script, you will need Python version > 3.7. You can download/install it from here.

Once python is downloaded and installed, you can verify the version from your terminal/command window by typing python --version.

To run the script, you should switch to the FreeRTOS-Plus-TCP directory that was created using the *Cloning this repository* step above. And then run python <Path/to/the/script>/GenerateOriginalFiles.py.

To consume FreeRTOS+TCP

Consume with CMake If using CMake, it is recommended to use this repository using FetchContent. Add the following into your project's main or a subdirectory's CMakeLists.txt:

- Define the source and version/tag you want to use:

```
FetchContent_Declare( freertos_plus_tcp
  GIT_REPOSITORY https://github.com/FreeRTOS/FreeRTOS-Plus-TCP.git
  GIT_TAG        master #Note: Best practice to use specific git-hash or tagged version
  GIT_SUBMODULES "" # Don't grab any submodules since not latest
)
```

- Configure the FreeRTOS-Kernel and make it available
  - this particular example supports a native and cross-compiled build option.

```
set( FREERTOS_PLUS_FAT_DEV_SUPPORT OFF CACHE BOOL "" FORCE)
# Select the native compile PORT
set( FREERTOS_PLUS_FAT_PORT "POSIX" CACHE STRING "" FORCE)
# Select the cross-compile PORT
if (CMAKE_CROSSCOMPILING)
  # Eg. Zynq 2019_3 version of port
  set(FREERTOS_PLUS_FAT_PORT "ZYNQ_2019_3" CACHE STRING "" FORCE)
endif()

FetchContent_MakeAvailable(freertos_plus_tcp)
```

Consuming stand-alone This repository uses Git Submodules to bring in dependent components.

Note: If you download the ZIP file provided by GitHub UI, you will not get the contents of the submodules. (The ZIP file is also not a valid Git repository)

To clone using HTTPS:

```
git clone https://github.com/FreeRTOS/FreeRTOS-Plus-TCP.git ./FreeRTOS-Plus-TCP
cd ./FreeRTOS-Plus-TCP
git submodule update --checkout --init --recursive tools/CMock test/FreeRTOS-Kernel
```

Using SSH:

```
git clone git@github.com:FreeRTOS/FreeRTOS-Plus-TCP.git ./FreeRTOS-Plus-TCP
cd ./FreeRTOS-Plus-TCP
git submodule update --checkout --init --recursive tools/CMock test/FreeRTOS-Kernel
```

Porting The porting guide is available on this page.

Repository structure This repository contains the FreeRTOS-Plus-TCP repository and a number of supplementary libraries for testing/PR Checks. Below is the breakdown of what each directory contains:

- tools
  - This directory contains the tools and related files (CMock/uncrustify) required to run tests/checks on the TCP source code.
- tests
  - This directory contains all the tests (unit tests and CBMC) and the dependencies (FreeRTOS-Kernel/Litani-port) the tests require.
- source/portable
  - This directory contains the portable files required to compile the FreeRTOS-Plus-TCP source code for different hardware/compilers.
- source/include
  - The include directory has all the 'core' header files of FreeRTOS-Plus-TCP source.
- source
  - This directory contains all the [.c] source files.

Note At this time it is recommended to use BufferAllocation_2.c in which case it is essential to use the heap_4.c memory allocation scheme. See memory management.

Kernel sources The FreeRTOS Kernel Source is in FreeRTOS/FreeRTOS-Kernel repository, and it is consumed by testing/PR checks as a submodule in this repository.

The version of the FreeRTOS Kernel Source in use could be accessed at ./test/FreeRTOS-Kernel directory.

CBMC The test/cbmc/proofs directory contains CBMC proofs.

To learn more about CBMC and proofs specifically, review the training material here.

In order to run these proofs you will need to install CBMC and other tools by following the instructions here.
